The great remedy for all our troubles lies in convincing all influential people in this country that we really must make great radical changes. I have known the subscribers of money to a large technical college in England (the members of its governing board) to laugh, every one of them, in private over the idea that such an institution could do any good to the trade of their town.

How could it possibly do any good when there was such a spirit of unbelief among such people? We must create in England what already exists in Germany and France, and to some extent in America—a belief in the importance of scientific training everywhere. At present there is utter unbelief, and it is due to a bad system of education, which keeps everybody out of sympathy with everything scientific. It is terrible to hear our designers of bridges and steam engines and dynamos and great engineering schemes laugh at science and calculation, especially when one knows that foreign engineers are sneering at our best men; but it is well to know that, in spite of their laughter, our engineers are doing their very best to make use of all the true science that they have ever learnt; it is like gold leaf—very thin, but it serves a useful purpose. What they see clearly is the uselessness to God or man of such a so-called scientific training as they themselves had; they do not dream that there is a real scientific training possible by which useful mathematical and other weapons for solving all sorts of practical problems, handy to use and always ready, may become part of the mental machinery of the average man.

Four hundred years ago, reading, writing and cyphering were taught badly, and practical men looked upon them as things good to forget, things good for priests. If a layman could read or write, he was probably a useless person who, because he could not do well otherwise, took to learning. What a man learnt was clumsily learnt; if he learnt much, he was fit for nothing but learning; usually he learnt little with great labour, and made no use of it; therefore reading, writing and cyphering seemed useless. Do they seem now so very useless; now that everybody can learn them fairly easily? It is not so easy now to say that a man is useless merely because he can read, write or cypher. When I was an apprentice, and no doubt it is much the same now, if an apprentice was a poor workman with his hands, he often took to some kind of study, which he called science. In fact, science got to be the sign of a bad workman. But if workmen were so taught at school that they all really knew a little science, science would no longer be laughed at. When a civil engineer or electrical engineer fails because he has no business habits, he takes to calculation and the reading of so-called scientific books, because it is very easy to get up a reputation for science. The man is a bad engineer in spite of his science, but people get to think that he is an unpractical engineer because of his scientific knowledge.

Germany has an enormous advantage just now in this, that all thinking Germans, all influential men, believe that their great success in commerce and manufacture has come through physical science. Every manager and foreman, every captain of any kind of industry in Germany and Switzerland, has passed with honour through the science classes of a great technical school. The money that used to flow towards religious institutions now finds its way towards the greater and greater development of scientific education, so that Germany is getting covered with universities of science.

The open-hearth process has enabled German ores of iron to be used in steel manufacture. The war-earthquakes have stirred up the German people to new life, have produced enthusiasm, and made all kinds of ambition respectable. Any one who knew such a tumble-down, poverty-stricken town as Hanover forty years ago would not recognise it now. There are miles of streets of the brightest shops in Europe; at any time of the day or night one can read a small print newspaper in these streets; the streets throng with traffic, and the electric tram-cars have extended the city far into the country; and so it is in hundreds of towns, and manufactures flourish in thousands of places where the hare and partridge used to have the scenery to themselves. I do not think that the progress of Germany would have been half so rapid had it not been for the scientific education of the German leaders, but it is absurd to say that all this progress is due to science. The fact is that the whole world is developing its natural resources. England had the start; every country that has coal and iron, or their equivalents, is competing with England. The countries of greatest natural resources can afford to neglect their scientific education longer than others; but, sooner or later, knowledge and method and character must tell. If countries are equal in their natural advantages, victory must remain with that one in which there is the best education.

I have hitherto been reviling only the higher education in England. Until quite recently there was no primary education to revile. Let me put before my readers a true contrast. In Scotland, at any time during the last 100 years and more, if in the very poorest parish there was a boy of promise, a boy who showed a fondness for reading, for learning, for taking in what then and now goes under the name of education, a fondness for coming into contact with great minds through books—the success of that boy in life was absolutely sure. However poor his parents might be, however remote his humble home might be from civilisation, he was sent to the university, and got his chance. His nation gloried in his success, even if his own poor country had to be left by him for the richer field of England. Of all the great doctors and ministers and scholars of Scotch blood now to be found in London, only a very few can say that they were not exceedingly poor in their youth. Now contrast such a boy's chances with those of a clever English boy some years ago. Why, until the ever-to-be-praised Science and Art Department gave him a chance, a poor English boy, however promising, was compelled to eat his heart out in unavailing regret, was taught that it was a sin to think of bettering his condition, was taught that a decent education was as remote for him as for the cattle he tended.

I believe that this difference was due to the fact that in Scotland everybody thinks well of a good education, of knowledge, of mental power, because he himself can think, whereas in England education is looked upon with contempt, because there is not one labourer in a thousand who can think.

I do firmly believe that the Prince Consort saved this nation from utter defeat, and that if we are not yet to be defeated we must do as he would have continued to tell us to do. Had he lived till now, this country would not merely have the beginnings of a development of art and science; it would be covered with educational institutions whose most important object would be scientific study, a secondary leaning to literature not being neglected. As it is, we have the merest dust of his mind expanded into a wonderful Science and Art Department, which is criticised adversely only by the very ignorant or the very prejudiced. Only people like myself, whose whole life has been a pæan of gratitude for what that department has done for me and mine, who have seen in thousands of cases that it has redeemed otherwise wasted lives with enormous benefit to our industries, are really in a position to imagine how much that great man might have done for us if he had lived.

For one thing, just as the Science and Art Department is the envy and admiration of foreigners; just as it is an English institution, made to fit England and no other country, so he would have developed scientific education in England on lines utterly different from the soul-destroying system of Germany or its imitation in America.

Consider a scientific German as you know him. Say that he is twenty-three or twenty-five years of age, and he is about to enter business. From the age of seven or less he has trudged to school, perhaps at 7 o'clock in the morning, with a bag of books of half his own weight. He had a short interval for dinner, and went on to

6 o'clock at night. And he went on like that till now. There is no fact in all his school books that he has not heard a thousand times. He has had Goethe's maxims so drilled into him that he is "thorough" in every detail. I can imagine one Englishman in a hundred, after such a training, patiently turning over the muck heap of his knowledge; his eye would not gleam with any enthusiasm, but rather would glaze with envy and jealousy at the undeserved success of quite ignorant persons. And yet he would have knowledge, and know in his way how to use it; and it is because Germany has so many thousands of men trained in this way that she is certainly beating us to-day. They may be rather heavily loaded with learning, and I know that decently taught Englishmen who spent less than half the time at studies twenty times more interesting would beat them hollow in manufacture or research, would be the reverse of dull, and would be good citizens; yet the Englishmen I want only exist as yet by ones and twos, and such Germans are numerous. But just think of it! Here we are, a hard-headed, obstinate, cool race of men, who have had no end of chances in our safe little island, whilst our enemies were fighting among themselves, with coal and iron and the influx of good foreigners to set us first in the new field, and we have more than half of all the wealth of the world, and all that is needed for our keeping our good things is that we should believe them to be possibly evanescent; that there really is a chance that some better equipped nation may take them away from us, and therefore that we ought to prepare ourselves to fight for them. We have many chances in our favour and we hardly use them; the competing foreigner is very energetic, and cultivates his smallest chances. JOHN PERRY.

---

## HUMAN BABIES: WHAT THEY TEACH.

AN investigator anxious to obtain information as to the relationship of a particular species puts the question "What characters do the young stages exhibit?" and in order to answer that question he makes a study of the developmental phases exhibited by those stages. He may argue that if he finds certain characters in the young stages indicative of, and adapted to, habits of life which the adults do not possess, then there must have been a time in the ancestry of the species when such habits of life were of particular value, otherwise they would never have been developed. Or he may simply give, as the reason for his method of research, the concise statement "ontogeny repeats phylogeny," or he may hold to the theory of acceleration of development—which is more than a theory, because it is an actual fact of palæontology—that the characters of adult ancestors tend to become the characters of youthful descendants, thus producing specific diversity, without the necessity for a theory of natural, or any other form of selection, merely by inequality in the rates of developmental acceleration in different stocks. Wherefore *vice versâ* the characters of youth must at one time have been adult characters; and their differences from those of the adult indicate the degree of different environment under which the adult ancestors lived.

The manner of expressing the reason for a method of research may vary; the method itself remains the same. To know the past history of an organism, study the young. That is a method of universal application. It is the guiding principle of all researches into the past history of organic beings. It becomes then equally applicable to man himself; and in that way the human baby becomes an object of scientific attention. To study the human baby in this manner, the aid of photography is important; it gives a permanent record of what would otherwise be forgotten.

The early attempts of a baby in the matter of progression are particularly instructive. The bipedal gait is not attainable, indicating that the bipedal ability of the human being is of quite recent acquirement. What the child does show is either a truly quadrupedal method of progression, as in Fig. 1, which is also said to be common among children of uncivilised parents, or a kind of falsified quadrupedal progression on the hands and knees, which obtains generally among children of civilised parents, owing no doubt to impediments of clothes, and to over-coddling. Both methods of progression point to the same conclusion, though, of course, the former is the better illustration—that the ancestors of man were animals accustomed to a quadrupedal gait.

The influence of this quadrupedal gait of the ancestors is very strong. The child really has to unlearn it, and to readapt its hind limbs before it can attain the bipedal method of progression. The necessity for such readaptation, and the difficulty of acquiring the balance which progression on hind limbs demands, make the child's early efforts at walking so difficult. Observe a child just able to balance itself momentarily on its hind limbs. The insecurity of the position is shown by the attitude of the arms—outspread to help the balance, and by the feet being planted widely apart. The imperfection of the hind limbs for a bipedal gait is particularly noticeable. The legs are not straight, but they are considerably bent at the knee. That bending is incorrect for a bipedal gait; but it is a necessity of a quadrupedal progression, and it is just the feature seen when a four-footed animal, such as a cat, is induced to stand on its hind legs. In learning to walk on its hind legs the baby has to make many alterations in the anatomy of its hind limbs to fit them for their new function; and the human ancestors, in order to pass from quadrupeds to bipeds, must have had to do the same.

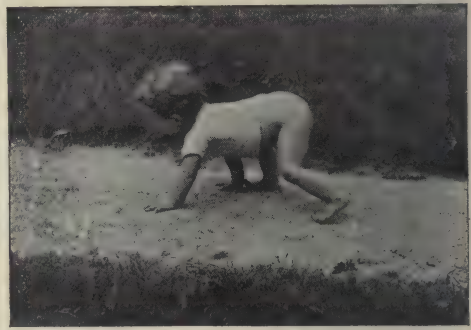

FIG. 1.—Child ten months old, on garden path.

There is another feature noticeable in regard to such a child in its first attempts at walking—the semi-clasped position of the hands. That is natural, it may be said. Certainly it is, but nevertheless a natural feature requires an explanation, and may be of particular significance. Such is the case here; the semi-clasped position of the hands is naturally and instinctively assumed because the human ancestors had for so many generations been bough-grasping animals, quadrupeds who lived among trees, who particularly used their hands for grasping boughs. Had they used the hands in a manner which always produced extension, then the extended position of the fingers would have become habitual.

Further evidence of the particular character which generations of bough-grasping ancestors have given to the hands of children may be obtained in this way. Get a series of school-children and ask them to hold their hands out straight. The failure of the majority of them to put out the fingers without some indication of the bough-grasping curvature will be very interesting. In some cases, especially among the younger children, the inward curve of the fingers will be very noticeable; and their inability to fully extend the fingers will be marked. A record of this inward curvature of the fingers may be obtained by photographing the extended hands when held against a dark background.

Even better evidence of the inherited bough-grasping instinct is afforded in Fig. 2. The child, about twelve months old, has picked up a flower-pot, and it has done so by dabbing the hand down upon it in the manner in which a monkey would catch at a branch. It has not made use of the thumb as an adult would do; but it has caught the rim of the flower-pot between the fingers and the palm of the hand, and in that manner has raised it up to its mouth. The sympathetic grasping attitude of the other hand may not be without significance; for although an arboreal animal like a monkey can sustain its weight by one hand, yet there would generally be a tendency to grasp with both hands at the same time in order to relieve the one arm of all the weight.

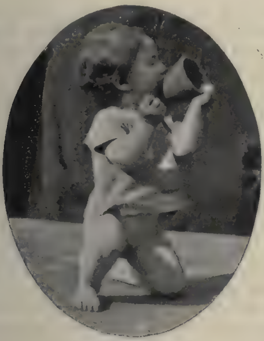

FIG. 2.—Child grasping a flower-pot.

A sympathetic action of this kind is very noticeable among children in regard to the use of the legs, and similarly it may be referred to the habits of arboreal ancestors. If a young child be put to hang on to a rope, which it will do very well long before it can support its weight in the ordinary human manner on its hind legs, or if it be merely lifted up by the hands, it will at once show a disposition to swing up its legs as if to catch at something. And this would be very natural in an arboreal quadruped. As soon as it grasped a bough with its arms, it would swing the legs up in order to grasp with the hind hands (the feet) either another bough, or in many cases the tree-trunk.

The inherited effects of grasping tree-trunks, or limbs with the hind hands are particularly marked in a young child. There is first of all, common to most babies, more or less of the bow-legged character which such trunk grasping would produce in arboreal animals. And then if a quite young child be held up so that its feet touch the ground, it will be seen that the outer portions of the feet rest on the ground, while the soles of the feet are not in position for being put flat, but are more or less opposed to one another in the manner suitable for trunk-grasping. Often, too, when the baby is lying down, the great flexibility of the ankle joint may be noticed; and the child will be seen to do, without an effort, what it would be very difficult for an adult to accomplish—it will, without bending the knees, bring the soles of the feet flat, opposite to one another. It is quite a common thing for a baby to turn the sole of its foot so that across the sole is in a straight line with the inside of the leg.

One habit after another, one action after another which a child performs may be seen to be quite out of keeping with what may be called human instincts, but exactly in accordance with the habits of arboreal animals. And so there is an accumulation of evidence, on the ontogeny repeating phylogeny principle, that the human ancestors were monkey-like animals, arboreal in their habits. One of the first things that the human baby does is to climb, and to climb persistently. It will climb its crib, or a footstool, or the fender, and particularly the stairs. Given a fair chance, and it will develop a perfect mania for stair-climbing and a bump of locality as regards the position of the stairs in the household geography—if such a bull may be permitted. Then it will make for the stairs on all occasions, to climb with crows of pleasure. It may experience tumbles, when it will lie and howl, not so much on account of injury as at the unexpectedness of the catastrophe. But on recovering it will at once make for the stairs again, showing how strongly the climbing instinct is developed.

And the climbing instinct lasts till later in life. Young boys, and girls too, must climb. The stairs themselves have become too small for their efforts then, but the bannisters remain, and they must climb up outside these, and hang on from various points which give any facility for arm exercise. The disposition for arm gymnastics is very marked in children who are not repressed in the unnecessary conventional manner. And it is a pity that it does not receive more systematic encouragement, because it would be beneficial for chest expansion in growing children. As matters stand now such exercise as is permitted favours leg development only, while all school work promotes contracted chests and rounded backs—at any rate with the girls. Boys are rather more fortunate. They are not troubled by an ever-rampant Mrs. Grundy preaching lessons on deportment. They retain the monkey habits of tree-climbing and bird-nesting. If any one reflects how important a prize to a hungry monkey a bird's nest of eggs must be, then he will understand how the inherited instinct can be so strongly developed among boys.

However, I am wandering somewhat from the human baby, and I will return thereto by asking consideration for what should be commonly observed in any family, a child with a pleased expression. There is one point in such expression which has not received due consideration, namely, the raising of lumps of flesh each side of the nose as an indication of pleasure. Accompanying this, though difficult to bring out in a photograph, may be seen small furrows, both in children and adults, running from the eyes somewhat obliquely towards the nose. What these characters indicate may be learnt from the male mandril, whose face, particularly in the breeding season, shows coloured fleshy prominences each side of the nose with conspicuous furrows and ridges. In the male mandril these characters have been developed, because being an unmistakable sign of sexual ardour they gave the female particular evidence of sexual feelings. Thus such characters would come to be recognised as habitually symptomatic of pleasurable feelings. Finding similar features in human beings, and particularly in children, though not developed in the same degree, we may assume that in our monkey-like ancestors facial characters similiar to those of the mandril were developed, though to a less extent, and that they were symptomatic of pleasure, because connected with the period of courtship. Then they became conventionalised as pleasurable symptoms.

Darwin's idea of Antithesis with regard to the expression of emotions does not commend itself. There is not space now to consider the subject fully; but it may be broadly stated that methods of expressing pleasure have all arisen from habits and actions employed in self-gratification—the satisfaction of the bodily requirements—either in self-nutriment or in procreation. But they may not be the actions employed by members of the species under its present-day conditions. And in the young they would certainly not be so; they would be the crystallised epitome, if such a term be allowed, of the habits and actions which proved successful with ancestors when they lived in a very different environment. Striking coloration of the face with ridges and scar-like markings would not now give pleasure to the sexes of the human species in their civilised condition; but the face of the male mandril is evidence of their having done so and still doing so among monkeys, and the practice of face painting, perhaps also of tattooing among savages, is evidence of the monkey habits having been inherited by the human species, and still finding favour among its members.

In the matter of pain, the idea that the expressions which indicate it go back to ancestors living under very different conditions is excellently brought out. Expressions would be the special muscular actions performed under the stimulus of a feeling of injury—such actions as were necessary to alleviate the pain, those necessary to prevent further pain, or to escape from the danger indicated by the pain, and those which were employed in revenge on the inflicter of pain, on the principle that destruction of the cause of injury would be the surest method of prevention.

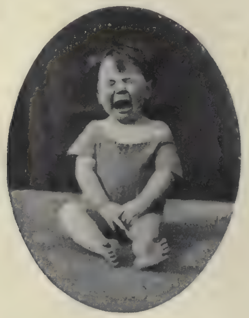

FIG. 3.—A child crying.

Therefore, one of the first things that pain prompts an animal to do is to exhibit and prepare its weapons of offence. In the case of the human baby such weapons of offence would be those which would have been employed by the pre-human ancestors. The picture of the crying child, Fig. 3, illustrates this. The peculiar squareness of the open mouth, caused by retraction of the lips at all four corners, is on purpose to exhibit the fighting weapons, the canine teeth; although, as a matter of fact, the canine teeth have not yet been developed. But the instinct to open the mouth so as to show canine teeth has been inherited from pre-human ancestors who habitually made use of these teeth in order to fight.

There is another feature in this picture, the tight closing of the eyes. This is to protect the eyes from injury during fighting. I photographed a cat which I pretended to strike. There was the same closing of the eyes; and, for a similar reason, a throwing back of the ears out of harm's way; and besides there was the paw ready to strike the assailant. I photographed another cat being teased. There was just the same opening of the mouth as in this picture of the baby, and the canine teeth, which were then disclosed, showed exactly what the cat's intentions were, that they were just the same as that expressed by the throwing open the portholes, and the running out the guns which we so often used to read of in accounts of men-of-war.

The lessons which the human baby can teach as regards the past history of its race are very numerous. I have only been able to glance at some of the more important; but they are sufficient to show that the subject is one of wide range and considerable interest.

S. S. BUCKMAN.

## *NOTES.*

LAST Thursday a combined meeting of the Royal Society and Royal Astronomical Society took place at Burlington House, when the observers who went away for the recent eclipse communicated the results of their observations. As the reports have not yet been published, we are unable to give an account of them. We have received from Prof. Langley a preliminary account, which we hope to print next week, of the expedition which went under his direction to Wadesboro, U.S.A., to observe the eclipse. The photographs he has obtained surpass any that have ever been taken at an eclipse, and speak volumes for the employment of instruments of great focal-length.

THE new physics laboratory of Owens College, Manchester, was opened on Friday last by Lord Rayleigh. Particulars as to the ceremony and the equipment of the laboratory will appear in our issue for next week.

THE Conference on Malaria, which was to have been held under the auspices of the Liverpool School of Tropical Medicine at the end of the present month, has been postponed in order to avoid clashing with the celebration of the Centenary of the Royal College of Surgeons of England and other gatherings.

WE regret to notice the death, at Manchester, on Monday last, of Dr. Daniel John Leech, a well-known physician, and professor of Materia Medica and Therapeutics in Owens College. As chairman of the Pharmacopœia Committee of the Medical Council he had charge of the publishing of the last edition of the British Pharmacopœia, and his name had been recently mentioned as the probable president of the British Medical Association. Dr. Leech was in his sixty-first year.

THE death is announced of Prof. Corrado Tommasi-Crudeli, secretary of the class of mathematical, physical and natural sciences in the Reale Accademia dei Lincei. Tommasi commenced his career in 1859 as demonstrator of pathological anatomy at Florence, after studying with Claude Bernard, of Paris, and Duchenne In 1862 he went to study pathology under Virchow, at Berlin; the next year he delivered a course of lectures on pathological histology at Florence, and in 1865 he was appointed professor ordinarius of anatomy at Palermo. During an outbreak of cholera in the following year, Tommasi rendered valuable services by his study of the disease and its mode of propagation, and published a well-known memoir on the subject. In 1870, Tommasi was called to Rome, where he was first appointed head of a newly-formed department of pathological histology. Later, he carried out extensive researches on the propagation of malaria. While his researches, conducted in conjunction with Klebs, have been superseded by recent discoveries, the general conclusions to which he was led have not only been substantially confirmed, but have received their true explanation in the new doctrine of the propagation of malaria by mosquitoes.

DURING the past week the summer meeting of the Institution of Mechanical Engineers has been held in London, and proved a successful gathering, interesting not only because of the various papers read (the titles of which, excluding an additional one, by Mr. E. Goffe, on "The Construction of 'Long Cecil,' a 4·7-inch Rifled Breechloading Gun in Kimberley during the Siege 1899–1900," have already been given by us), but from the fact of a number of members of the American Society of Mechanical Engineers being present. To these a most hearty welcome was accorded.

The thirty-second annual convention of the American Society of Civil Engineers was opened on Monday last at the Institution of Civil Engineers. The proceedings were inaugurated by an address of welcome from Sir Douglas Fox, the president of the Institution of Civil Engineers, and the presidential address was delivered and several discussions took place.

The Audiffret prize, of the value of 15,000 francs, has been awarded by the Academy of Moral and Political Sciences of Paris to Dr. Yersin for his discovery of the anti-bubonic serum. The prize is awarded at regular intervals for the "greatest devotion to scientific discovery."

The Pharmaceutical Society announces that the Salters' Company Research Fellowship is now vacant. The subject of the Fellowship is chemistry considered especially in its relation to pharmacology, that is, the application of the newest methods of scientific chemistry to the elucidation of pharmacological problems. The Fellowship is of the annual value of 100*l.*, and is tenable in the Research Laboratory of the Pharmaceutical Society for one year, but may be renewed under certain conditions, and the holder is expected to devote his whole time to original investigation. Candidates need not necessarily be pharmaceutical chemists or members of the Society. The last day for receiving applications is Saturday next.

The Balbi-Valier prize, of the value of about 120*l.*, has been awarded by the Venetian Institute of Sciences to Prof. Grassi, of Rome, for his work on the mosquito and its relation to malaria.

A prize of the value of 1000 marks is offered by the Scientific Society of Danzig, in connection with its 150th anniversary, for a paper on the geology of North Germany.

The German Society of Mechanical Engineers offers a premium of 60*l.* and a gold medal to the designer of the best system of high-speed electric railways for heavy traffic. Designs must be submitted by, at latest, October 6 next.

The Lavoisier Monument which is being erected on the Place de la Madeleine, Paris, in close proximity to the house in which the famous chemist lived for many years, will, according to the *Chemist and Druggist*, be formally inaugurated on July 27 by the French Minister of Public Instruction. The statue has been erected by international subscription under the auspices of the Paris Academy of Sciences. The sculptor is M. Barrias, and the monument will consist of a bronze statue of Lavoisier, on a pedestal, bearing on two sides bas-reliefs showing Lavoisier working in his laboratory with Mme. Lavoisier writing under his dictation, and Lavoisier expounding the result of his experiments at a meeting of the Academy of Sciences. The scenes have been created from authentic documents.

A monument has been erected to the memory of Dr. Jean Hameau, the obscure general practitioner of the Gironde, who, in 1836, published a study on viruses, in which he partly anticipated the discoveries of Pasteur. The statue was unveiled recently at La Teste de Buch, where Hameau practised. Addresses were delivered by Dr. Laude, the Mayor of Bordeaux and President of the Medical Syndicates Union of France, Prof. Lannelongue, of Bordeaux, and others. Hameau was born in 1779, and died in 1851. His claim to be considered a precursor of Pasteur has been publicly acknowledged by Prof. Grancher, and it is probable that had he been possessed of the laboratory accommodation and means of investigation available at the present day, the microbe theory of disease would have been established fifty years sooner than it was.

Prof. H. F. Osborn, of Columbia University and the American Museum of Natural History, has, according to *Science*, been invited to succeed the late Prof. Cope as vertebrate palæontologist of the Geological Survey of Canada.

Mr. W. E. D. Scott, curator of the ornithological department in Princeton, announces, says *Science*, that the British Museum has presented to the University two thousand mounted birds, specimens from India, Australia and the Malay Islands. Some time ago the University presented the British Museum with 250 sets of North American birds' eggs.

It is announced that the repairs to the Arctic steamer *Windward* have now been made, and the vessel was expected to sail by about July 1. The *Windward* will proceed directly, with a call at Disko, to Etah, North Greenland, Lieut. Peary's winter quarters, where instructions from him will doubtless be found, or if not, will be awaited. The vessel will take with her the maximum quantity of coal, additional lumber, oil, sugar, arms, ammunitions, provisions, scientific instruments and everything necessary for Lieut. Peary's work, including two new whale-boats, specially built at New Bedford, and thoroughly equipped in every detail. Upon the arrival of the *Windward* at Etah, Lieut. Peary will assume command, and further movements will be subjected to the conditions of his work and to his instructions. No passengers will be taken on the *Windward*, the Danish Government having qualified their permission to land at the Greenland ports, with conditions that tourists should not be carried. If Lieut. Peary has succeeded in carrying out his plans, that is to say, if he has discovered the North Pole, he will, says the *Scientific American*, return with the ship. If not, the supplies will be landed. It is possible that the *Windward* will bring back the Robert Stein party, which was landed near Cape Sabine by the *Diana* in August last.

A bottle has, it is reported, been found on the shore at Roundstone, co. Galway, containing a printed card directing the finder to forward the contents to Captain Ernest André, Polar Expedition Company, Sweden, and stating that it was thrown from Major André's balloon in the Arctic regions with a view to testing the ocean currents. The bottle has been forwarded to the Board of Trade.

Sets of volumes on naval architecture, and on the history of the British Navy, have been presented by the Institution of Engineers and Shipbuilders of Scotland to Prof. Arnold, of the Sheffield Technical School, as a token of appreciation of the lecture delivered by Prof. Arnold on "The Internal Architecture of Metals."

A meeting was held in the rooms of the Royal Meteorological Society some time ago to consider the question of a memorial to the late Mr. G. J. Symons, F.R.S., when it was resolved unanimously that the memorial should take the form of a gold medal, to be awarded from time to time by the Council of the Royal Meteorological Society for distinguished work in connection with meteorological science, and an executive committee was appointed to take the necessary steps for the raising of a fund for the purpose. The committee now appeal to the fellows and members of the societies with which Mr. Symons was associated, to the rainfall observers, and to all who have in any way benefited by his advice and assistance, to contribute to this memorial fund, which it is hoped may reach the sum of at least 750*l.* Contributions should be paid to Mr. W. Marriott, 70 Victoria Street, Westminster, S.W.; or to the "Symons Memorial Fund," Bank of England (Western Branch), Burlington Gardens, W.

An Anti-rabic Institute for India is, says the special Indian correspondent of the *Lancet*, at last an accomplished fact. After numerous delays, Government have stepped in and practically settled the difficulties. The Royal Army Medical Corps having an officer in Major D. Semple who had studied in Paris and Lille, determined to utilise his experiences, and the annual expense for sending soldiers to Paris was diverted for the new institute. The central committee of the proposed Pasteur Institute saw their opportunity and took over its control. With a capital of 70,000 rupees and a yearly grant of 19,500 rupees, the expenses of the new institute ought to be fairly well met. Residents in India may be congratulated that at last means are provided whereby European and native patients alike can be offered the best available treatment for the terrible disease of rabies.

Dr. L. Sambon and Dr. Low, the two medical men entrusted by the British Government with the perilous task of testing the possibility of guarding against malarial infection in the Roman Campagna, have, according to the *Lancet*, at length found a favourable place for their purpose. After rejecting various other localities as being for one reason or another unsuitable, they have selected a spot about two miles distant from Ostia, between Castel Porziana and Castel Fusano, and within five minutes' walk of the latter place. The site of their hut is on the edge of a "stagno," or swamp, forming part of the royal hunting demesne of Castel Fusano, and left undrained in order to preserve the wild boar, water fowl, &c., which frequent it. The hut will stand close to a canal containing a luxuriant growth of algæ and other aquatic plants, and within a stone's throw of a clump of pine trees, which forms the outskirts of the Castel Fusano pine forest. The few dwellings near are inhabited by peasants who constantly suffer from malaria and are infested by mosquitoes of the anopheles variety. Situated thus in the heart of the swamps surrounding the mouth of a large river, among the haunts of innumerable mosquitoes of the malarial variety, and in a locality notorious as one of the most deadly of the fever-stricken centres of the Roman Campagna, this dread and unhealthy spot appears to offer ideal conditions for the carrying out of the interesting but dangerous experiment now about to be begun. The two daring investigators hope to have everything in readiness early in the present month; in the meantime, their time is profitably occupied in studying the animal and insect life of the Campagna, collecting and examining frogs, lizards, bats, spiders, mosquitoes, and the like. They have already made some interesting observations, as, for example, that although the larvæ of anopheles are at this season apparently very few, the adult mosquitoes are collected in the houses in great numbers, being especially numerous near byres and stables. The King has graciously given his consent to the erection of the hut in the royal preserves, and the municipality of Rome are doing everything in their power to help the enterprise.

The annual general meeting of the Jenner Institute of Preventive Medicine was held on Friday last, when Dr. Macfadyen, the director, was able to state that the Institute's work had continued to progress. Among the new features added during the year were a physiological room, a room for incubating purposes, a laundry, a workshop, and a cold storage room. A Hansen apparatus for yeast culture had been presented, and considerable additions had been made to the library. Three papers were communicated to the Royal Society upon the influence of the temperature of liquid air and hydrogen upon bacterial life. Systematic investigations are being carried out in the bacteriological department upon enteric fever, tuberculosis, and the etiology of cancer. Special investigations were carried out for public authorities during the year, *e.g.* upon tubercle in milk, glanders, anthrax, &c., and investigations in a number of other directions have been and are being prosecuted with vigour.

The recent case of the Jenner Institute of Preventive Medicine *v.* Assessment Committee of St. George's, Hanover Square, was the means of raising once more the important question of the rateability of scientific societies. The Jenner Institute has unfortunately failed to establish its claim to exemption from the payment of rates. The Divisional Court decided that the Institute did not fulfil the conditions of the Act of Parliament exempting "any Society instituted for purposes of science, literature, or the fine arts exclusively." The preparation and sale of preventive and curative medicines was held by Mr. Justice Grantham to be the main object of the Institute, or as Mr. Justice Channell put it, "its main object was to dispense to the public the benefits of science." The Institute was not, therefore, "exclusively" devoted to the advancement of science. The Institute has, as a matter of fact, dispensed for the benefit of the public, and at a considerable loss, certain antitoxins which require the highest scientific skill in their preparation. The preparation of these substances has been at the same time a means of studying and improving the methods for producing immunity to given diseases. The aims in this respect have been of a purely scientific character, and in accordance with the main objects of the Institute, which are not, despite the Court's ruling, of a dispensing nature, except in so far as opportunity is afforded to medical men to test the value of certain antitoxins in the treatment of disease. The eminently useful aims of the Institute, which are carried out at great cost, might have been thought to bring it well within the intention of the Act, but the judicial interpretation of the word "exclusively" has formed the stumbling-block. It is to be feared that the expense of litigation may prevent the Institute from proceeding to an appeal. In any case, it is to be hoped that some steps will be taken to amend an Act, apparently devised for the benefit of scientific societies, but which, as interpreted by the Court, has little or no practical value. It is quite conceivable, as the law stands, that a claim for exemption might be defeated on the ground that a daily newspaper had been admitted to the reading-room of an institute, and that it was not, therefore, "exclusively" devoted to purposes of science.

The annual general meeting of the Marine Biological Association was held in the rooms of the Royal Society on June 27. The council reported that arrangements had been completed for the supply of sea-water, obtained from the open sea beyond the Plymouth Breakwater, for special experiments on the rearing of sea-fishes and other marine animals. Through the kindness of Mr. J. W. Woodall, the Association has had placed at its disposal a small floating laboratory, which is at present stationed at Salcombe. The periodical surveys of the physical and biological conditions prevailing at the mouth of the English Channel have been continued by Mr. Garstang at quarterly intervals for an entire year. Observations were taken at four fixed stations. They included serial temperature determinations at all depths, filtration of a definite column of water from bottom to surface with a "vertical net," and collections of the floating life at surface, mid-water and bottom, by means of a specially devised closing net. Mr. Garstang has also carried out a series of preliminary experiments on the rearing of sea-fish larvæ under different conditions, with a view to a solution of the difficulties hitherto encountered in regard to the practical work of sea-fish culture. The investigation of the fauna and bottom deposits of the shallow water grounds in the neighbourhood of Plymouth, upon a systematic plan, has been continued during the year.

A SUCCESSFUL trip has at last been made with Count Jeppelin's navigable balloon at Friedrichshafen on Lake Constance. On Saturday evening the ascent was prevented by an explosion of one of the segments of the balloon, and a similar accident is stated to have befallen one of Count Zeppelin's benzine motors. On Sunday evening, Count Zeppelin and four others made their first ascent, and after drifting with the wind, turned and tried to make headway against it; but the wind appears to have been too strong, and the balloon was quietly lowered to the lake, where the cars floated and the occupants were brought to shore without any damage. From another telegram dated July 2 (Monday) we learn that a successful ascent was made that evening. This must have been a second attempt, and it is stated that the ship travelled safely to Immenstadt, thirty-five miles from Friedrichshafen, and landed all well.

LONDON was again visited by a sharp thunderstorm about midday on Tuesday; the rainfall and hail during the storm amounted to 0·23 inch in Westminster. The weather has continued in a very unsettled condition, but, nevertheless, the mean temperature in the neighbourhood of London for the month of June exceeded the average by about 0·05. This result has been caused chiefly by the amount of cloud which, while making the days cool, has kept the nights relatively warm. The rainfall for the month was 0·66 inch above the average, and in some parts of England it was double the average.

THE *Lancet*, quoting from a Buenos Ayres review of hygiene, entitled *La Salud*, gives some interesting particulars concerning the plague. Formerly, according to a tradition common amongst certain tribes of South American Indians, wide-spreading fires used to sweep over the land. The inhabitants were in the habit of taking refuge in caves and dens of the earth. From time to time they poked out the branch of a tree, and if this when pulled in again showed no signs of burning they considered it safe to come out. So formerly when plague ravaged and desolated various countries the inhabitants shut themselves up in the cave of isolation and did not come forth until they learned that plague had disappeared. Nowadays, however, just as the Indian tribes possess herds of horses which they did not formerly possess, and are able by these means to stamp out pampas fires, so that there is no need to take refuge in a cave, so also modern cities possess hygienic knowledge and conditions which render isolation unnecessary, and a general dissemination of plague throughout Europe and America is as impossible as a fire which should affect the whole pampas. In India and in China only those persons succumb who live under grossly unhygienic conditions. With reference to the recent outbreak of plague in Argentina, *La Salud* says, "It would be greatly to the honour of the Argentine Republic if she would invite other countries to a conference to consider the question of meeting plague, if not actually by abandoning all international action yet by leaving commerce perfectly free and by treating the disease wherever it appears exactly like any other infectious disease which assumes endemic characters."

THE annual report of Sir George Nares, F.R.S., acting conservator of the Mersey, has just been issued, and shows that considerable work has been done by the sand-pump dredgers *Brancker* and *G. B. Crow* at the Queen's Channel Bar and at certain shoals in the Queen's and Crosby Channels, at the entrance to the river. For several months the surveys show considerable improvement, many of them having no soundings less than 27 ft. below low water spring tides within the dredged cut. Though there has been slight shoaling at the outer end or the north side of the channel, several good lines of sounding run the full length of the cut with not less than 27 ft. During the year 2,067,000 tons were dredged in Queen's Channel, 1,839,000 tons taken from shoals in that channel, and 2,735,000 tons from shoals in Crosby Channel, making a total of 6,659,000 tons, while since the commencement of the operations 45,148,860 tons of sand have been removed. The number of inward and outward bound vessels passing through Queen's Channel last year was 45,158, against 44,376 in the previous year, and 35,932 in 1893. The daily average of last year was 124 against 98 in 1893. The total using all the channels increased from 41,439 in 1893 to 50,964 in 1898, and 52,216 last year. The sand removed from the river between Liverpool and New Brighton in 1899 was 1,374,670 tons. In the same period 1,375,272 tons of silt and detritus were raised from the Manchester Ship Cana and deposited at sea.

THE idea of substituting electricity for horse-traction on canals has not been so widely developed as one would have expected to see, but some experiments of an instructive nature (*Engineering*, June 22) have been made by a German firm on behalf of the Prussian Government, wherein electric locomotives were employed for this purpose, and the mode of working may be briefly stated as follows:—A section of the Finow Canal, which forms a portion of the waterway between Berlin and Stettin, was chosen, embodying as it does physical difficulties with reverse curves, &c. On the towing-path a meter-gauge track of special design with overhead conductor was laid, on which the electric motor tows the barges; and owing to the deficiency of adhesive weight a steel rack is bolted to the permanent way, and the rack-rail system is adopted. In spite of many difficulties the experiments proved that the system was capable of meeting all requirements, and worked with apparent ease. This is very satisfactory, the more so because in one place, we are told, the line was raised 9 feet 6 inches above the towing-path with approaches of 1 in 8½ gradients. The electric motor used, we are informed, developed from 14 to 15 horse-power, much more than was necessary; but this was intentionally provided in view of further experiments to deal with the possibility of electric traction for barges of a heavier type.

IN NATURE for September 1, 1892, Prof. D. Kikuchi announced the foundation by an Imperial ordinance of an earthquake investigation committee in Japan. The objects of the committee were to study the nature of Japanese earthquakes and their distribution in time and space, to discover any means of lessening their disastrous effects, and if possible to ascertain laws by which their occurrence might be predicted. During the eight years of its existence much successful work has been done by the committee in two of these directions. They have accumulated and discussed many series of observations and records, and have conducted numerous experiments on the fracturing and overturning of columns and on the type and material of building best suited to resist a strong shock. The results are printed partly in Japanese papers; partly, we are glad to see, in their "Publications in Foreign Languages," the third and fourth numbers of which have appeared this year. If abstracts of the former could be given either in English or French, the debt we already owe to Japanese seismologists would be greatly increased.

THE Verein zur Förderung des Unterrichts in der Mathematik und den Naturwissenschaften held its annual meeting at Hamburg in the first week in June. This association, which numbers some 900 members, includes many teachers in the higher schools of Germany among its ranks, and it has taken part in the preparation of reports on physical apparatus suitable for teaching purposes. The programme included, among other subjects of papers, the teaching of geometry of position, wireless telegraphy, experiments with liquid air, flight of birds, the International Catalogue, and the preservation of natural objects of interest in Germany.

We are indebted to Prof. P. H. Schoute for a paper on the locus of the centre of hyperspherical curvature for the normal curve of $n$ dimensional space. In a previous paper the author pointed out that the characteristic numbers of the locus of the centre of hyperspherical curvature are lowered if some of the points of the given rational curve lying at infinity coincide. At present Prof. Schoute traces for a special case the amount of these lower numbers, namely, for the case where the given curve is the "normal" curve of the $n$ dimensional space in which it is situated. According to the final result, the characteristic numbers of the locus of the centre of hyperspherical curvature for the normal curve are respectively $2n-1$, $3n-3$, $4n-7$, $5n-13$, $6n-21$, .... $2n-1$, from which it follows that they do not change if taken in reverse order.

A report on dietary studies of Harvard and Yale University boat crews, conducted by Prof. W. O. Atwater and his assistant, Mr. A. P. Bryant, forms *Bulletin* No. 75 of the U.S. Department of Agriculture. These studies were undertaken primarily to secure data regarding the food requirements of men performing severe muscular work, and they lead to the conclusions that the actual food consumption of people in general is regulated more or less by the supply at their disposal and their tastes and appetites; but that it is justifiable to suppose that in a general way the difference between the food of athletes and that of other people represents a difference in actual physical need, even if neither is an accurate measure of that need. The energy of the food consumed per man per day in the dietary studies of university boat crews was found to exceed by 400 calories, or about 10 per cent. the amount found, as the average of fifteen dietary studies among college clubs in different parts of the country, while the protein in the studies of the university boat crews was 48 grams, or 45 per cent. larger in amount.

In the *Rendiconti del R. Istituto Lombardo*, Dr. Benedetto Corti briefly describes the results of a study of the Diatomaceæ of the lakes of Brianza and Segrino. Of a total of eighteen species of diatoms observed in the lake of Montorfano, two (*Synedra lunaris* and *Stauroneis platystoma*) were Alpine in character, and were supposed by the author to represent the remains of a quaternary diatom flora. This view has been confirmed by a more extended study of the other lakes of Brianza and Segrino, which revealed the presence of fifteen species of diatoms peculiar to the Alpine zone out of a total of seventy-two. Of the Alpines, however, only one, viz. *Navicula firma*, was found in the lake of Sartirana. There is a decided affinity between the diatom flora of these lakes and that of the lake of Palù in the Malenco valley, and that of Poschiavo in the Engadine.

No. 17 of the "North American Fauna," now in course of publication by the Biological Division of the U.S. Department of Agriculture, is devoted to a revision of the North American voles, or "field-mice," of the genus *Microtus*, by Mr. V. Bailey. As the work is based on the examination of between 5000 and 6000 specimens, including typical representatives of every species, from more than 800 different localities, it ought to be exhaustive. The genus, which is divided into nine subgeneric groups, is taken to include no less than seventy distinct specific and sub-specific modifications, three of which are described for the first time. It is noticed that the development of oil-glands and musk-glands is most conspicuous in the aquatic members of the group, and least so in those inhabiting the driest regions. Those forms which are most exposed to light and dryness are the palest, while the deepest and richest tones of colour are developed in those from damp and shaded localities. Attention is directed to the importance of placing every possible check on the increase of these little mammals, and of reducing their numbers when they become unusually abundant.

In its *Bulletin* No. 12, the department just mentioned publishes a useful report, by Mr. P. S. Palmer, on the legislation for the protection of birds, other than game-birds, now in force in the United States. The author states that many insectivorous birds are still unprotected; and that the laws relating to such birds in general lack uniformity in different parts of the States; this diversity in the laws being illustrated by a map. The report closes with a digest of the bird-laws of the different States. The need of further legislation is strongly emphasised.

In this connection may be noticed a pamphlet on the food of wild birds in this country, issued by the Yorkshire College and the Joint Agricultural Council of Leeds and the East and West Ridings. In this useful publication attention is called to the fact that birds very largely affect both sides of the farmer's balance-sheet; and that while, unfortunately, the damage they do is readily detected, the great services they render can only be appreciated by those who take pains to investigate the subject. The "pros and cons" in regard to each particular bird seem to be very fairly considered.

The July number of the *Journal of Conchology* contains an interesting sketch of the life and career of the late Mr. Lovell Reeve, the well-known conchologist, with extracts from his diary and correspondence.

No fewer than three books dealing with the life and work of the late Prof. Huxley are being prepared at the present time. Messrs. Macmillan and Co. will issue the biography of his father by Mr. Leonard Huxley, and a volume on the professor is to be added to Messrs. Putnam's Sons' "Leaders of Science" series from the pen of Mr. P. Chalmers Mitchell; while a third work is to be contributed to Messrs. W. Blackwood and Sons' "Modern English Writers" series by Mr. Edward Clodd.

Messrs. Charles Griffin and Co., Ltd., have sent us the seventeenth annual issue of the "Year-Book of the Scientific and Learned Societies of Great Britain and Ireland," comprising lists of the papers read during 1894 before societies engaged in no fewer than fourteen departments of research. The serial, which is too well known to need more than a brief reference here, contains much information of service to literary and scientific men. It would be yet more valuable if the officials of certain societies, against whose entry the words "No Return" appears, could be induced to furnish the compiler with the titles of the papers presented to their respective institutions.

A new edition (the fifth) of "The Microtomist's Vade-Mecum," by Arthur Bolles Lee, has just been issued by Messrs. J. and A. Churchill. Considerable changes have been made in the present edition, the whole work having been very carefully revised since the last edition appeared nearly four years ago. The text has undergone condensation throughout, making it possible for much new matter to be added without increasing the size of the volume.

More and more space, we are glad to see, is being given in the popular magazines to articles dealing in a greater or less degree with scientific subjects, and in the monthlies for July that have reached us we notice the following contributions of this character:—In *Pearson's Magazine* Prof. Simon Newcomb explains to the lay reader in simple language, and by the aid of diagrams, "How the Planets are Weighed"; while Dr. F. A.

Cook, who was attached to the Belgian Antarctic Expedition, discourses pleasantly on "The Possibilities of Reaching the Four Poles." In *Good Words* Mr. E. W. Maunder writes on "The Lords of Cold" (the title, it may be noted, is borrowed from a line in Plumptre's "Dante"), the article being a study in stellar perspective. In the same magazine is also to be found a contribution, by Mr. Aflalo, on "How Wild Creatures Feed." *Chambers's Journal* always contains at least one article of scientific interest; the present number has in it papers, entitled "Tropical Diseases and Cures" and "Alcohol from Paper and Sawdust."

THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. G. A. S. Bell, R.N.; a Ring-tailed Lemur (*Lemur catta*) from Madagascar, presented by Miss M. C. Rawcliffe; a Common Duiker (*Cephalophus grimmi*, ♂) from South Africa, presented by Mr. J. E. Matcham; five Wild Cats (*Felis catus*) from Inverness-shire, presented by Mr. George J. Bailey; a Levaillant's Amazon (*Chrysotis levaillanti*) from Mexico, presented by Mr. J. Farmer Hall; a Royal Python (*Python regius*) from West Africa, presented by Mr. Benjamin Stewart; an Alpine Newt (*Molge alpestris*), nine Black Salamanders (*Salamandra atra*), two Slowworms (*Anguis fragilis*) from Switzerland, presented by the Rev. J. W. Horsley; a Common Viper (*Vipera berus*), British, presented by Mr. G. Alan Marriott; a Common Duiker (*Cephalophus grimmi*, ♀) from South Africa, a Syrian Bear (*Ursus syriacus*) from Western Asia, a Cheetah (*Cynoelurus jubatus*) from India, two Black-faced Kangaroos (*Macropus melanops*, ♂, ♀) from Tasmania, six Wrinkled Terrapins (*Chrysemys scripta rugosa*) from the West Indies, an Amboina Box Tortoise (*Cyclemmys amboinensis*) from the East Indies, five Mississippi Terrapins (*Malacoclemmys geographica*), a Prickly Trionyx (*Trionyx spinifer*) from North America, three Annulated Terrapins (*Nicoria annulata*) from Western South America, deposited; a Three-toed Sloth (*Bradypus tridactylus*) from British Guiana, purchased.

## OUR ASTRONOMICAL COLUMN

EPHEMERIS FOR OBSERVATIONS OF EROS.—The following computed positions for July are from the ephemeris prepared by Herr F. Ristenpart (*Astronomische Nachrichten*, Bd. 152, No. 3643).

*Ephemeris for 12h. Berlin Mean Time.*

| 1900. | | R.A. h. m. s. | | Decl. ° ′ ″ |
|---|---|---|---|---|
| July 5 | ... | 0 54 6·51 | ... | +14 13 22·3 |
| 7 | ... | 57 27·78 | ... | 14 50 33·5 |
| 9 | ... | 1 0 48·24 | ... | 15 27 55·3 |
| 11 | ... | 4 7·89 | ... | 16 5 27·7 |
| 13 | ... | 7 26·71 | ... | 16 43 10·8 |
| 15 | ... | 10 44·66 | ... | 17 21 5·0 |
| 17 | .. | 14 1·68 | ... | 17 59 10·8 |
| 19 | ... | 17 17·70 | ... | 18 37 28·1 |

| 29 | ... | 33 19·70 | ... | 21 51 55·1 |
| 31 | ... | 1 36 27·93 | ... | +22 31 26·5 |

MEASURES OF EROS.—*Harvard College Observatory Circular* (No. 51) contains the results of the measurements of photographs obtained during the years 1893, 1894 and 1896, giving the positions of the planet during those years. The complete discussion of the measures is being prepared for a volume of the Observatory *Annals*, but the numbers here published show that at the Harvard College Observatory there is the means of tracing the path of any object since 1890, during the times in which it was moderately bright, with nearly as great accuracy as if a series of observations had been taken of it with a meridian circle.

TOTAL ECLIPSE OF THE SUN, MAY 28.—M. Deslandres communicates the report of his work in connection with the recent eclipse to the *Comptes rendus* (vol. cxxx. pp. 1691–1695). His programme comprised four classes of investigation:—(1) velocity of corona; (2) ultra-violet spectrum of corona and chromosphere; (3) infra-red spectrum of corona; (4) photography of corona.

Observing visually with a powerful grating spectroscope, he found by the inclination of the corona line that on the west side of the equator the corona appeared to have a more rapid speed of rotation than the disc. The photographic spectra taken for this purpose are too faint for measurement.

The ultra-violet spectra were obtained with spar quartz prismatic cameras, ten plates being obtained showing good images down to λ 3000.

The investigation of the infra-red radiation from the corona was undertaken with a view of providing a possible means of observing the corona without an eclipse, and the results would indicate that the corona is specially rich in these calorific radiations. M. Deslandres states that at his station, Argamasilla, Spain, totality was five seconds shorter than the calculated time.

## THE ROYAL OBSERVATORY, GREENWICH.

IT is customary for the Astronomer Royal to present his annual report to the Board of Visitors of the Royal Observatory on the first Saturday in June, but as it is easier to transfer such a function to another date than to change the time of a total eclipse of the sun, the usual day of meeting was adjourned until June 26 last. On this day, the weather, however, did not quite come up to summer standard; but fortunately the rain held off, and the afternoon proved sufficiently fine to allow the numerous visitors to inspect the buildings and instruments. As is customary, we give below a brief *résumé* of the report.

### BUILDINGS.

The building of the new observatory so near to the boundary of the grounds has necessitated an alteration in the position of the old fence, to show the building off more effectively, so that provision has been made in the Navy estimates to put the fence further away, and the plans for this are now under consideration. This building also includes the new library rooms, and we learn that the removal of the books to their new position was completed in March last. The opportunity has also been utilised for their rearrangement and for the preparation of a new catalogue, both of which, we are told, were much needed. Not only is the rearrangement of the books practically complete, but good progress has also been made with the formation of the card catalogue, a system which is to be highly recommended.

### TRANSIT CIRCLE.

The sun, moon, planets, and fundamental stars have been regularly observed on the meridian as in previous years. The number of observations made from 1899 May 11 to 1900 May 10, is as follows:—

| | |
|---|---|
| Transits, the separate limbs being counted as one observation ... ... ... ... | 10,712 |
| Determinations of collimation error ... ... | 297 |
| Determinations of level error ... ... ... | 684 |
| Circle observations ... ... ... ... | 10,001 |
| Determinations of nadir point (included in the number of circle observations) ... ... | 674 |
| Reflexion observations of stars (similarly included) ... ... ... ... ... ... | 637 |

The number of stars observed in 1899 is about 5000.

An unusually large number of observations was obtained in the three months, August–October, the average number of transits observed being more than 1300 each month. From November to the date of the report, in consequence of the cloudy weather, the average has been only half this number.

The apparent correction for discordance between the nadir observations and stars obtained by reflexion for 1899 was found to be slightly larger—namely, −0″·41—than that of last year, which was −0″·36.

The results of recent years are as follows:—

| | Mean | Range in Yearly Means |
|---|---|---|
| 1880–1885 | −0″·34 | From −0″·29 to −0″·45 |
| 1886–1891 | +0·03 | ,, −0·12 to +0·09 |
| 1892–1898 | −0·30 | ,, −0·25 to −0·36 |

Observations of level and nadir have been made, when practicable, three or more times on the same day, and diurnal changes similar to those referred to in the last report have been found in 1899. The observations of level taken within three hours of noon and midnight give corrections of +0″·30 and +0″·18 respectively, to those made within three hours of 6 p.m. Similarly the observations of nadir near noon and midnight give corrections of +0″·17 to those made within three hours of 6 p.m.

In view of this systematic diurnal movement of the instrument and of the large number of observations of azimuth stars in recent years, it seems probable that the limit of accuracy obtainable by the use of double transits for the determination of the positions of the close polar stars has been reached, as this involves the assumption that the azimuth error remains constant for twelve hours at least. It has therefore been arranged to use these stars for determination of azimuth error, by means of their tabular right ascensions, and to keep the observations for improvement of the tabular place only when the azimuth error has been determined by at least three pairs of close polar stars above and below pole on the same evening.

The correction for the R–D discordance, found for 1899, is +0″·080+0″·218 sin Z.D. The coefficient of sin Z.D. was about +0″·6 from 1881 to 1894, diminished to +0″·41 and +0″·37 in 1895 and 1896, to +0″·10 in 1897 and 1898, and has now increased to +0″·22.

The observations of the zenith distances of pairs of stars directly and by reflexion, alternately on alternate nights, have been discontinued. The observations made in the four years, 1895, 1896, 1897 and 1898, show a satisfactory agreement with the ordinary observations, reflexion and direct at the same transit, confirming the striking diminution in the value of the R–D discordance in 1897 and 1898 as compared with 1895 and 1896.

The colatitude of the transit circle, as found from observations of about 600 stars in 1899, is 38° 31′ 21″·76, differing by −0″·14 from the adopted value. The corresponding values of the correction to the adopted colatitude found in 1897 and 1898 are −0″·17 and −0″·15, and it may be noticed that the R–D discordance was very small in these years.

The mean error of the moon's tabular place (computed from Hansen's lunar tables with Newcomb's corrections) is $-0^{\mathrm{s}}\cdot099$ in R.A. and +0″·27 in N.P.D., deduced from 116 observations. These are equivalent to an error of −1″·38 in longitude and 0″·00 in ecliptic north polar distance.

The re-observation of the stars of Groombridge's Catalogue, which was the principal object of the Second Ten-Year Catalogue, furnishes material for determination of the proper motions of more than 4000 stars from observations about eighty years apart, with intermediate positions in the Radcliffe Catalogue of 1845. Provisional proper motions are given in the Introduction for 163 stars, for which the annual proper motion in R.A. or N.P.D. amounts to 0″·1 of a great circle, and had not previously been determined. It is proposed to undertake the determination of the proper motions of all the stars in Groombridge's Catalogue. Before doing this it was considered desirable to re-examine Groombridge's Observations, with special reference to the determination of azimuth error, in view of the large systematic error in Right Ascension. The original MSS. of Groombridge's Observations have been kindly lent by the Council of the Royal Astronomical Society, and the examination is in progress.

### The New Altazimuth.

This instrument is now in good working order. Various repairs have been required and minor improvements have been made. The observations of transits seem quite satisfactory, the accordance in the results for clock error in different positions of the instrument (referred to the transit circle) being very good. For the zenith distance observations further determinations of flexure and division-errors are required, and these are in hand. The investigation of the division errors of both circles has shown that the accordance of two determinations is not very satisfactory, and the cause of the discrepancy is now under investigation.

Among the observations made with this instrument may be mentioned 1729 R.A. observations of the sun, planets and stars, 1418 N.P.D. observations, and 2386 observations for collimation, level, and azimuth errors, and nadir.

### The 28-inch Refractor.

This instrument has been used throughout the year for micrometric measurements of double stars. 492 stars have been measured; 268 of these have their components less than 1″·0 apart, and 139 less than 0″·5. The stars whose distance apart is less than 1″·0 have been measured on the average on three nights each, and the wider pairs on two nights. The wider pairs measured consist of bright stars with a faint companion, of third companions to close pairs, and of stars of special interest.

In consequence of Mr. Newall's suggestion that the newly discovered spectroscopic binary Capella might possibly be observed as a double star with large telescopes, it has been examined on fifteen nights (from April 4 to May 10) by a number of observers, who all found the star's image to be sensibly elongated; while the position angle of the elongation changed during the period of observation (April 4 to May 29) in fair accordance with the period of 104 days given by Mr. Newall.

### Thompson Equatorial.

The 26-inch refractor has been in constant use throughout the year. The occulting shutter has been found of great value in obtaining accurately measurable photographs when one of the objects photographed is considerably brighter than the other objects in the field.

Fifteen photographs of Neptune and its satellite have been obtained, of which seven have been measured. Fifty-four photographs of twenty-six double stars have been obtained, of which forty-seven have been measured. Among these stars are Algol and Aldebaran, with their faint companions of fourteenth magnitude. The measures of distance and position-angle of the photographs of double stars are published in the *Monthly Notices of the Royal Astronomical Society* for April 1900. Nineteen photographs have been obtained of Comet Swift, of which fifteen have been measured, and the results published in the *Astronomische Nachrichten*, Nos. 3584–5. In addition, photographs of Polaris and neighbouring stars have been taken for parallax, a few photographs of the moon and some of the major planets with their satellites, and others for testing adjustments and the characters of the images in different parts of the field.

The 30-inch reflector has been used chiefly for the photography of nebulæ and star clusters. The photographs of the nebulosity of the Pleiades and of the Orion nebula are very fine, and show a large amount of detail.

### Astrographic Equatorial.

The following statement shows the progress made with the plates for the chart and the catalogue respectively:—

| | For the Chart (exposure 40m.). | For the Catalogue (exposures 6m., 3m., and 20s.). |
|---|---|---|
| Number of photographs taken ... | 243 | ... 236 |
| ,, successful plates ... | 162 | ... 181 |
| ,, fields photographed successfully ... | 155 | ... 175 |
| Total number of successful fields reported 1899 May 10 ... ... | 1027 | ... 1030 |
| Number of photographs, previously considered successful, rejected during the year ... ... ... | 106 | ... 102 |
| Total number of successful fields obtained to 1900 May 10 ... | 1076 | ... 1103 |
| Number still to be taken... ... | 73 | ... 46 |

A comparison of this list with the one published in the last report shows that great progress has been made in this work.

It is satisfactory to note that the plates are now placed in the new observatory, where they are kept dry and not subject to the extremes of temperature as formerly. Those that were previously spoilt through damp are now being gradually replaced.

During the year 88,000 measures of pairs of images (6m. and 3m.), as well as of the diameters of the 6m. images, have been made. The number of quarter plates measured in the twelve months in two positions of the plates is 556.

At the date of the last report the measurement of the plates was completed from December 64° to 69°; and in Zone 70° from R.A. oh. to 13h. 48m. During this year Zone 70° has been finished and Zones 71° and 72° have been measured, with the exception of thirty-six quarter plates. Subject to this exception, the measurement is complete from December 64° to 73°.

Good progress has been made with the printing of the measures. Zone 64° is finished and Zone 65° as far as R.A. 21h. 36m. It is estimated that all the measures from December 64° to December 72° will be included in one volume of about 650 pages.

### HELIOGRAPHIC OBSERVATIONS.

In the year ending 1900 May 10, photographs of the sun have been taken on 180 days, either with the Thompson or Dallmeyer photo-heliographs. The former, mounted on the Thompson 26-inch refractor, was used as the regular instrument for solar photography up to March 9, when it was temporarily dismounted, the Dallmeyer photo-heliograph being substituted for it. Of the photographs taken with either instrument, 369 have been selected for preservation, besides 11 photographs with double images of the sun, for determination of zero of position angle. Photographs to supplement the Greenwich series have been received from India or Mauritius up to 1900 March 8.

For the year 1899, Greenwich photographs have been selected for measurement on 202 days, and photographs from India and Mauritius (filling up gaps in the series) on 162 days, making a total of 364 days out of 365 on which photographs are at present available.

The chief characteristic of the sun's surface, during the period covered by this report, has been the steady decline in the mean daily number and area of spots observed, August and September 1899 in particular showing a marked sub-minimum.

### MAGNETIC OBSERVATIONS.

The variations of magnetic declination, horizontal force, and vertical force, and of earth currents have been registered photographically, and accompanying eye observations of absolute declination, horizontal force and dip have been made as in former years.

The regular observations of magnetic declination have been made since 1899 January 1, in the Magnetic Pavilion, alternating with determinations in the Magnet House (for effect of the iron in the Observatory buildings), the observations in the Magnetic Pavilion being made with a hollow cylindrical magnet mounted in conjunction with the large theodolite.

The determinations of horizontal force and dip have been made with the Gibson deflexion instrument and the Airy dip circle mounted in the new Magnetic Pavilion, since 1898 September.

The principal results for the magnetic elements for 1899 are as follows:—

| | |
|---|---|
| Mean declination ... ... ... | . . 16° 34′·2 West. |
| Mean horizontal force ... | 3·9947 (in British units).<br>1·8419 (in Metric units). |
| Mean dip (with 3-inch needles) ... ... | 67° 10′ 13″. |

These results depend on observations made in the new Magnetic Pavilion, and are free from any disturbing effect of iron. The correction to the declination, as found in the Magnet House, is − 10′·7, as deduced from the observations made with the new declinometer in the Magnetic Pavilion.

The magnetic disturbances in 1899 have been few in number. There were no days of great magnetic disturbance and sixteen of lesser disturbance. Tracings of the photographic curves for these days, selected in concert with M. Mascart, will be published in the annual volume as usual. The calculation of diurnal inequalities from five typical quiet days in each month has been continued.

The question of the regulations to be enforced for the protection of the Observatory from disturbance of the magnetic registers by electric railways or tramways in the neighbourhood is now under the consideration of the Board of Trade.

### METEOROLOGICAL OBSERVATIONS.

Consequent on the changes in connection with the new Observatory buildings, the shed containing the photographic thermometers was moved 15 feet towards the west on May 16 and 17, 1899.

The Kew Committee of the Royal Society has suggested that steps should be taken to assimilate the methods of registration of atmospheric electricity with the Thomson electrometers at Greenwich and Kew, and the question of the modifications to be introduced into the Greenwich electrometer is now under consideration.

The mean temperature for the year 1899 was 50°·7, being 1°·2 above the average for the fifty years, 1841–90.

During the twelve months ending 1900 April 30, the highest temperature in the shade (recorded on the open stand in the Magnetic Pavilion enclosure) was 90°·0, on August 15. The highest temperature recorded in the Stevenson screen in the Observatory grounds was 88°·8 on the same day.

The month of August was exceptionally warm, the mean temperature for the month being 65°·5, which is 3°·9 above the fifty years' average (1841–1890). This high temperature for the month has only been reached before on one occasion in the previous fifty-eight years, viz. in August 1857. The month of November was also exceptionally warm, the mean temperature for the month being 4°·8 above the average.

The lowest temperature of the air recorded in the year was 18°·0, on February 9. There were fifty days during the winter on which the temperature fell below 32°, a number slightly below the average.

The mean daily horizontal movement of the air in the twelve months ending 1900 April 30 was 268 miles, which is 13 miles below the average for the preceding thirty-two years. The greatest recorded daily movement was 776 miles on April 13, and the least 50 miles on October 22. The greatest recorded pressure of the wind was 27 lbs. on the square foot, on November 3, and the greatest hourly velocity 48 miles, on April 13.

The number of hours of bright sunshine recorded during the twelve months ending 1900 April 30, by the Campbell-Stokes instrument, was 1636 out of the 4454 hours during which the sun was above the horizon, so that the mean proportion of sunshine for the year was 0·367, constant sunshine being represented by 1.

The rainfall for the year ending 1900 April 30 was 21·97 inches, being 2·57 inches less than the average of fifty years. The number of rainy days was 146. The rainfall in the month of August was only 0·354 inch, being the smallest August rainfall on record in the fifty-nine years, 1841–99. The next smallest value was 0·45 inch, in August 1849. The rainfall in February amounted to 3·58 inches, being the largest February rainfall on record in the sixty years, 1841–1900, with the exception of the February rainfalls in 1866 and 1879, which amounted to 4·03 and 3·81 inches respectively.

The remaining portion of the report is devoted to the progress in the printing and distribution of the publications and chronometers, time-signals, longitude operations, &c.

In view of the large additions to and modifications in the instruments and buildings of the Royal Observatory in recent years, it is proposed to prepare a full description of the Observatory, illustrated by photographs.

It may be mentioned that the Observatory equipped and sent out an expedition to observe the total solar eclipse of May 28, having received the sanction of the Admiralty. The Astronomer Royal, with Mr. Dyson and Mr. Davidson, left for Ovar, in Portugal, on May 11, taking with them the Thompson 9-inch photographic telescope, the new 4-inch enlarging lens for large-scale photographs of the corona, a pair of photographic spectroscopes with heliostat, lent by Captain Hills, for photographing the spectrum of the lower chromosphere and of the corona, and a double camera, on one of the photo-heliograph mountings, with lenses of 4 inches and 2½ inches aperture for photographing the coronal streamers.

An examination of the fine photographs that were obtained by the party, which were shown on the day of the visitation, gave one a good idea of the success which had rewarded their efforts.

## THE GEOLOGICAL AGE OF THE EARTH.[1]

WHILE, in his efforts to arrive at an estimate of geological time, the geologist himself is seriously hampered by the uncertainty of the data at his disposal, he has followed with expectant interest the successive attempts made by votaries of

---

[1] "An Estimate of the Geological Age of the Earth." By J. Joly M.A., D.Sc., F.R.S., Hon. Sec. Royal Dublin Society; Professor of Geology and Mineralogy in the University of Dublin. Pp. 44. (*Scientific Transactions* of the Royal Dublin Society, vol. vii. Ser. ii. Dublin, 1899.)

kindred sciences to attain the solution of a problem so fascinating. It is true that past efforts in this direction have taught us to expect at the best a merely approximate result, by whatever method this problem may be attacked; at the same time, every attempt is welcome which shall tend to more narrowly limit the margin of approximation. In the important treatise before us, Prof. Joly proposes a novel and ingenious method of approaching this difficult question, and if his argument relies for its success on a considerable basis of assumption, he has nevertheless arrived at results of striking interest.

It is, first of all, assumed that the denudation by solution of the land surface, since the first formation of a solid earth-crust, has been on the whole a uniform process; and further, that the amount of sodium now contained in the ocean has been for the most part transported to it by rivers since the land surface first became exposed to the action of solvent denudation. The reasons which, in the author's view, render these assumptions probable truths are fully discussed in the paper. If, now, we can obtain a correct estimate of the amount of sodium at present contained in the waters of the ocean, and also of the amount annually supplied to the latter by rivers, we have the requisite data whereby the earth's geological age may be determined. Basing his calculations upon the most careful and recent estimates, Prof. Joly finds that the mass of sodium contained in the ocean amounts to 15,627 × $10^{12}$ tons. In estimating the amount of sodium carried annually by rivers into the sea, Sir John Murray's analyses of nineteen rivers (including many principal ones) are quoted, and a result of 24,106 tons of sodium per cubic mile of river water is obtained. Sir John Murray's estimate of the annual river discharge into the ocean, amounting to 6,524 cubic miles, is also accepted. From these figures the mass of sodium annually carried to the sea is calculated, and this amount divided into the total mass of sodium contained in the ocean, gives a result of about 94,800,000 years, representing the duration of geological denudation. So much is set forth in the first section of the paper. In the succeeding eight sections corrections on the above estimate are discussed, and several possible objections are dealt with.

The author first enters into a speculative discussion regarding the succession of events attendant on the first cooling of the earth's surface, with the object of arriving at conclusions as to the nature of the primitive ocean. Incidentally the view is favoured which supposes that at the first condensation of water upon the surface a greater density was conferred on the sub-oceanic crust than on the sub-aërial tracts; it is deemed improbable that this distribution of pressure became subsequently seriously modified, and the author gives his support to a belief in the permanency of ocean basins. The early ocean itself is supposed "for want of other known alternative," to have contained "a quantity of hydrochloric acid roughly represented by the chlorine now in the ocean." This being admitted, it is clear that a certain degree of saltness would primarily be acquired by the early hydrosphere, and this must be allowed for in modifying the above estimate of geological time. To accomplish this Prof. Joly first quotes Clarke's average analysis, showing the probable composition of the primitive earth-crust. The action of the heated acid ocean upon such a rock mass, and the apportioning of the acid among the bases, is next considered. It is calculated that of the total amount of chlorine contained in the original ocean, only 14 per cent. could have been taken up to form sodium chloride, and in order to arrive at the actual amount of this first formed sodium chloride, Prof. Joly proceeds to estimate the chlorine of the original ocean. This is done by subtracting from the total amount of chlorine now contained in the ocean the quantity of that element supposed to have been transported to it by rivers during the course of geological time. But of the river-transported chlorine a certain proportion has been derived from the sea itself, and for this a deductive allowance of 10 per cent. is made as probably sufficient. Having estimated that a total of about 76 × $10^6$ tons of chlorine are annually supplied by rivers to the sea, the author *assumes* the duration of geological denudation to have been about 86 × $10^6$ years, and finds that during this period 6536 × $10^{12}$ tons of chlorine have been introduced into the ocean. By subtracting this from the total chlorine now contained in the sea (as sodium chloride and magnesium chloride), a total of 21,780 × $10^{12}$ tons is arrived at, representing the original chlorine of the oceanic waters. If 14 per cent. of this would unite with sodium, then 1972 × $10^{12}$ tons of sodium were brought into solution by the action of the primitive acid ocean. This result can now be employed in correcting the original estimate of geological time, which was reckoned on the supposition that all the sodium now in the ocean had been supplied by rivers. Thus, the total amount of sodium supplied by rivers is reduced to 13,655 × $10^{12}$ tons, and this deductive correction of 12·6 per cent. reduces the duration of geological time to 86·9 × $10^6$ years. The value of this ingenious correction appears to be lessened, however, by the necessary introduction of an arbitrary assumption for the duration of geological time. Is there any reason, too, to show that at the first condensation of water upon the earth, alkalies may not have been present to neutralise to almost any unknown extent the acid of the primæval ocean? The author believes that the amount of correction necessary in allowing for the action of acids other than hydrochloric, in the primitive ocean, is practically negligible.

By a further slight modification of the figures representing the sodium annually transported into the sea, a final estimate of 89·3,000,000 years is arrived at, a figure based, we are told, "on the most complete estimate of probabilities." But even in this estimate the author does not claim a degree of accuracy "approximating to so small a time interval as 100,000 years."

Prof. Joly then examines the significance of rock-salt deposits, as possessing a possible bearing on his theory, but having discussed the origin of such deposits he concludes that any error involved by ignoring them must be very slight. But the extent of the saline deposits surely cannot possibly be estimated, and may perhaps have been considerably underrated. Even if it be admitted, as urged by the author, that the salt basins of the present day are in great part not of oceanic origin, this does not necessarily apply in like degree to saline deposits of the past, when earth movements may have played a more vigorous part in aiding their formation as oceanic derivatives.

A point of seemingly great significance in its bearing on Prof. Joly's theory is the retention of salts in the interstices of stratified rocks, the salts derived from the waters in which the rocks were laid down. In 1856 Dr. Sorby drew attention to the soluble salts contained in certain dolomites, and Dr. Sterry Hunt has recently referred to the "fossil sea water" retained in the pores of stratified rocks.

The observations of the Rev. O. Fisher on this point, recorded in a recent review of Prof. Joly's paper (*Geol. Mag.*, March 1900) are of the greatest interest, as showing that some of the sodium of river waters may have been derived not from the rocks, but originally from the ocean itself.[1] In estimating the mass of sodium held in solution by the ocean, should not some allowance be made too for an unknown bulk of highly pervious deep-sea sediments? May not such deposits be in part of great thickness, and by reason of the sea water with which they are impregnated form a store for sodium?

In the succeeding section the potash and soda percentages of the igneous and sedimentary rocks respectively are considered. Quoting Clarke and Rosenbusch for estimates of these, Prof. Joly attempts to prove that the deficiency of soda in the sedimentary rocks (1·47 per cent. of soda and 2·49 per cent. of potash, as against 3·61 per cent. of soda and 2·83 per. cent. of potash in the primitive crust) is accounted for by the amount of sodium calculated to have been supplied to the ocean by rivers. It is claimed "that the estimated amount of sedimentary strata would, in its formation, be adequate to yield to the ocean the sodium that is in it, assuming these sedimentaries to be derived from rocks having the mean composition of the important eruptive masses now known." Allowance is made for a slight deficiency in the sodium of the ocean by the existence of the rock-salt deposits. For the success of this argument it is unfortunately necessary to assume that a correct estimate of the total bulk of the sedimentary rocks is possible. Mr. Mellard Reade's calculation is provisionally taken as a basis. Accepting also Mr. Reade's estimate of the proportion of calcareous to other sediments, the latter are found to be equal to a layer 1·6 miles in depth over all the land area. From this the mass of the detrital sediments is calculated, and the actual amount of their soda is arrived at. To this is now added the amount of sodium (reckoned as soda) contained in the sea. This restoration would bring the soda percentage of the total mass of sedimentary rocks, even allowing for the rock-salt deposits, to little above 3 per cent., and in order that the figures shall be brought into better accordance with Clarke's calculated soda percentage for the primitive crust, the estimate of the amount of detrital sedimentary rocks is ingeniously amended to equal a layer 1·1 miles thick over all the land area, with the result that an amount is obtained little short of the desired 3·61. This result must appear sufficiently striking, but it may be seriously doubted whether even an approximate estimate of the total bulk of sedimentary strata can possibly be arrived at. Such an estimate must inevitably rest in great part on a basis of pure speculation. Not only are we ignorant, as regards huge areas, of the thickness of these strata, but immense tracts still remain unexplored so far as their geology is concerned. Further, the boldest guess can tell us little of sedimentary strata hidden beneath the surface of the ocean, and it may be looked upon as a lucky coincidence that Prof. Joly is able to attain the above result when restoring to the estimated sedimentary rocks the sodium of the sea. The question also of pre-Cambrian rocks of sedimentary origin appears here to be too lightly passed over, for although so little is known of their actual extent, the trend of recent researches has been to show that they may constitute a not unimportant fraction of the total sediments formed. It is scarcely necessary to recall the fact that the earliest known fossil faunas, including marine forms of comparatively high organisation, clearly indicate that a habitable ocean had already for long ages been in existence.

---

[1] Since these lines were written. Prof. Joly has dealt further with this point and with the question of alkalies neutralising the primitive acid ocean (*Geol. Mag.*, May 1900).

The unequal ratios of the alkalies in the ocean and in the rivers respectively next receive attention. The fact that the ratio of potash to soda is very much higher in the rivers than in the sea, is believed by the author, not to indicate that the rivers now contain more potash relatively to soda than in former times, but is to be accounted for by the constant abstraction of potash from the ocean, largely in the glauconite now forming on the sea floor, and so extensively distributed in the sedimentary strata. Stress is also laid on the fact that potassium brought from the atmosphere by rain tends to become retained upon the land, while the sodium is more readily returned to the ocean. In arguing for the uniformity of denudation by solution in past times, Prof. Joly brings forward some good reasons to show that the distribution of land and sea can have varied but little. As regards the greater exposure of igneous rocks in early times some interesting points on the nature of weathering and soil formation are noted, and it is concluded that the unequal percentage of sodium in the igneous and sedimentary rocks would, as regards supply to the ocean, be counterbalanced by the different rates of weathering. Sedimentary rocks, poorer in alkalies, allow of more rapid denudation.

In the concluding section of this paper the action of the ocean as an agent in solvent denudation is dealt with. Such action, the author maintains, is carried on chiefly along the coast lines, and is very small as compared with that effected by rain and river waters. Experiments are quoted to show that the power of sea-water to decompose felspar is minute in comparison with that exerted by fresh water. It is further pointed out that the volcanic *débris* of oceanic deposits have the alkali ratio of igneous and not that of sedimentary rocks. A correction of half a million years on the original time estimate is thought to be a sufficient allowance to make for the solvent denudation by the ocean. But even allowing, as held by the author, that chlorides other than sodium chloride may in past times have in some measure retarded solvent denudation by the ocean, it may be suggested that subaqueous volcanic action, at one time more frequent than at present, with its attendant conditions of exceptional temperature and pressure, may by frequent repetition through vast periods of time have played some part in aiding this process.

Prof. Joly does well in finally recognising the uncertainty attending his corrections on the original estimate of geological time, and he certainly allows no too wide a margin for error in the final result when he claims that "a period of between eighty and ninety millions of years" has elapsed since the land first became exposed to denuding agencies. For not only in the data upon which the corrections are founded, but also in the factors employed in the original calculation, there is to be found comparatively little of certainty and much that is purely speculative. In this latter category must be placed the supposed sequence of events at the first cooling of the globe. The relative intensity of geological activities in the past is also unknown to us, and the possibilities as regards the activity of the sun and the influence of the moon in modifying meteorological agencies during the earlier chapters of the earth's history appear to render hopeless the final solution of the time-problem by such a method as that here employed. But in this interesting treatise Prof. Joly has with marked ability and originality attacked a most difficult question, and his novel theory calls for the fullest consideration from all geologists and physicists.

## NOTES ON SATURN AND HIS MARKINGS.

THE possessors of telescopes will welcome the reappearance of Saturn as a rather conspicuous object in the evening sky. The planet now rises at 7h. 40m. p.m., and remains visible afterwards throughout the night, but unfortunately his altitude is extremely low. His southern declination being 22½°, his position is only 16° above the horizon at Greenwich even at the time of his meridian passage. Notwithstanding these unfavourable conditions, excellent views may, however, occasionally be obtained of his general aspect. From stations in the southern hemisphere the planet may be seen under the best circumstances.

This planet with his rings, belts and moons, forms a picture quite unique of its kind. The globe is greatly compressed at the poles, like that of Jupiter, and the rate of its axial rotation similarly rapid. We recognise also in the dusky bands of Saturn another parallel to the visible lineaments of the "Giant Planet," but there is a marked difference as regards the distinctness with which the details on the two bodies may be viewed. Jupiter's large disc and superior brilliancy enable the markings and their variations of form and motion to be followed with great facility and certainty. Saturn being much smaller and fainter is more difficult, especially as regards the more delicate features. Cassini's division in the rings and the principal belt on the globe may be distinguished with a two inch refractor, but Encke's division in the outer ring is a doubtful, or probably a very variable feature, which at certain times appears to be missing altogether, while on other occasions it is described as faintly outlined as a pencil-like curve at the ansæ.

That there are occasional irregularities on Saturn is proved beyond contention. In 1790 Sir W. Herschel remarked a very dark spot on the limb, and in 1793 noticed some irregularities in a quintuple belt which enabled him to ascertain the planet's rotation period. The large white spot seen by Prof. Hall and others at the close of 1876 affords a good instance of change, and it is well-known that the disposition and number of the belts vary from year to year. We naturally conclude that these belts must occasionally exhibit irregularities like those of Jupiter.

The planet is now presented to us at an angle which permits the ring system to be seen with splendid effect. We now view the northern side of the ball and rings, and this will continue to be the case until 1907.

Perhaps there is no object upon which it is easier to exercise the imagination than upon Saturn. And there is probably no orb in reference to which more errors in detail have been made, though both Mars and Venus have encouraged a large number of observational misconceptions. Many of the abnormal results reported in recent years, and due to small instruments, may be safely dismissed, for they are not only doubtful but, when all the conditions are considered, ridiculous, and palpably the outcome of unconscious suggestions of the imagination. Yet there can be no question as to the good faith of those who are responsible for some of the wonderful seeings lately published. They honestly believe they have seen what they have drawn, and as a matter of fact it is an extremely difficult point to distinguish between real and imaginative features on Saturn. The trembling of the image, its faintness under high power or its smallness under low power encourage much fictitious detail which every observer cannot regard as illusory.

Some of those who claim to have seen many irregular markings on this beautiful planet ascribe their success to special training; but this explanation will scarcely stand, for others of equal experience and using more powerful appliances have quite failed to observe them. The difference is not one of sight, of practice, or of instrumental means. It resolves itself into a question of personal ethics. There are men who will report nothing but what they are absolutely certain is presented to their eyes, and are unbending in their regard for the truth; there are others who, though equally sincere in intention, are not so reliable in their judgment, and accept features which are apparently glimpsed, but which are in reality prompted by the imagination on an unsteady and very delicate object.

It is to be hoped that time will eliminate all the fanciful representations of Saturn which recent observations have so abundantly supplied. The period has now arrived when the planet may be telescopically surveyed with a view to obtain a really sound knowledge of such features as are portrayed in moderately powerful instruments. Those who have employed large and small telescopes in planetary observation aver that the former are more effective than the latter; but it is remarkable that small instruments have been the means by which a large amount of useful work has been done in this field of observation. It is also an unavoidable conclusion that many of the mistakes in planetary work have been due to inadequate power and light in the appliances used. Possibly during the next few months some of the existing discordances may be cleared up, and some new facts learnt concerning this the most beautiful planet of our system.

There was an interesting occultation of Saturn by the moon on June 13, but at Bristol clouds interfered with observation. At Yeovil, Somerset, the Rev. T. E. R. Phillips watched the phenomenon with a 3-inch refractor. There will occur another event of this kind on September 3 next, when the planet will disappear at 7h. 16m. and reappear at 8h. 11m. p.m. Occultations of Saturn are somewhat rare, the last, prior to that of June 13, occurring twelve years ago, viz. on October 1, 1888.

The planet may now be studied with advantage from southern observatories, where his altitude will be considerable and conduce to that excellent definition which is so necessary for the detection of faint and delicate markings. At every opposition it seems necessary that the number and arrangement of the various belts should be noted. A dark polar cap should be looked for, and any irregular appearances, such as dark and light spots on the dusky belts or intervening zones, should be carefully recorded. It is unfortunate that the results obtained in previous years are not sufficiently accordant to be of much service. In some cases where one observer has drawn one or two belts, another, equally experienced and with more powerful means, has represented seven or eight. Certain observers see the belts and zones mottled with spots, while others describe the aspect as perfectly smooth and quite devoid of all such irregularities. The evidence is, in fact, so conflicting that new and thoroughly trustworthy observations are greatly needed to set at rest the actual character of the details visible on this exceedingly attractive object.

W. F. DENNING.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—On April 27, 1899, an anonymous gift of 5000*l*. was made towards the building of a pathological laboratory. The donor now allows his name to be made known, and a decree will consequently be proposed on July 7, that the thanks of the University be conveyed to Ewan Richards Frazer, B.M., Balliol College, for his munificent donation to the pathological laboratory.

CAMBRIDGE.—The annual report of the Cambridge Observatory appears in the *Reporter* for June 30. It includes an account of valuable work done with the Newall telescope, and of the steps taken to bring to perfection the Sheepshanks photographic equatorial. The binary character of $\alpha$ Aurigæ was announced as discovered at the Observatory two days before the arrival of Prof. Campbell's independent publication from the Lick Observatory.

Scholarships, or exhibitions, in natural science have been awarded at the following Colleges thus:

Peterhouse: Lee.

Gonville and Caius: Cleminson, Burne, Garnsey, Lock, Macfie, Rittenberg, Thornton.

The Hopkins Prize for the period 1894–97 has been awarded to Mr. J. Larmor, F.R.S., of St. John's College, for his investigations on the Physics of the Aether and other valuable contributions to mathematical physics.

Mr. William Ritchie Sorley, formerly Fellow of Trinity College, has been chosen Knightsbridge Professor of Moral Philosophy in the place of Dr. Henry Sidgwick, who has resigned in consequence of ill health.

PROF. SIMON NEWCOMB has had the degree of doctor of laws conferred upon him by the University of Toronto.

PROF. J. H. POYNTING, F.R.S., has been elected Dean of the Faculty of Science of the University of Birmingham.

THE honour of knighthood has been bestowed upon Dr. G. Hare Philipson, president of the University of Durham College of Medicine, Newcastle-upon-Tyne.

PROF. J. R. CAMPBELL, head of the Agricultural Department of Yorkshire College, has been appointed under-secretary to the Department of Agriculture and Technical Instruction for Ireland.

THE honorary degree of D.Sc. has been conferred by the University of Oxford upon Prof. J. Mark Baldwin, of Princeton University, New Jersey, U.S.A. The new doctor is professor of psychology at Princeton, and editor of the *Psychological Review*.

HONORARY degrees were on Saturday last conferred by the Victoria University upon Lord Rayleigh, Sir William Huggins, Sir W. C. Roberts-Austen, Sir William Abney, Dr. T. E. Thorpe, Prof. J. Dewar, Prof. A. R. Forsyth, Mr. R. T. Glazebrook, Prof. Pickering, Prof. J. J. Thomson, and Mr. Henry Wilde.

A GRANT of 58*l*. from the Earl of Moray Endowment has been made by the Edinburgh University Court to Dr. J. H. Milroy for purposes of research. At a recent meeting of the Court it was announced that the late Prof. Sir D. Maclagan had bequeathed a marble bust of himself to the University, and that Miss E. A. Ormerod had presented six large volumes of drawings, chiefly by her father, to the library.

THE Drapers' Company offer for competition eight scholarships tenable at the day classes of the East London Technical College in chemistry, physics and engineering. The scholarships are of the value of 25*l*., 10*l*. being paid during the first year and 15*l*. during the second year. They also carry with them free tuition. Particulars may be obtained from the Director of Studies, East London Technical College, People's Palace, E

THE annual meeting terminating the session of the department of engineering in connection with University College, Liverpool, took place on Thursday last, when the William Rathbone Medal and the Rathbone Prizes were distributed by the Lord Mayor of Liverpool. The report, which was of a highly satisfactory character, was read by Prof. Hele-Shaw, after which an address was delivered by Prof. John Perry, F.R.S., upon the value of a thorough scientific education to the engineer.

THE following is a list of the members of the new Board of Education Consultative Committee:—Rt. Hon. Arthur Herbert Dyke Acland, Sir William Reynell Anson, Bart., M.P., Prof. Henry Armstrong, Mrs. Sophie Bryant, Rt. Hon. Sir William Hart Dyke, Bart., M.P., Sir Michael Foster, K.C.B., M.P., Mr. James Gow, Litt.D., Mr. Ernest Gray, M.P., Mr. Henry Hobhouse, M.P., Mr. Arthur Charles Humphreys-Owen, M.P., Sir Richard Claverhouse Jebb, M.P., Hon. and Rev. Edward Lyttelton, Very Rev. Edward Craig Maclure, D.D., Dean of Manchester, Miss Lydia Manley, the Venerable Ernest Grey Sandford, Archdeacon of Exeter, Mrs. Eleanor Mildred Sidgwick, Prof. Bertram Coghill Alan Windle, M.D., Rev. David James Waller, D.D. The draft Order in Council, giving particulars of the duties, &c., of the Committee, has been issued as a Parliamentary paper.

FURTHER munificent gifts for the furtherance of education in the United States are announced in *Science* and are as follows:—The sum of 125,000 dollars has been left to Harvard University by the late Edmund Dwight. The bequest will come into the hands of the University authorities after the death of certain persons who receive the income during their lifetime. The amount (100,000 dollars) promised by Mr. Rockefeller to Denison University, on condition that 150,000 dollars additional be raised before July, has now been claimed, the sum named having been subscribed. The sum of 50,000 dollars has been given to Colorado College by Mr. W. S. Stratton; Mr. M. K. Jesup has given 25,000 dollars to Princeton University, and Lombard College in Galesburg, Ill., benefits in a like degree by the gift of Mr. W. G. Waterman; while 10,000 dollars have been subscribed by Messrs. Phelps, Dodge and Co. for the endowment of the department of mining and metallurgy at Columbia University. In addition to the foregoing it is announced that Mr. L. C. Smith will build and equip a civil engineering building in connection with Syracuse University.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, June 14.—"The Nature and Origin of the Poison of *Lotus Arabicus*." By Wyndham R. Dunstan, F.R.S., Sec.C.S., Director of the Scientific Department of the Imperial Institute, and T. A. Henry, B.Sc.Lond.

*Lotus Arabicus* is a small leguminous plant resembling a vetch, indigenous to Egypt and Northern Africa. It grows abundantly in Nubia, and is especially noticeable in the bed of the Nile from

Luxor to Wady Halfa. It is known to the natives as "Khuther," and old plants with ripe seed are used as fodder. The dried plant is unusually green, and possesses the aroma of new-mown hay. At certain stages of its growth it is highly poisonous to horses, sheep and goats, the poisonous property being most marked in the young plant up to the period of seeding. Owing to the trouble which this plant has given to the military and civil authorities in Egypt, the assistance of the Director of Kew was sought in order that the precise nature of the poison might be ascertained, and, if possible, a remedy found. The matter having been referred to the Scientific Department of the Imperial Institute, Mr. E. A. Floyer, Director of Egyptian Telegraphs, collected some of the material for investigation.

It was found that when moistened with water and crushed, the leaves of the plant evolved prussic acid in considerable quantity, the amount being greatest in the plant just before and least just after the flowering period. Further investigation has shown that the prussic acid originates with a yellow crystalline glucoside ($C_{22}H_{19}NO_{10}$), which it is proposed to name *lotusin*. Under the influence of an enzyme, also contained in the plant, lotusin is rapidly hydrolysed, forming *prussic acid*, *sugar*, and a new yellow colouring matter (*lotoflavin*). The hydrolysis may be effected by dilute acids, but is only very slowly brought about by emulsin and not at all by diastase. The peculiar enzyme, which it is proposed to call *lotase*, appears to be distinct from the enzymes already known. Its activity is rapidly abolished by contact with alcohol, and it has only a feeble action on amygdalin. Old plants are found to contain lotase but no lotusin.

The *sugar* has been proved to be identical with ordinary dextrose.

*Lotoflavin*, the yellow colouring matter, has the composition expressed by the formula $C_{15}H_{10}O_6$. It belongs to the class of phenylated pheno-γ-pyrones, and is a dihydroxychrysin, isomeric with luteolin, the yellow colouring matter of *Reseda luteola*, and with fisetin the yellow colouring matter of *Rhus cotinus*.

The decomposition which ensues on bringing lotase in contact with lotusin, as happens when the plant is crushed with water, is therefore probably expressed by the following equation:—

$$\underset{\text{Lotusin.}}{C_{22}H_{19}NO_{10}} + 2H_2O = \underset{\text{Lotoflavin.}}{C_{15}H_{10}O_6} + \underset{\text{Prussic acid.}}{HCN} + \underset{\text{Dextrose.}}{C_6H_{12}O_6}.$$

Hydrocyanic (prussic) acid occurs in small quantity in many plants, and according to Treub and Greshof is often present in the free state. The only glucoside at present definitely known which furnishes this acid is the well-known amygdalin of bitter almonds, which under the influence of the enzyme emulsin, also contained in the almond, breaks up into dextrose, benzaldehyde and prussic acid.

Owing to the scientific interest which attaches to this new glucoside, its properties and those of its decomposition products have been very fully studied, and the characteristics of the new enzyme have also been investigated.

We are much indebted to Mr. Floyer for the great pains he has taken to collect, in Nubia, the necessary material for this investigation, and also to Sir W. T. Thiselton-Dyer for having grown the plant at Kew from seed obtained from Egypt.

"The Exact Histological Localisation of the Visual Area of the Human Cerebral Cortex." By Joseph Shaw Bolton, B.Sc., M.D., B.S. (Lond.).

**Geological Society**, June 6.—J. J. H. Teall, F.R.S., President, in the chair.—Mechanically-formed limestones from Junagadh and other localites, by Dr. J. W. Evans. After reviewing the conditions under which granular limestones may be accumulated by current- or wind-action, the author proceeds to describe the limestone of Junagadh, a deposit some 200 feet thick, resembling in hand-specimens the Oolites of this country, though less firmly cemented together. The deposit is situate at a distance of thirty miles from the sea, and contains no large fossils of any kind. Calcareous rocks of similar character are described from other parts of Kathiawad, Kach, the south-eastern coast of Arabia, and the Persian Gulf—some of these contain unbroken marine shells and other fossils. These beds are included by Dr. H. J. Carter under the name of miliolite, on account of the frequent presence in them of the genus *Miliola*. The author discusses the origin of these deposits, and comes to the conclusion that the grains were formed in sea-water saturated with carbonate of lime: some being deposited by currents in shallow water, and others thrown up as a calcareous beach, from which a portion were sifted out by the wind and blown inland to form æolian deposits.—Note on the consolidated æolian sands of Kathiawad, by Frederick Chapman. The name miliolite-formation was originally given by Dr. H. J. Carter to certain granular calcareous deposits occurring on the coast-line between the peninsula of India and the mouth of the Indus. The foraminifera and other organic remains in the rocks must have inhabited moderately shallow to littoral marine areas. The minute granules are worn and polished; the prevailing genera of foraminifera are roundish, and would be easily moved by wind; remains of larger organisms are absent; and the deposits are false-bedded. All these phenomena are explicable if the deposits represent the accumulation of material derived from littoral calcareous sand of marine origin, mixed with mineral detritus from adjacent hills.—On Ceylon rocks and graphite, by A. K. Coomara Swamy. Ceylon is surrounded by raised beaches, and has been elevated in recent geological times; fluviatile deposits also occur: the gems for which Ceylon is famous are obtained from gravels in the Ratnapura district. With the exception of these recent deposits, the island probably consists entirely of ancient crystalline rocks. Graphite occurs chiefly in branching veins in igneous rocks, which at Ragedara are granulites and pyroxene-granulites. The relations to the matrix are described, and are held to favour the idea of the deposition of the mineral as a sublimation-product (Walther), or from the decomposition of liquid hydrocarbons (Diersche). Analysis of several of the minerals, including manganhedenbergite, are given; and a bibliography of the geology of the island is appended.

**Mineralogical Society**, June 19.—Prof. N. S. Maskelyne, F.R.S., Past-President, in the chair.—Prof. H. A. Miers presented a communication from Miss Agnes Kelly on conchite, a new form of calcium carbonate. Conchite forms the material of various calcareous secretions in the animal kingdom (more particularly molluscan shells) which have hitherto been referred to aragonite; it also occurs as the fur in kettles and boilers, and in many concretionary deposits, such as those of Karlsbad. In most of its characters it is intermediate between calcite and aragonite; like calcite it is uniaxial negative, but shows no cleavage or twinning, and has higher indices of refraction; and like aragonite it is converted into calcite on heating, but the change takes place at a lower temperature.—Mr. G. F. Herbert Smith described a method for the determination of the three principal indices of refraction from observations made in any arbitrary zone. This method is intended for minerals of low symmetry of which the indices are higher than those of any liquid. Observations are made of the deviations corresponding to different angles of incidence on both faces of a prism, and curves connecting the indices and the angles of orientation are plotted out. As in the method of total reflection, three of the critical values give the principal indices.—Mr. H. L. Bowman described the occurrence of monazite at Tintagel, and gave a detailed account of the crystallographic characters of the associated minerals, albite, quartz, rutile, pyrites and calcite.—Dr J. W. Evans discussed the alteration of pyrites by underground water, a question which had arisen in connection with the erection of a dam in Mysore. From his experiments the author concludes that, provided the water contain a sufficient amount of carbonate of lime to neutralise the sulphuric acid resulting from the oxidation of the pyrites, exact pseudomorphs of limonite after pyrites are formed; and as these occupy practically the same volume as the original pyrites, the rock suffers little disintegration by the action of the water.—Petrological notes by Mr. G. T. Prior dealt with the so-called "cancrinite-ægyrine-syenite" of Elfdalen, which he refers to sussexite at the basic end of the grorudite-tinguaite series of Brögger; with a riebeckite-ægyrine-tinguaite (so-called "proterobase") from the Rupbachthal; and with melilite-basalts from Madagascar and Siam.—Mr. L. Fletcher discussed the quantitative determination of the action of hydrochloric acid and of soda-solution on the enstatite and felspar of the Mount Zomba meteorite.

### CAMBRIDGE.

**Philosophical Society**, May 21.—Mr. J. Larmor, President, in the chair.—On a certain diophantine inequality, by Major MacMahon, R.A., F.R.S.—On rational space curves of the fourth order, by Mr. Richmond.—On the reduction of quadrics, by Mr. Bromwich.—Experiments upon the rise of temperature of fabrics when moistened, by Dr. L. Cobbett. Dr. Cobbett showed that if expired air is breathed through several layers of dried filter paper wrapped round the bulb of a thermometer, a temperature of 10° C. or more above that of the body may be registered (Dr. Dudgeon's experiment); and that if a roll of flannel, thoroughly dried, be warmed to 96° C. and put into saturated steam at 100° C., the temperature within the roll may rise 30° C. or more above that of the steam (Dr. Parson's experiment). Further, he showed that when a roll of flannel, which has not been artificially dried is put into steam, at atmospheric pressure, heated to 200° C., though the surface of the roll becomes charred, the temperature in its interior rises rapidly to 100° C., but does not exceed this for a long time—indeed, not until all the separable water has been boiled away. He concluded that such substances when quite dry have the property of uniting with water, and of generating heat in the process, and this without becoming damp in the ordinary sense of the word; and maintained that the source of this heat is not alone the latent heat of the vapour condensed, because a rise of temperature takes place when dried filter paper is wetted with water at the same temperature, but must include also either the latent heat of water converted into the solid state—as Sir W. Roberts has suggested in discussing Dr. Dudgeon's experiment—or else the energy set free in a chemical combination between the material and the water.—Experiments upon striated discharges, by R. S. Willows. The conditions affecting the distance between the striæ were investigated for hydrogen, nitrogen and air. In the first gas, as the current was increased from a very small value, the striæ first separated, attained a maximum distance of separation, and finally approached each other. In nitrogen and air their distance apart at first increased, and finally became constant. The distance apart varies inversely as the pressure until the discharge reaches the walls of the tube. The effect of the nature of the gas, the diameter and length of the tube, and the shape of the electrodes was also investigated. Any variation due to these was found to obey no simple law. The double striæ in hydrogen, noticed by De la Rue and Müller, were found to constitute a normal part of the discharge in this gas, provided a suitable pressure were established.—A method of measuring the retardation produced by a crystal plate, by L. R. Wilberforce. The author described a ready way of approximately determining the retardation produced by a plate of biaxial crystal cut perpendicularly to a mean line. The requisite measurements could be made with an ordinary polariscope.

### PARIS.

**Academy of Sciences**, June 25.—M. Maurice Lévy in the chair.—Problem of the cooling of a wall by radiation, reduced to the simpler case of cooling by contact, by M. J. Boussinesq.—Note on a series of abnormal contacts in the western region of the lower Pyrenees, by MM. Michel-Lévy and Léon Bertrand.—M. Giard was elected a member of the Section of Anatomy and Zoology in the place of the late M. Milne-Edwards, and M. Bazin was elected correspondent for the Section of Mechanics.—On the large sun-spot observed on June 17 with the great telescope of 1900, by M. Moreux. This sun-spot, a drawing of which accompanies the note, had a diameter of 36,000 kilometres, and furnished a good example of the mechanism of segmentation of a sun spot. According to the author's hypothesis, the phenomena are not due to cyclones or volcanoes, but to superheated regions.—Trigonal normal curves, by M. F. Amodeo.—On the motion of a wire in space, by M. G. Floquet.—On two remarkable groups of geometrical loci, by M. E. Mathias. In his experimental results obtained with carbonic acid, M. Amagat has considered the case of the locus of points in the $(p, v)$ plane, such that for a total weight of liquid and vapour equal to unity, the volume of the liquid is constantly equal to that of the vapour. This locus, according to M. Amagat, is a straight line, nearly perpendicular to the axis of abscissæ; but the author now shows that this locus is a curve constantly convex towards the volume axis.—On the discontinuity of the kathodic emission, by M. P. Villard. The three modes of exciting a Crookes' tube are considered, alternating currents, an induction coil and a static machine, and in each the phenomenon would appear to be discontinuous.—On the permeability of fused silica to hydrogen, by M. P. Villard. At 1000° fused quartz resembles platinum, in allowing hydrogen to pass through.—On the resistance of fused silica to sudden variations of temperature, by M. Dufour.—On the telegraphone, by M. Valdemar Poulsen. A description of an instrument for automatically recording words spoken through a telephone.—On the development and propagation of the explosive wave, by M. H. Le Chatelier. An application of the photographic method to the study of the explosive wave. Measurements are given for various mixtures of acetylene and oxygen, acetylene and nitric oxide, acetylene and nitrous oxide, and carbon monoxide and oxygen. In the last case the velocities depend upon the mode of ignition, and upon the quantity of the fulminating substance used to start the explosive wave.—On the acidity of the alcohols, by M. de Forcrand. A thermochemical paper.—Addition of hydrogen to ethylene in presence of various reduced metals, by MM. Paul Sabatier and T. B. Senderens. Reduced cobalt effects the combination of ethylene and hydrogen at ordinary temperatures similarly to reduced nickel. A comparison of the results obtained with reduced nickel, cobalt, copper and iron shows that the activity of the metals in causing this reaction is in the order given, nickel being the most energetic.—On the crystalline combinations of acetylene with cuprous chloride and potassium chloride, by M. Chavastilon. It has been previously shown by the author that two kinds of crystals, yellow and colourless, may be obtained from the same copper solution, according to the velocity of the current of acetylene. Further analyses show that the colourless crystals correspond to the formula

$$C_2H_2.(Cu_2Cl_2)KCl,$$

and the yellow crystals,

$$C_2H_2.[(Cu_2Cl_2)_2KCl.]_2.$$

By the action of ether upon the colourless compound, the yellow crystals are obtained.—Oxidation of anethol and analogous substances containing a lateral propenylic chain, by M. J. Bougault. The method of oxidation used is the action of iodine in presence of precipitated mercuric oxide, an aldehyde being obtained. Aldehydes from anethol, isosafrol, isomethyleugenol and isoapiol have been prepared, together with the corresponding acids.—On a new derivative of benzophenone, by MM. Œchsner de Coninck and Derrien.—Composition of the compounds of fuchsine with acid colouring matters, by M. A. Seyewetz.—On the kidney of *Lepadogaster Goüanii*, by M. Frédéric Guitel.—On a fayalite rock, by M. A. Lacroix. The fayalite of Callobrières presents a very remarkable and exceptional mineralogical composition. It is essentially characterised by the association of the fayalite with grünerite, apatite and magnetite.—The function of the cell nucleus in absorption, by M. Henri Stassano. The nucleus, by reason of its chemical composition, plays a predominating part in the absorption of foreign substances.—On the proteolytic diastase of malt, by MM. A. Fernbach and L. Hubert.—Action of high frequency currents upon the elementary respiration, by M. Tripet. In diseases of nutrition, treatment by high frequency currents regulates the activity of reduction of the oxyhæmoglobin.—Influence of extracts of the ovaries upon the modifications of nutrition caused by pregnancy, by MM. Charrin and Guillemonat.—The lake of Ladoga from the thermal point of view, by M. Jùles de Schokalsky.—On a balloon ascent made on June 17, by M. Genty.—On an extraordinary halo observed on June 22, by M. Joseph Jaubert.

THURSDAY, JULY 12, 1900.

## A MONOGRAPH ON LAND-PLANARIANS.

*Monographie der Turbellarien.* II. *Tricladida Terricola* (*Landplanarien*). By Prof. Ludwig von Graff. Pp. i + 574, and an atlas of 58 plates. (Leipzig: W. Engelmann, 1899.)

THE Turbellaria are rapidly becoming one of the most adequately and conveniently described groups of Invertebrates. Practically all that is at present known as to their anatomy, classification and distribution is comprised in three works—the "Monograph," by Prof. von Graff; the special memoir, by the same author, on the "Acœla"; and the masterly work, by Prof. Arnold Lang, on the "Polycladida" in the series of monographs on the fauna and flora of Naples Bay. The work before us, a magnificent folio, completes the author's share in the monographic treatment of the group. The first part was published in 1882, and was reviewed in this journal by Prof. Moseley. It is with great pleasure that we notice the dedication of the second part—jointly to Moseley and Fritz Müller—as only one of the many felicitous ways in which Prof. von Graff expresses his admiration for the work of these his fellow-labourers in the anatomy of planarians. We heartily congratulate Prof. von Graff on the appearance of this volume, the conclusion of a work begun twenty-five years ago.

Apart from all other claims upon our notice, this treatise is remarkable as being the first attempt to deal exhaustively with an essentially tropical group of animals, for nothing can be clearer, after reading this account, than that land-planarians, though not restricted to the tropics, have their headquarters in the equatorial forest belt. Von Graff has himself spent some time in Java, Singapore and Ceylon, and the personal acquaintance made in this way with these animals, and the conditions under which they live, gives a vividness and directness to his descriptions. Other naturalists have notably assisted him. Prof. Dendy, whose admirable and continued researches on the land-planarians of Australia and New Zealand receive full acknowledgment in this work, Spencer, Hamilton, Fletcher and others have sent collections of these animals to von Graff from Australia. Strübell, Max Weber, the Sarasins and others have contributed specimens collected by them in the Oriental region. South America is represented by planarians taken by Darwin, Fritz Müller, von Jhering and Plate. Nearly all the chief museums in Europe have contributed their specimens to von Graff, and in this manner he has been able, not only to more than double the number of species which were recognised when he began this work, but also to personally examine all but a very small percentage. To realise the rapidity of the increase in species of land-planarians during the last twenty years, it will be sufficient to state that Moseley's complete list, made in 1877, comprised only 63 forms, while 125 were known when von Graff began his monograph on the group, during the course of which he has added no less than 200 new species, and this, together with increments from other sources, makes a total of 348.

Of this unexpectedly large number (for it is about equal to all the other Turbellaria put together which have been really adequately described), less than a dozen occur (with the exception of the Manchurian sub-region) in both the Palæarctic and Nearctic regions. The majority come from South America, the Oriental and Australian regions. Even this statement, however, does not represent the richness of the tropics, for Australia is really the only country where land-planarians have been systematically collected and recorded. Our knowledge of the planarian fauna of Africa, India, China, Central and North America is almost a blank. And additions to it will no doubt be made, not only in these countries, but also in places in which naturalists have already sought planarians. The island of Celebes, for example, has been examined by several zoologists, who have searched for land-planarians, but without success. Hickson, and after him Max Weber, searched in vain. More recently, however, the Sarasins have thoroughly explored the island, and have brought to light a most interesting fauna. Von Graff shows that the land-planarians of North Celebes exhibit Oriental characters, those of South Celebes Austro-Malayan features. Altogether twenty-one Celebesian species are now known, and of these all but three are new. We refer to this point particularly as showing that we are only beginning to realise the variety of this element of the tropical fauna, and that years of work are necessary in any one country before the planarian fauna can be fairly estimated. In Ireland a new species has been found near Dublin, and two other additions to the land-planarians of Europe have been made quite recently.

The first part of von Graff's great work is devoted to a full statement of the anatomy and histology of land-planarians. This section must have involved a vast expenditure of labour. Direct observation of the anatomy of living or compressed specimens is impossible, owing to the amount of opaque pigment in the tissues. Even the external apertures are hard to discover. Dissection is precluded by the solidity and tenuity of the body. The only available means in the majority of cases is the laborious one of serial sections, and this method the author has applied to elucidate the structure of no less than eighty-two species.

The chief result obtained in this way is the uniformity of the general anatomical features. Land-planarians form a homogeneous group, and agree closely in structure with the marine Triclad Turbellaria so far as these are at present known. Their distinguishing features appear to be correlated with the terrestrial habit. Among these may be mentioned their greater size and more powerful musculature; the formation of a "keel" to the foot, and the abundance of glands both for lubricating the foot and for enveloping prey; their brilliant, often intensely brilliant, colouring; the presence of sensory thickenings and of sensory pits on the anterior part of the body; and, perhaps their most significant distinction, the presence of elaborate structures accessory to reproduction. The anatomy of some of the simpler land-planarians is, however, an almost exact repetition of an aquatic Triclad, and the retention of cilia in the epidermis points to the conclusion that in land-planarians we have the first stage in the evolution of a terrestrial group from an aquatic one.

The presence of three extreme forms of rod-like secretions and the absence of nematocysts are noteworthy features of the epidermal glands. "Flame-cells" and parts of the canalicular system of excretory vessels have been found. The nervous system exhibits an interesting series of modifications. In the most primitive members of the group—the broad, flattened neotropical Geoplanidæ—the central nervous system consists of a dense plexus forming a horizontal plate lying just above the ventral body-wall. From this plexus nerves are given off, which either at once enter some organ or join with their fellows to form a well-developed cutaneous nerve-plexus right round the body. There is no distinct "brain." In the narrower neotropical and Australian members of the same family, a concentration of this central plexus takes place along two admedian lines, and a marked anterior thickening indicates the "brain." In the other families, as the sense-organs, which are scattered in the Geoplanidæ, become massed in front, so does the individuality of the brain become more and more pronounced. These sense-organs are of four kinds. The tentacles with eyes at their bases, found only in two South American forms. A paired sensory ridge forming a margin to the anterior part of the ventral surface in Geoplanidæ, and to the dorsal and ventral edges of the "cephalic plate" of Bipaliidæ. These ridges are innervated by the cutaneous nerve-plexus. Then the sensory pits which accompany these ridges, but which are supplied direct from the central nervous system. Lastly, the eyes. Of these there are two kinds. One, with the usual Turbellarian type of structure, has the rods directed away from the light, and the nerve entering in front and not, as in most other Invertebrates, from behind. This kind of eye occurs not only down both sides of the whole length of the body in the Geoplanidæ, but also on the dorsal and even the ventral surface. In the Bipaliidæ such eyes are concentrated at the margin and angles of the "cephalic plate." The other type of eye is one common to most Invertebrates, but hitherto unknown in Turbellaria. It consists of a pigment cap with a nerve perforating it behind, and entering the rod-cells, which face outwards towards the light. Such are the large paired eyes of the Rhynchodemidæ, and they are often imbedded in the nervous matter of the "brain."

The most novel and richly illustrated section of the anatomical part of von Graff's volume is, however, that in which the unexpected complexity and variety of the reproductive organs is discussed. This chapter is a most important addition to Turbellarian anatomy, and the results well repay the labour which has been spent on its preparation and illustration.

The next section, a short one, is devoted to the habits of land-planarians. Here, as in the other sections, the author has collected and given *in extenso* all the essentially important information that has been previously obtained. In this section, however, he adds little to the observations of Darwin, Moseley, Dendy, von Kennel and others. Land-planarians, though capable of withstanding considerable variations of temperature, are almost instantly killed by contact with dry objects, and by immersion in water, whether fresh or salt. The majority flourish best in dark, moist places. They are nocturnal, living by day under stones and tree-trunks, under the sheaths of bananas, and on tree-ferns Some are actually subterranean, and live on earth-worms. These are blind. But most land-planarians are content with a diet of snails, woodlice and insects. *Rhynchodemus vejdowskyi* is one of the few diurnal forms. It not only crawls about by daylight, but moves with such grace and rapidity that when von Graff saw it at Buitenzorg he mistook it at first for a Myriapod. A species of *Geoplana* has been found in some numbers creeping on the pavement of Melbourne in broad daylight.

The coloured plates, which show the appearance and bizarre markings of land-planarians, form quite a feature of von Graff's work. The ground colour is usually diversified by mottling or by brilliant longitudinal stripes. Bold transverse bars of colour are comparatively rare, but they occur in a small group of each of the two families, Bipaliidæ and Geoplanidæ. It is an extremely curious fact that all the barred species of the former family are confined to the islands of the Malay Archipelago; all those of the latter to the Chilian sub-region, with a single exception found in Brazil.

With reference to any supposed significance of these colours, von Graff suspends his opinion. Dendy, it is true, has shown that *Geoplana* produces an unpleasant taste on the tongue, and that fowls readily pecked at this planarian, but would not swallow it. A casual experiment of this kind is, however, not sufficient to justify the assertion that the colours of the land-planarians are of the "warning" category. The great difficulty is how to explain the prevalence of such brilliant colours and definite patterns in a group which is almost exclusively nocturnal. Yellow is the commonest colour, then orange, red, green, blue and violet. In young specimens, the pattern is more sharply defined, and the pigment (which is present both in large, richly branched connective-tissue cells and in the parenchymatous matrix) relatively more abundant than in the adult. No experiments appear to have been made to test whether land-planarians possess the power of colour-change. As with many other groups of animals upon which elaborate anatomical monographs have been written, the physiology of land-planarians is practically unknown.

The distribution of this group is very interesting, and is clearly illustrated by von Graff both by tables of every species and by a coloured map. To one of the main facts, their rarity north of the Equator and their abundance in the tropics, I have already adverted. Another interesting and suggestive discovery is the large proportion which occur on islands. More than half of the known species (201 out of 348) are purely insular, and each of almost all these (186) is limited to one island. As showing that this is only one of several indications of the local distribution of many species, von Graff points out that only five land-planarians occur in two geographical regions, only twenty in two subdivisions of the six regions, and but eighteen in two parts of the same region separated by an arm of the sea. The land-planarians afford a striking proof of the value of the Sclater-Wallace regions, which accordingly are adopted by the author.

The Oriental region is, perhaps, the richest, certainly the best characterised. Five-sixths of the family Bipaliidæ are confined to this region, and the remainder occur in Madagascar (most of the species being peculiar to this island) and Japan. The land-planarians of the Australian and neotropical regions are alike in one striking feature. The family Geoplanidæ is practically divided between them. The neotropical members of the genus *Geoplana* include most of the flattened primitive ones, and also peculiar forms such as *Leimacopsis* and *Polycladus*. Von Graff goes so far as to share the opinion that this geoplanid fauna has arisen on a lost Antarctic continent, and has spread on the one hand to New Zealand and Australia, on the other to South America. The distribution of earthworms lends strong support to this view, as Mr. Beddard has shown.

The concluding section of the work is composed of full systematic descriptions of the families, genera and species. Von Graff makes five families: the Limacopsidæ, with two tentacles; the Cotyloplanidæ (an unnatural family), with suckers; the Geoplanidæ, with scattered eyes; the Bipaliidæ, with the eyes limited to the flattened "head"; and the Rhynchodemidæ, with a pair of large eyes. There are now nineteen genera, many of which are new.

This monograph will be of inestimable value to all naturalists interested in land-planarians, and the author is to be congratulated on having completed such a laborious task with unfailing accuracy. The lithographers and publishers deserve a special word of praise for the beautiful plates and printing which adorn this book.

F. W. GAMBLE.

## A SCIENTIFIC ENGINEER.

*Papers on Mechanical and Physical Subjects.* By Osborne Reynolds, F.R.S. Vol. i. Pp. xv + 416. (Cambridge: University Press, 1900.)

THE Cambridge University Press has during some years past contributed very largely to the progress of physical science by the issue of the collected works of great mathematicians and physicists. The volumes which contain the collected writings of Maxwell, Adams and Cayley form a rich storehouse of knowledge; and the efforts the Press has made to induce living writers, such as Kelvin, Stokes and Rayleigh, to edit their own papers for issue in a collected form deserve the gratitude of all students.

Among the latest of such reprints is the volume before us. Its author, Prof. Osborne Reynolds, has passed a busy life as a teacher in a great commercial and manufacturing city, and his collected papers testify to the breadth of his interests and the wide scope of his work.

The papers included in the present volume, some forty in number, were published between 1869 and 1882. They range over a great variety of subjects, from the tails of comets and the solar corona to problems connected with the steering of ships and the bursting of guns. In so varied a collection the relative importance of the different papers differs greatly, and yet all are interesting; and all have advanced the sum of human knowledge.

Indeed, on reading them, one cannot help regretting that the author's interests have been so widely diffused, and that he has not had the opportunity of concentrating himself on some one or other of the great engineering problems which await solution, applying to it his practical experience and insight and his mathematical skill.

An extract from the author's preface makes the cause of this clear. He writes:

> "As affording some explanation of the absence of any connection between many of the subjects in this collection of papers, it may be pointed out that these subjects have not been determined by arbitrary selection, neither have they been the result of following up one line of research. They have for the most part been suggested by the discrepancies between the results obtained in definite mechanical arrangements, such as occur in some parts of the large field of practical mechanics, and the conclusions arrived at as to what those results should be for the same circumstances, by means of geometrical and physical analysis, as far as this analysis was developed at the time."

But to turn to the matter of the papers; it would take too long to attempt to analyse them all; and, indeed, the results of the most important are now classic, *e.g.* those on the refraction of sound, the action of a screw propeller, the steering of screw steamers, and the explanation of the radiometer.

The two papers on the refraction of sound are numbered 16 and 22. Stokes had, seventeen years before the date of the first of these papers, suggested the reason why sounds are heard less distinctly against the wind than with it. It is due to the fact that the velocity of the wind rises as we ascend; hence when a sound-wave is travelling against the wind, the wave-velocity is less in the upper portion of the wave than in the lower; thus the wave-front is bent upwards, and the sound passes over the head of the observer. The same notion occurred to Reynolds; he verified it by direct experiment, and pointed out, moreover, that in ordinary conditions of the atmosphere the temperature falls as we ascend; hence from this cause also the wave-velocity is reduced, and the path of the sound is no longer straight, but curved, with the convexity of the curve turned downwards. If, however, it should happen that the air is warmer above than it is below, the reverse will be the case—the sound-waves will be bent downwards—the sound will thus be audible at a greater distance than previously.

The papers on the action of the screw propeller form an interesting series. The racing of a screw is proved to be due to the admission of air to the screw; this, it is shown, interferes with the power of the screw to obtain water, and also reduces the resistance which would otherwise be offered by the water the screw would get For consider a vertical plate, totally immersed in water, which is being pushed forward; its speed may be such that the water behind cannot remain continuously in contact with it. A vacuum will tend to form behind the plate; the limiting velocity at which this takes place will depend on the pressure in the water behind the plate; if no air can reach the plate, this pressure will be the atmospheric pressure, together with that due to the depth of water above the plate; if air can reach the space behind the plate, the limiting velocity will depend only on the pressure due to the water, and will be much less than in the first case. The blades of the propeller act like the plate; a stationary screw will be most effective in propelling water when it is turning so fast that a vacuum is just formed behind its floats, and the rate at which the water is driven past depends on the water pressure just close to the floats; if air can reach the floats, no vacuum can be formed; the pressure will depend only on the height of the column of water above the screw; the limiting velocity will be less than when the screw remained free from air.

The steering of screw steamers is dealt with in several papers laid before the British Association; three of these are reports of a committee appointed in 1875 to investigate the question. Of this committee Prof. Reynolds was secretary. Briefly, their researches confirm the theory he had advanced in a paper published in the *Engineer*, June 4, 1875, explaining the accident to the steamer *Bessemer*, which had failed to enter Calais Harbour on May 8 previously.

Prof. Reynolds pointed out

> "when a ship is stopping, the water will be following her stern relatively faster than when she is moving uniformly, and consequently that the effect on the rudder will be diminished; that the longer the ship the greater will be this difference; also that this effect is greatly increased when a ship is stopping herself with her propellers, as was the *Bessemer*, for since not only is the retardation of the vessel much more rapid, but the water has a forward motion imparted to it by the propellers, which motion, if the propellers are near the rudder, may be greater than that of the ship, in which circumstance the effect of her rudder's action will be reversed."

In the paper on the radiometer, "On the Forces caused by Evaporation from, and Condensation at, a Surface," the true explanation of its action is given in the concluding paragraphs. The paper deals in the main with the effects of evaporation and condensation in causing motion, but near the end the author writes:

> "Since writing the above paper, it has occurred to me that, according to the kinetic theory, a somewhat similar effect to that of evaporation must result whenever heat is communicated from a hot surface to a gas. The particles which impinge on the surface will rebound with a greater velocity than that with which they approached, and consequently the effect of the blow must be greater than it would have been had the surface been of the same temperature as the gas."

The longest paper in the collection is that on certain dimensional properties of matter in the gaseous state; it contains the results of a number of experiments on the thermal transpiration of gases through porous plates, and an extension of the dynamical theory to account for the phenomena.

Enough has been said, perhaps, to show the interest of the volume and the importance of the scientific results it contains. It is got up in the admirable manner which characterises the Pitt Press productions, and in form leaves nothing to be desired.

---

## COUNT SCHEIBLER'S SPORTING TOUR.

*Sette Anni di Caccia Grossa é Note di Viaggio in America, Asia, Africa, Europa.* By Count Felice Scheibler. Pp. xv + 525. Illustrated. (Milan: U. Hoepli, 1900.)

ENGLISHMEN are, perhaps, somewhat too inclined to believe that great game shooting is a special prerogative of the Anglo-Saxon; but the publication of the present work, together with the recently issued English translation of Count Potocki's "Sport in Somaliland," should do something to dissipate this mistaken notion. Count Felice Scheibler may, indeed, be said to be a "mighty hunter," and the frequent mention of his name in Mr. Rowland Ward's "Records of Big Game" will suffice to show that many of the animals that fell to his rifle have yielded trophies of more than usual size. As is indicated in the title of the volume before us, the author's seven years' hunting included experiences of the great game of all the four continents of the world although in Asia his travels were limited to India and Ceylon, and in America to the United States and the Dominion of Canada. A well written and well illustrated record of such extensive experiences could not fail to be of interest, not only to his brother sportsmen, but likewise to naturalists; and the present volume may be truthfully said to fulfil both these conditions. The 250 text-figures with which the work is embellished are for the most part reproductions from photographs taken respectively by the author, Prince di Teano, and Mr. Seton Karr, and are remarkable alike for the manner in which they have been executed and the care with which they have been printed. A large number of these illustrations deal with animals which were shot by the Count, and although most of these were taken after death, yet they frequently portray very clearly some of the more striking characteristics of the particular species. The views of scenery and hunting scenes are, moreover, specially good, and will give to stay-at-home readers an excellent idea of the nature of the districts in which sport was obtained, and of the mode in which various animals are hunted. Of especial interest is the photograph, on p. 176, of recently captured elephants crowded into a *kedda*, while those representing the elephant tamers at work are scarcely less attractive. Some of the titles to the illustrations, such as "Il bufalo record," are perhaps a little comic, but Italian, like French, has not yet evolved a sporting language of its own.

Although the author does not appear to have had the good fortune to discover any new species, his accounts of the habits of many of the less known forms will be found of considerable interest to the naturalist. And a gratifying feature is the attention paid to nomenclature, since this is a point in which sporting works are apt to be very deficient. In the employment of names like *Mazama columbiana* for the Columbian black-tailed deer, and *Taurotragus oryx* for the eland, the Count is, indeed, thoroughly up-to-date and ahead of most works on popular natural history.

Whether, however, the author confined his love for shooting within such limits as would meet with the approval of the recent congress on the preservation of great game is a question which may be left for others to answer. But the plate on p. 457, which represents three individuals of the common African rhinoceros, out of a herd of six, already fallen, while aim is being taken by the author at a fourth, is calculated to give rise to misgivings on this point.

Starting from Liverpool in 1889, Count Scheibler sailed for America, where he soon enjoyed excellent sport in the Rocky Mountains with "grizzly" and wapiti; afterwards proceeding to British Columbia, where he was successful in obtaining examples of the Rocky Mountain goat. At San Francisco he embarked for India, where his first experiences of sport were obtained in the fever-stricken Sandarbans of Lower Bengal. Proceeding northwards, he had the good fortune to be entertained by the Maharaja of Kuch-Behar, whose territories are now the finest sporting-grounds in India; and here he obtained, in addition to tiger, the large Indian rhinoceros, the gaur, and the wild buffalo. After a short sojourn in Gya and Ceylon, the party then crossed to Somaliland, which was at that time in its prime as a sporting country. From the Italian province of Erithræa the Count proceeded by sea to Zanzibar, whence he made a journey of considerable length into the interior of Equatorial Africa, obtaining specimens of Coke's hartebeest (*Bubalis cokei*), and the fringe-eared beisa (*Oryx callotis*). The final stage of the tour was Russia, where elk was added to the list of large game.

Although, as the author himself states, the work lays no claim to having advanced either zoological or geographical science, yet it may be commended as a very interesting account of types of animal life which are only too rapidly disappearing from the face of the earth. In fact, it is so interesting that there would seem a considerable probability that an English translation would be well received. R. L.

## OUR BOOK SHELF.

*Die Moderne Physiologische Psychologie in Deutschland.* By W. Heinrich. Pp. iv + 249. (Zürich: Speidel, 1899.)

*Zur Prinzipienfragen der Psychologie.* By W. Heinrich. Pp. iv + 74. (Zürich: Speidel, 1899.)

*An Outline Sketch, Psychology for Beginners.* By Hiram M. Stanley. Pp. 44. (Chicago: The Open Court Publishing Company, 1899. London: Kegan Paul and Co., Ltd., 1899.)

MR. HEINRICH'S two little works demand careful study as well thought-out and consistent expositions of a psychological attitude which is in many ways attractive. The author, who may be described as a disciple of Avenarius *minus* his master's metaphysics, holds strongly the necessity of making the principle of psychophysical parallelism, understood in the most rigid sense, the basis of all psychological inquiry, and would consequently recognise no causes or causal laws other than those of the physical and physiological series. He has little difficulty in showing that Wundt and other contemporary writers, who, while professing the doctrine of parallelism, believe in causal sequences between psychical states as such, are inconsistent with their own professions. That the inconsistency can be avoided, or that an intelligible account of human life can be given in terms of purely physiological sequences, is scarcely so clear. As the author himself admits, it is a necessary consequence of his theory that the only difference between rational and purely reflex reaction on stimulus is one of comparative complexity. Whether an account of human life which reduces all activity to the purely reflex type is not like the play of *Hamlet* with the part of Hamlet left out, he does not discuss. The question is, however, directly suggested by his contention that, in treating of the behaviour of our fellow-men, we have no right to introduce the notion of consciousness, but should confine ourselves to establishing physical relations between changes in their environment and their corresponding outward reactions. He seems to forget that language, for instance, loses half its significance if you neglect to observe that it not merely can be understood by a listener, but is meant by the speaker to be understood. And even if we could agree to take no notice of consciousness in our fellows, it still remains, as the author admits, to examine the relation between the environment, which on his theory all science describes, and ourselves the describers. Thus all the problems about the relation between consciousness and its objects which Mr. Heinrich banishes from our psychological study of our fellows return upon us as soon as we attempt to understand our own relation to our environment. Perhaps the chief value of the author's discussions is that by his insistence on the too often disregarded consequences of the doctrine of parallelism, he compels his readers to ask themselves whether the old belief in the interaction of mind and body is not, with all its difficulties, more satisfactory than the fashionable substitute for it.

It is painful to turn from Mr. Heinrich's able and thoughtful work to such a piece of loose and unsatisfactory popular psychology as Mr. Stanley's essay. If psychology is to be taught in schools at all—in itself a debatable question—it ought, at least, to be taught in a precise and definite form. These scraps of inaccurate chatter are of no more value in psychology than they would be in elementary physics or in any other science. Read, for instance, the light and airy sentences (pp. 8–9) in which Mr. Stanley disposes of the difficult problem of space-perception. What would be thought of a writer on heat or chemistry who should evade all the puzzles of his subject by such loose and flimsy generalisation? In truth, the only way to treat work of this kind with kindness is to say nothing at all about it. The only words one can find in which to characterise it are that, like a good deal of popular writing on psychological topics, it is quite worthless, because the writer has set no serious standard of scientific accuracy before him.

*Rural Wealth and Welfare: Economic Principles illustrated and applied in Farm Life.* By Geo. T. Fairchild, LL.D. (New York: The Macmillan Company, 1900; London: Macmillan and Co., Ltd.)

THE scope of this treatise is perhaps more accurately indicated by its alternative title: it is primarily a textbook of economics, the concrete illustrations being taken preferably from objects and practices familiar to agriculturists. The book is accordingly addressed to this class of the community, though it may be doubted whether the ordinary farmer, at all events in this country, will be competent to make much practical use of the principles expounded. The position of farming, especially in the older civilised States, has perhaps undergone more change during the last thirty years than that of any other great industry, since it is practically within this period that the cultivator has had to learn to face the competition, not merely of his own countrymen, but of the whole world. It is therefore all the more necessary that he should be thoroughly acquainted with the modern conditions under which he has to work; in this respect, the remarks on the importance, as a factor in prices, of the increased facilities for marketing the enormous quantities of grain and other farm products raised in the United States, are very much to the point.

*Lectures on Theoretical and Physical Chemistry.* By J. H. van 't Hoff. Translated by R. A. Lehfeldt. Part ii. Chemical Statics. Pp. 156. (London: E. Arnold.)

WE welcome the appearance of the English translation of the second part of van 't Hoff's lectures. Dr. Lehfeldt has, as before, done his work admirably. It may be regretted, however, that he has adhered so closely to the somewhat uncouth structural formulæ used by the author. We venture to hope that in a future edition a freer use of brackets and points may be made, as the student might have some difficulty in recognising aceto-acetic ether in the formula $H_3CCOCH_2CO_2C_2H_5$.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Eclipse Photography.

THE writer has obtained results in photography which seem to have an important bearing on the work which should be undertaken in future eclipses.

It is well known that photographic plates exposed in some eclipses have developed no trace of an image of the sun. The astronomer has even been subjected to the mortifying suggestion that he had forgotten to uncap his camera. It is not difficult to reproduce such results at any time by simple over-exposure. In eclipse photography, where it is sought to get the most delicate of details in an object of the most delicate character, the methods now used are hedged in by very peculiar limitations. It requires a very appreciable time to secure delicate details, and, nevertheless, if this time is made too great the plate will fog. The developer must then be given restraining properties, which cause a loss of the very details we are seeking to secure.

In a paper recently published by the Academy of Science of St. Louis, the writer has shown that a plate which, on account of over-exposure will develop as a zero plate in a dark room, will develop as a positive in a light room. The paper contains a half-tone reproduction of a positive obtained by a camera exposure of one minute, and developed within a few inches of a 16-candle incandescent lamp. The plate was an "instantaneous" Cramer plate. Since that time the same results have been reached by first opening up the plate holder and exposing the film to the lamp light until it is all converted into the zero condition. If covered with an opaque punched stencil, no trace of the design will appear on the film when developed in the illuminated bath. The slide is then closed and the plate afterwards exposed in the camera in the usual way. Such a plate cannot be over-exposed in any reasonable time. It may be exposed for a minute or for four hours to a brilliantly-lighted landscape, and the most superb results can be obtained. There is no restraining developer needed. The tendency to fog when the exposure is too short is corrected by taking the developing bath nearer to the light. It seems probable that on very short exposures it might sometimes be advantageous to use a developer which will yield a positive with an under-exposed plate. In the two eclipses of long totality which are now approaching, this method seems to promise very valuable results, and the attention of those who will have the work in charge is earnestly directed to this matter. The results described have been reached but recently, and there is need of preliminary experimenting by any one who wishes to avail himself of these methods.

St. Louis, Missouri, U.S.A. FRANCIS E. NIPHER.

### The Action of Water Upon Glass.

IT is a matter of too frequent observation in India that lenses of optical instruments are liable to serious injury from atmospheric influences. This very often takes the form of injury to the Canada balsam cementing the two lenses of achromatic combinations together; but in other cases, it is due to the solvent action of water on the surface of the glass. As this is a matter of importance necessitating the re-grinding of the lens for its correction, I have thought that the following observations may be of interest and of value to optical instrument-makers, especially as it appears that only particular kinds of glass are attacked in this way. If that is so, it should be possible to avoid using glass of that particular composition; or the edges of the combined lenses may be covered with a coating of cement or varnish so as to prevent moisture getting in between them, and in such a way that it could easily be removed when desired.

My attention was first drawn to some cases of articles of domestic glassware being attacked by water standing in them for some time, and these are recorded to show that a solvent action does take place. The first case that I noticed was that of a cut wine glass which was used—or misused—to hold a few cut flowers. On seeing it dry on one occasion, I noticed it had a dull matt appearance, which I thought was simply a deposit. On examination, however, I found that the surface of the glass had been eaten into up to the level of the water usually put into it.

The next case was that of glass finger-bowls, in which the servants kept water ready for use. These were similarly attacked up to the level of the water. The next was a more remarkable case. A couple of decanters, not required for use, had evidently been washed and drained, more or less, but not dried; possibly during the hot season. The moisture remaining inside had become deposited on the inner surface in droplets, as, indeed, may frequently be seen, and had been standing so for some time. When dried for use the surface was found to be eroded, giving a pattern precisely similar to that formed by condensed moisture: leaving no doubt as to its cause.

Here we have, then, a case of pure water attacking the surface of glass when allowed to stand for some time. Since then, being on the alert, I have met other cases, including some of perfectly new glass articles eroded in like manner, which, without their history, it is impossible to account for.

Now for two instances of physical apparatus being attacked and spoiled by this action. The first noticed was a Newton's Rings apparatus. In this case the two discs of glass were equally attacked, and so much so that the combination was of a dense matt appearance. On opening it out, the discs were found to be firmly adhered, and on inserting a knife edge between the discs and giving a sharp tap on the back to separate them, an irregular piece about 1¼ inch long came from one adhering to the other. The two had thus grown together, and at the junction was actually stronger than in the mass of the glass.

The next was a more serious case, being the object lens of a 3½ inch telescope from a well-known London firm of optical instrument-makers. In this case, the convex lens was badly corroded on its inner surface, though the adjacent face of the concave lens was quite clear. Here we see the difference in action in the case of two different kinds of glass. This, however, would help us little if all kinds of crown glass (of which the convex lens is made) were similarly attacked. But this is not the case, and it is a point of importance to opticians to ascertain what particular kinds of crown glass used in achromatic combinations are liable to this action, and to avoid using them. Of a fairly large number of achromatic combinations I have in the College Laboratory, this is the only one that has been affected, though all are exposed to the same influences, while some belong to old pieces of apparatus. The particular telescope was purchased about six years ago, and the damage took place in one season when it was not much used. Since then I have from time to time opened out the lenses and have frequently found a layer of moisture between them; in one case, of a commoner piece of apparatus in which the lenses did not fit closely, a complete drop of water was collected, the diameter of the lens being only 1½ inch; and in a Soleil's saccharimeter, clear through vision is obscured by moisture collected and condensed on the surfaces of the lenses in one of the adjusting pieces, which it is very difficult to open out to clean.

All this shows that moisture does collect in the form of water between such layers of glass, and the pattern of the eroded portion of the telescope lens, together with the instances of the action of water on the domestic glass goods mentioned above, leave no doubt that it was moisture alone that caused the damage in this case, although it was not actually seen. I need hardly say that, in both the Newton's Rings apparatus and the telescope lens, the exposed surfaces were perfectly clear and unacted upon.

The causes of moisture collecting in this way would appear to be the excessive moisture in the air for many months in the year, the hygroscopic nature of the glass, and capillary action between the surfaces; while the apparently marked action of water on glass here noticed is probably due to the long-continued higher temperature. It is possible, however, that the above phenomena may not be as new or unusual as they appear to be to me, and that many others could give like experiences.

EDMUND F. MONDY.

Dacca College, Dacca, East Bengal, June 16.

## *THE TOTAL SOLAR ECLIPSE AS OBSERVED BY THE SMITHSONIAN EXPEDITION.*

WADESBORO, in Northern Carolina, was the station selected by the Smithsonian Institution for observing the total solar eclipse of May 28 last. The chances of fine weather at eclipse time were about eight to one, and it is satisfactory that on eclipse day the sky was cloudless and the air clearer than on the average.

The main objects of the investigations undertaken were a photographic and visual study of the structure of the lower corona, and a determination by the bolometer of the heat radiated from it, and lastly an examination of the form of its spectrum energy curve.

Prof. Langley, who was in charge of this expedition, observed the eclipse of 1878 from Pike's Peak (14,000 feet), and he was then particularly struck by the remarkable definiteness of filamentary structure close to the sun's limb, a structure which, he remarks, has never been found in any photographs, not even in those beautiful pictures taken by Prof. Campbell at the Indian eclipse of 1898. The eclipse this year afforded him an opportunity of examining this inner corona region with a much more powerful instrument. This instrument was a 12-inch achromatic lens of 135 feet focal length, obtained for the Harvard College Observatory, and lent by Prof. E. C. Pickering. The tube was mounted horizontally in conjunction with a cœlostat of 18-inch aperture, and 30-inch square plates were used, the diameter of the solar image being 15 inches. To supplement this instrument, a 5-inch lens of 38 feet focal length, loaned by Prof. Young, was pointed directly at the sun, and photographs were secured on plates 11 by 14 inches, moved in the focus of the lens by a water clock. For the study of the outer corona and possible intramercurial planets, specially equatorially mounted lenses of 6-, 4- and 3-inch apertures, driven by clock-work, were used.

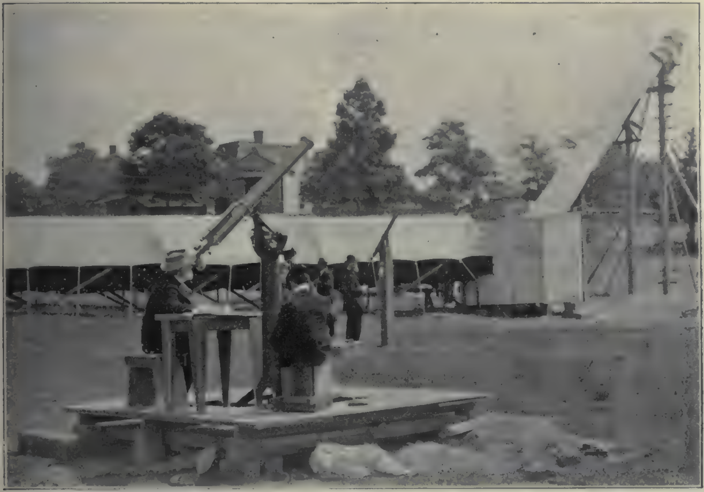

FIG. 1.—Portion of Smithsonian Astrophysical Observatory Eclipse Camp, showing a part of the large 135-foot telescope (under canvas), the 38-foot coronagraph, and the 5-inch equatorial.

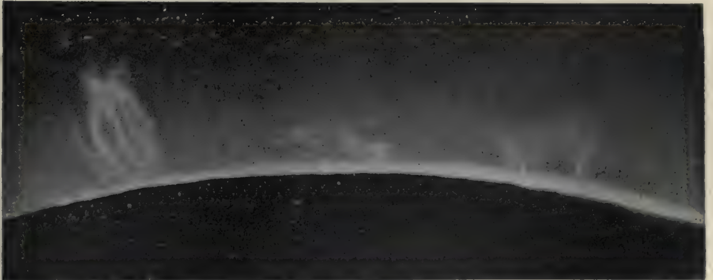

FIG. 2.—Showing prominences at the south-west limb. Taken with a 12-inch lens of 135 feet focal length. Exposure eight seconds. At end of totality. (Natural size of original photograph. Moon, 15 inches diam.).

The accompanying illustration (Fig. 1) shows a small part of the 135-foot telescope. The photographic hut is seen at the end of it, and beyond that the tube containing the lens of 38 feet focal length pointed at the sun. Prof. Langley is seen observing at the 5-inch equatorial.

For the bolometric work a massive siderostat with a mirror of 7 inches was used in conjunction with a large part of the delicate adjuncts employed at the Smithsonian Institution in recent years.

Further work that was attempted, and for which other apparatus had been taken out, was an automatic method of obtaining photographs of the lower chromosphere at about second contact by means of an objective prism working in connection with the 135-foot lens; visual and photographic observations of times of contact; and sketches of the corona, both from telescopic and naked eye observations.

The observers, under the general charge of Prof. Langley, were distributed as follows:—Prof. Langley used the same 5-inch as he observed with in 1878; Messrs. Abbot and Mendenhall were in charge of the bolometer; Mr. T. W. Smillie made exposures at the 135-foot telescope, and Mr. F. E. Fowle, jun., at the 38-foot telescope. Father Searle, assisted by Mr. P. A. Draper and Mr. C. W. B. Smith, employed four telescopes, mounted on a single polar axis and driven by clock-work, for obtaining photographs of the outer corona and the intramercurial planets. Latitude, longitude, time and contact observations were made by Mr. G. R. Putnam, assisted by Mr. Hoxie. Sketches of the inner corona and contacts were made by Mr. R. C. Child with a 6-inch, and by Father Woodman with a 3½-inch.

Among the more general observations made at the time of the eclipse may be mentioned the following:—

Before totality a fall of temperature and a rising breeze were distinctly noticeable. Shadow bands were seen, but their velocity was too rapid and flickering for accurate determination; their size and distance apart (about 5 inches) were also estimated.

During totality the sky to visual observers was notably not dark, and no second magnitude star was seen with the naked eye. Mercury was a conspicuous object

The equatorial streamers were closely observed, and could be followed by the naked eye to 3 or 3½ solar diameters; their structure was likened by Father Woodman to a structure of mother-o'-pearl, and this was generally conceded. Colour estimates, however, varied, and were given as "yellowish green tinge," "straw-coloured" or "golden." (It may be remarked here that the general description of the colour was given by the British observers in Spain and Portugal as "silvery-white.") Prof. Langley's visual telescopic observations gave, as he remarks, "little indication of the finely-divided structure of the inner corona which he had noticed at Pike's Peak. Structure, to be sure, was evident, but not in such minute subdivision as had then been seen; and though one remarkable prominence, as well as several smaller ones, was visible, the coronal streamers did not give to the writer the impression of being connected with these prominences, though the relationship of some of them to the solar poles was abundantly manifest."

The approximate length of totality as observed was 88 seconds, or 4 seconds shorter than the duration as given by the *Nautical Almanac*.

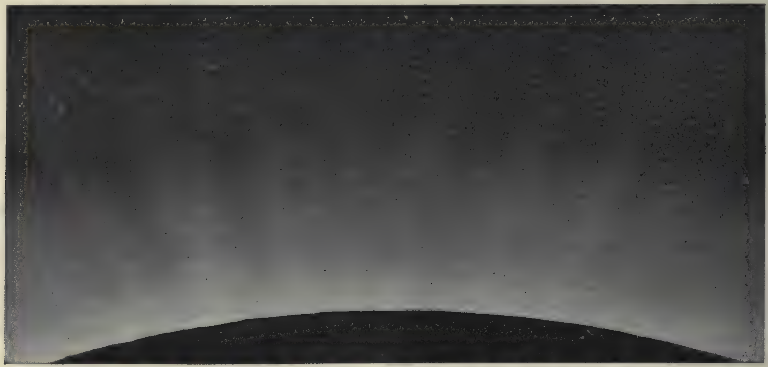

Fig. 3.—North polar coronal region. Taken with a 12-inch lens of 135 feet focal length. Exposure 16 seconds. (Natural size of original photograph. Moon 15 inches diam.)

With regard to the photographs which were found to have been successfully exposed, but of which only a few have as yet been developed, most interesting results will be obtained. During totality six plates were exposed for periods ranging from ½ to 16 seconds, and three others immediately after third contact; these were all secured by the large 135-foot telescope. We are fortunately able to illustrate two portions (natural size) of the large 15-inch disc. Fig. 2 shows one of the principal prominences with the lower filaments near it (exposure 8 seconds), while Fig. 3 is another portion of the north polar region, with a 16 seconds' exposure. The part near the sun has been intentionally over-exposed, to show more clearly the outer portions of the polar structure, which extended to 6 minutes from the sun. The wealth of detail and imposing magnitude of the scale on which these pictures are taken will no doubt give us much needed information about the structure of the corona just above the chromosphere.

The measurement of the heat of the corona appears to have been successfully performed by Mr. Abbot, with the aid of Mr. Mendenhall, and this is probably the first time that it has really been shown to exist. The important result was that the corona gave a positive indication of heat as compared with the moon; this heat though certain, was, we are told, too slight to be subdivided by the dispersion of the prism with the means at hand.

With regard to the negatives depicting the outer corona, these show the extensions reaching to from 3 to 4 solar diameters for the longest streamers.

The plates taken for a search for intramercurial planets have not been carefully examined, but the considerable sky illumination during totality leads Prof. Langley to doubt the possibility of having recorded the images of such faint objects on the plates. Pleione (6·3 magnitude) in the Pleiades, and some fainter stars are, however, recorded on one of the plates.

The expedition seems to have gathered some most valuable data, and to have scored a decided success in every respect; the observations made and the photographs secured promise to be very satisfactory, especially with regard to the primary objects of the expedition.

## *THE BOARD OF EDUCATION AND ITS CONSULTATIVE COMMITTEE.*

It will be remembered that the Board of Education Act, which received the Royal Assent last year, contained in Section 4 the following provision:

"It shall be lawful for Her Majesty in Council by Order to establish a Consultative Committee, consisting, as to not less than two-thirds, of persons qualified to represent the views of universities and other bodies interested in education, for the purpose of:—

(*a*) framing, with the approval of the Board of Education, regulations for a register of teachers which shall be formed and kept in manner to be provided by the Order in Council; provided that the register so formed shall contain the names of the registered teachers arranged in alphabetical order, with an entry in respect of each teacher showing the date of his registration, and giving a brief record of his qualifications and experience; and

(*b*) advising the Board of Education on any matter referred to the committee by the Board."

The Order in Council nominating the members of the proposed committee and defining its course of procedure, has just been issued, and is a document of considerable public interest and importance. Advisory Boards are not unknown in other departments of the public service, *e.g.* in the India Board and at the Admiralty; but a permanent Consultative Committee of unofficial experts, on the scale and with the powers contemplated in the present Order in Council, is a novelty in administration; and the working of the new experiment will necessarily be watched with much solicitude by all persons who have at heart the improvement and development of our system of public education.

The following are the names of the eighteen persons who are nominated as the first members of the Consultative Committee:—

Right Hon. Arthur Herbert Dyke Acland.
Sir William Reynell Anson, Bart., M.P.
Professor Henry Armstrong.
Mrs. Sophie Bryant.
Right Hon. Sir William Hart-Dyke, Bart., M.P.
Sir Michael Foster, K.C.B., M.P.
Mr. James Gow, Litt.D.
Mr. Ernest Gray, M.P.
Mr. Henry Hobhouse, M.P.
Mr. Arthur Charles Humphreys-Owen, M.P.
Sir Richard Claverhouse Jebb, M.P.
Hon. and Rev. Edward Lyttelton.
Very Rev. Edward Craig Maclure, D.D., Dean of Manchester.
Miss Lydia Manley.
The Ven Ernest Grey Sandford, Archdeacon of Exeter.
Mrs. Eleanor Mildred Sidgwick.
Professor Bertram Coghill Alan Windle, M.D.
Rev. David James Waller, D.D.

It will be noticed that with the exception of the two former Vice-presidents of the Council, and of Mr. Hobhouse, all the persons named in this list may be regarded as representatives of "bodies interested in education." Oxford, Cambridge and London are most appropriately represented by their respective Members of Parliament; two of the proposed members are head-masters of public schools, one has been a teacher in a public elementary school, one is a High School mistress, another lady is the head of Newnham College, a third is the mistress of a training college for schoolmistresses, and may also be reckoned as a representative of the British and Foreign School Society. Science and technology have their advocates in Prof. Armstrong and Sir Michael Foster; the Established Church and the National Schools are represented by Archdeacon Sandford the Roman Catholics by Prof. Windle, and the Nonconformists by Dr. Waller, Wales and the Welsh Intermediate Schools by Mr. Humphreys-Owen, and the School Boards of England by Dean Maclure, the chairman of the Manchester School Board. There can be no doubt that an excellent selection of names, typical of various classes, and likely to command the public confidence, has been made by the Lord President and his advisers.

Nevertheless, it was generally hoped and expected that, while two-thirds of the number were very rightly and in fulfilment of the express intentions of the Act to be composed of persons able to express the views of different academic and professional bodies, the remaining third would consist of persons detached from sectional interests, and specially qualified by breadth of view, by large acquaintance with schools and institutions of various classes, both here and in foreign countries, and by a disinterested concern for the interests of national education as a whole, to render service in consultation with the Board of Education. No such proportion has, however, been observed in the composition of this committee. Like some recent Royal Commissions, to which have been entrusted duties especially demanding wide knowledge and judicial impartiality, the chief ingredients in the committee are advocates and partisans specially charged to look after the interests of particular institutions, creeds, or professional bodies. It appears to be assumed that the resultant of all these opposing forces will be a satisfactory conclusion. But when it is considered that one of the first duties of the committee will be to determine the conditions on which teachers shall be admitted to the official register, and that it will be the task of that committee to determine the kind of qualification which should be recognised, and the relative claims of a great number of different institutions, both public and private, it becomes evident that the list of the proposed committee is seriously incomplete. One of the most important questions which will in due course inevitably demand its attention is the examination and inspection of secondary schools, and it is quite conceivable that on this point professional interests may not prove to be precisely identical with the public interests. It may be hoped that attention will be given to these considerations before October, when the committee is for the first time to be summoned. It is indispensable that a body charged with such novel and weighty responsibilities should from the first command the full confidence of all those who are conscious of the defects in our present system, and who are concerned more with its due expansion and its fulfilment of high national ideals than with the conservation of any traditions and interests, however important and deserving of respect, which belong to particular classes or institutions.

---

## *THE INTERNATIONAL ASSOCIATION OF ACADEMIES.*[1]

THE Academy will recall the fact that at the conclusion of the mission entrusted to M. Moissan and myself, consent was given to the "Projet de Statuts pour l'Association internationale des Académies," drawn up by the delegates of the nine Academies represented at the Conference held at Wiesbaden early in October last, at the invitation of the Academy of Berlin.

The International Association is now constituted; and it includes the eighteen following Academies:

| | | |
|---|---|---|
| 1. | Academy of Sciences ... ... ... | *Amsterdam.* |
| 2. | Prussian Academy of Sciences ... ... | *Berlin.* |
| 3. | Academy of Sciences, Literature and the Fine Arts ... ... ... ... | *Brussels.* |
| 4. | Hungarian Academy of Science ... | *Budapest.* |
| 5. | Academy of Sciences ... ... ... | *Christiania.* |
| 6. | Society of Sciences ... ... ... | *Göttingen.* |
| 7. | Academy of Sciences of Denmark ... | *Copenhagen.* |
| 8. | Academy of Sciences of Saxony ... | *Leipzig.* |
| 9. | Royal Society ... ... ... ... | *London.* |
| 10. | Academy of Sciences of Bavaria ... | *Munich.* |
| 11. | Academy of Inscriptions and Literature | *Paris.* |
| 12. | Academy of Sciences ... ... ... | *Paris.* |
| 13. | Academy of Moral and Political Sciences | *Paris.* |
| 14. | Academy of Sciences ... ... ... | *St. Petersburg.* |
| 15. | Academy dei Lincei ... ... ... | *Rome.* |
| 16. | Swedish Academy of Sciences ... ... | *Stockholm.* |
| 17. | Academy of Sciences ... ... ... | *Washington.* |
| 18. | Academy of Sciences ... ... ... | *Vienna.* |

Amongst the Academies invited to join, one only, the Royal Academy of History of Madrid, has as yet not replied to the request of the Wiesbaden Conference.

The provisional rules take into consideration the possibility of the addition of other learned societies, and in § 2 the conditions and formalities are indicated which will be necessary for the admission of a new Academy.

The Association comprises two Sections, the Section of Literature and the Section of Science. The work will be carried out by general meeting and committee. In principle, the general meeting will be held every three years, and each Academy will send as many delegates as it may deem necessary, but each Academy will have only one vote, which should be given by one of the members of the delegation.

In the interval between two general meetings, the Association is represented by the committee, each

---

[1] Translation of a report made to the Paris Academy of Sciences on July 2, by M. Darboun, permanent secretary of the Academy.

Academy being represented on this by one member only, if it concerns itself with only one of the Sections of Literature or Science; it will send two delegates when it is concerned with both Sections. Amongst the eighteen Academies, twelve belong to both Sections and consequently will send two delegates to the committee. Of the other six, four, namely the Royal Society of London, the Academy of Sciences of Paris, the Academy of Stockholm, and the National Academy of Washington, belong to the Section of Science alone, and two, the Academy of Inscriptions and Literature, and the Academy of Moral and Political Sciences, belong to the Section of Literature. Hence the committee will consist of thirty delegates, of which sixteen will belong to the Section of Science, and fourteen to that of Literature. In full committee the two delegates of one Academy will have only a single vote. After delay, inevitable in such cases, all the Academies, with the exception of two or three, have sent in the names of their delegates. The delegate of the principal Academy will take the chair at the committee of the Association, the principal Academy being that of the place in which it is proposed to hold the next general meeting.

The Conference of Wiesbaden having decided on a resolution to which we can here only draw attention, that the first general meeting of the International Association should be held in Paris this year, a difficulty has arisen not foreseen when the provisional rules were drawn up. Three Parisian Academies having joined the Association, it is necessary to decide to which shall be assigned the Presidency on this occasion. The delegates of the three Academies of the Institute of France have met, and have unanimously decided to confer for this year the presidency of the Association upon the Academy of Sciences, which was the first to join the Association, and, moreover, has taken an active part in the discussions, at the conclusion of which the Association was constituted.

It has been further decided that the first Session of the committee shall be held in Paris towards the end of July, the first meeting being fixed for Tuesday, July 31, at 9.30 a.m., at the Palais de l'Institut.

The agenda for the first meeting will include the preparation of a scheme of government for the committee, the settlement of the exact date and the order of the day for the next general meeting. The Royal Society of London, which has taken so active a part in the formation of the Association, has already announced a scheme which it proposes to submit for approval to this next general meeting; it concerns the measurement of an extended arc of a meridian in the interior of Africa.

The Academy, by the act of joining, has subscribed to the rules of the new Association. There is no occasion to recall here with what prudence and moderation they have been drawn up. The object of the Association is to prepare and promote scientific work of general interest which may be proposed by one of the constituent Academies, and generally to facilitate scientific relations between different countries. In any particular case, each Academy reserves to itself the right to give or refuse its support, or decide the choice of methods and the means to be employed.

If these principles are followed, the Association will become a powerful instrument of study, of concord and of scientific progress; it will rapidly take its place in the front rank of those international scientific associations, the *rôle* of which must necessarily be satisfactory.

Faithful to the principles which they have always followed, the three Academies of the Institute of France, called by the nature of their studies into the Association, will strive to assure it the success and influence which have been desired for it by its promoters.

Finally, attention may be directed to a particular clause in the rules which will interest some of our colleagues. For taking into consideration the study or preparation of scientific enterprises or researches of international interest, upon the proposition of one or more of the associated Academies, special international commissions may be instituted either by the general meeting or one of its two Sections, or, in the interval between two general meetings, by the committee or one of its two Sections.

## *THE NEW PHYSICAL LABORATORY AT OWENS COLLEGE.*

OWENS COLLEGE recently held high festival on the occasion of the opening, by Lord Rayleigh, of the new physics laboratories. Of these, a preliminary account was given in NATURE of October 27, 1898, on the occasion of the laying of the foundation-stone. As the size of the new building surpasses that of any other physical laboratory in this country, it was fitting that the occasion should be marked by a ceremony of some importance, and dignified by the presence of a number of leading physicists from all parts of the country.

The main features of the new laboratories, as planned by Prof. Schuster, were described in our former article; but it remains to state how they have been carried out. The new building is separated by Coupland Street from the main quadrangle of buildings of which Owens College consists, though it is joined to the older buildings by an underground passage. It is a commodious structure, having three complete storeys above the basement, with simple but effective decorative features both internal and external. The frontage is about 110 feet wide, and the main building extends about 90 feet back. The ground floor is devoted to rooms for electrical measurement, the magnetic testing of iron, electrochemistry, a workshop and a private laboratory. The first floor contains a large laboratory for elementary teaching (36 feet by 44 feet in dimensions), a balance room, a room for chemical physics, two laboratories for electricity and one for optics. On the second floor is a fine lecture theatre with raised auditorium, preparation room, museum and apparatus room, a class-room and two smaller laboratories, and a special room fitted up for physical optics; its special feature being the equipment, designed by Sir Howard Grubb, necessary for working with a 6-inch Rowland grating. From this floor an upper staircase leads to a small astronomical observatory containing an excellent 10-inch equatorial by Cooke, the gift of Sir Thomas Bazley. In the basement are rooms for spectroscopic and photographic work, a cryogenic laboratory and a room for researches at constant temperature. The arrangements for heating, ventilating, and for the supply of gas, electricity, water, steam and compressed air are exceedingly complete. In the ventilation system, the air supplied through a fan and warmed by passage through a flue heated by the gases of the boiler-furnaces, is passed over a surface of oil to deprive it of its dust and prevent blackening effects.

A very important adjunct to this fine building is the John Hopkinson memorial wing for electrotechnics. This consists of two large rooms on the ground floor: one (27 feet by 50 feet) to serve as a dynamo room, the other an electrochemical laboratory (36 feet by 37 feet), together with basement rooms for gas engine, countershaft for dynamo-driving, photometers, and heating apparatus. In the dynamo room, where already are placed several of Wilde's dynamos and some more recent types, there is a fine bronze portrait tablet of the late Dr. Hopkinson. The cost of this wing has been defrayed by the parents and relations of the lamented Dr. Hopkinson, who was himself an alumnus of Owens College.

The opening ceremony on the 29th ultimo began with an academic procession from the Christie library to the lecture theatre of the new laboratories, where the chair was taken by the Treasurer of Owens College, Mr. Alderman Thompson. Amongst those present were Lord Rayleigh, Prof. Schuster, Sir Henry Roscoe, Principal Hopkinson, Prof. Oliver J. Lodge, Prof. Bodington (Vice-Chancellor of Victoria University), Prof. Rücker, Prof. Pickering of Harvard College, Prof. Osborne Reynolds, Prof. Stroud, Prof. J. J. Thomson, Prof. Poynting, Prof. Ramsay, Prof. Core, Archdeacon Wilson, Mr. Wimshurst, Prof. Perry, Mr. W. Mather, M.P., and many others. Lord Rayleigh delivered a short address upon physical laboratory work and research, and formally pronounced the building open. Prof. Schuster gave an account of the aims of the building, and of the various stages in their realisation. Prof. Pickering likened a physical laboratory to a battleship, and enlarged upon the uses of its equipment. The company then adjourned, some to visit the various rooms, others to attend the opening ceremony in the John Hopkinson memorial wing, which was presented in a touching speech by Mr. Alderman Hopkinson on behalf of the family.

A garden-party held in the afternoon in the house of Prof. Schuster was followed in the evening by a reception and conversazione in the new building. In one of the rooms was a very interesting exhibit of some of the apparatus used by Joule, including two "current weighers," a tangent galvanometer, and a mercury pump. These have been presented to the Owens College by Mr. B. A. Joule. In another room Mr. T. Thorp showed his celluloid gratings and celluloid reproductions of Rowland's grating and of his own echelon grating. Mr. Wilde exhibited his magnetarium and a number of lunar photographs. The large electro-magnet presented by him was also shown in operation.

On the morning of the 30th was the annual ceremony of conferring of degrees of the Victoria University. This took place in the Manchester Free Trade Hall, which was crowded with undergraduates and visitors. The Chancellor, Earl Spencer, presided with great dignity. Honorary degrees were conferred on Lord Rayleigh, Sir William Huggins, Sir William Abney, Sir William Roberts-Austen, Dr. T. E. Thorpe, Prof. Dewar, Prof. Forsyth, Mr. R. T. Glazebrook, Mr. Sidney Lee, Prof. E. Pickering, Prof. J. J. Thomson, and last on the father of the profession of electrical engineering, Mr. Henry Wilde. The ordinary degrees were then conferred upon the successful candidates of the year from the three constituent colleges—Owens College, Liverpool University College, and the Yorkshire College. A luncheon in the Town Hall, given by the Lord Mayor, was subsequently partaken of by the Chancellor, the new Honorary Doctors, the University Professors, and a large number of distinguished visitors.

It has been mentioned that the new physics laboratory exceeds in size any other similar building in England. It is, however, smaller than the physics laboratories of Baltimore, Darmstadt and Strassburg. Its cost has been defrayed by the generosity of private individuals.

---

## *NOTES.*

Two deputations have recently waited upon Mr. Hanbury to put before him the two sides of the question referring to the proposed establishment of the National Physical Laboratory in the Old Deer Park at Richmond. On one side are some naturalists and inhabitants of the neighbourhood, who protest against the proposed buildings as an interference with the amenities of the neighbourhood of Kew Gardens; on the other are the physicists and the members of the Committee, which, after giving great attention to the question of site, decided that Kew was most suitable. It is a little unfortunate that this difficulty should have arisen, and it could probably have been avoided by the exercise of a little tact and consideration when selecting the site for the laboratory. Much of the misapprehension which at present exists as to the character of a physical laboratory might thus have been removed. Some people seem to think that the fifteen acres required will be covered with buildings in which noisy operations comparable with those of large engineering workshops will be carried on. This, of course, is entirely incorrect. In the first place, the actual area to be covered by buildings is only a quarter of an acre, or the sixtieth part of the whole area proposed to be taken, and secondly, quiet and freedom from all the perturbing characteristics of towns and manufactories are essential for the investigations to be carried on in the laboratories. When this is kept in mind, the alarm of a certain portion of the public, especially those who appreciate the beauties of Kew Gardens, that the buildings would break the present charm, seems a trifle unnecessary. The Observatory being already in the Old Deer Park, it is natural and proper that the laboratory, which is under the same administration, should be there too. As, however, the Park is over 350 acres in extent, it ought not to be difficult to find another suitable site if there is a persistent opposition to the one already selected. In any case, we are convinced that a *modus vivendi* could be arrived at if the representatives of the opposing interests were to meet one another in a conciliatory spirit.

M. ZAMBACO has been elected a correspondant of the Paris Academy of Sciences, in the section of medicine and surgery.

DR. CORFIELD, professor of hygiene and public health at University College, has been elected a Foreign Corresponding Member of the Royal Academy of Medicine of Belgium.

MR. J. H. MAIDEN, director of the Botanic Gardens, Sydney, is expected to arrive in London at the end of the present month, and will be in the United Kingdom and on the Continent for about three months, engaged in special investigations in botany and agriculture.

THE Duke of Northumberland has been elected a trustee of the British Museum.

THE annual meeting of the Victoria Institute will be held on Monday next, July 16, when an address will be delivered by Prof. Hull, F.R.S.

IT is announced in the *Athenaeum* that Baron von Richthofen has been nominated Director of the newly founded Museum für Meereskunde of the University of Berlin.

A BOTANIC GARDEN has been established by the Belgian Government at Coquilhautville, Congo Free State. It will be called the Kew Gardens, and is expected to be of great importance to the rubber and other tropical industries.

THE Council of the Royal Geographical Society have decided to award the Murchison Grant for next year to Mr. John Coles, late Map Curator and Instructor to the Society, as an acknowledgment of his services to geography.

THE annual meeting of the Society of Chemical Industry will be held in the lecture theatre of the Royal Institution, Albemarle Street, on Wednesday, July 18, when the presidential address will be delivered, and the officers for the ensuing year appointed. The president-elect is Mr. J. W. Swan, F.R.S.

THE Council of the Sanitary Institute have arranged to hold a meeting in Paris from August 7 to 9, which will immediately precede the meeting of the International Congress of Hygiene and Demography, also to be held in Paris. The Société Française d'Hygiène have offered to the members of the Institute a cordial reception, and are providing a reception room, and making arrangements for special visits and excursions for the benefit of members attending.

A Public Health Congress will be held at Aberdeen from August 2 to 7, under the auspices of the Royal Institute of Public Health. Among the papers promised may be mentioned the following :—"Disinfection," by Prof. Delépine ; "Sewage," by Prof. Percy Frankland, F.R.S. ; and "The Origin and Treatment of Malarial Fever," by Dr. Patrick Manson. There will also be submitted and discussed a report on the inquiry made into the chemical and bacteriological condition of the air in the London Board Schools.

The Home Secretary has appointed a committee to inquire into the working of the method of identification of criminals by measurements and finger prints, and the administrative arrangements for carrying on the same, and to report whether any and what changes are desirable. The members of the committee are Lord Belper (Chairman), Mr. F. A. Bosanquet, Q.C., Common Serjeant, Mr. A. De Rutzen, Metropolitan Police Magistrate, and Mr. C. S. Murdoch, C.B., and Mr. C. E. Troup, C.B., of the Home Office, with Mr. C. Lubbock, of the Home Office, as secretary.

Among the Civil List pensions granted during the year ended on June 20, we notice the following :—Mr. Benjamin Harrison, in consideration of his researches in the subject of pre-historic flint implements, 26*l.* ; Mr. Thomas Whittaker, in consideration of his philosophical writings, 50*l.* ; Mr. Charles James Wollaston, in recognition of his services in connection with the introduction of submarine telegraphy, 100*l.* ; Mr. Robert Tucker, in consideration of his services in promoting the study of mathematics, 40*l.* ; Mrs. Eliza Arlidge, in consideration of the labours of her late husband, Dr. John Thomas Arlidge, in the cause of industrial hygiene, 50*l.* ; Miss Emily Victoria Biscoe, in consideration of the services rendered to Antarctic exploration by her late father, Captain John Biscoe, 30*l.*

Some molluscan remains found in a sandstone from the Malay Peninsula were described by Mr. R. Bullen Newton at the May meeting of the Malacological Society of London. The shells consist of Lamellibranch casts and impressions, many of them being sufficiently well defined to point conclusively to their Triassic origin. The most abundant genus represented is *myophoria*, so characteristic of the Trias period. *Chlamys valoniensis* also occurs, together with other bivalves. These fossils, the first recorded from this area of south-eastern Asia, were collected by Mr. H. F. Bellamy, and subsequently presented by him to the Geological Department of the British Museum. They were obtained from the Pahang Trunk Road, on the Lipis River.

The annual meeting of the Museums Association was opened at Canterbury on Monday. In an address, Dr. Henry Woodward, F.R.S., the president-elect, referred to his forty-two years' association with the British Museum and to the many changes and improvements which had taken place there during that period. He advocated the publication by the association of a handbook giving an account of every provincial museum throughout the country, with full particulars as to each, not only as to its officers, organisation, and its plan of arrangement, but also what were the chief features of its exhibits and especially any records concerning types and figured specimens preserved in its collections and any other particulars of general public interest. Papers upon museums and related subjects were subsequently read.

A new medical institute, having for its object the placing at the disposal of doctors the aids to diagnosis required in many forms of disease, has just been opened in Berlin. The institute will place at the disposal of the medical profession its laboratories, instruments and apparatus, and its officers will undertake the carrying out of special researches and examinations. It has departments devoted to the study of bacteriology, chemical microscopy, pathological anatomy, and physiology. To the last-named is attached a Röntgen ray room.

General Sir R. Murdoch Smith, K.C.M.G., Director-General of the Museum of Science and Art, Edinburgh, since 1885, died on July 3, after a brief illness. He was born in 1835, and was the executive officer with Sir Charles Newton's archæological expedition in Asia Minor in 1856-59. He explored the Cyrenaice and made successful explanations at Cyrene in 1860-61. Subsequently he became director-in-chief of the Government Indo-European Telegraph Department. He was the author of a "History of the Recent Discoveries at Cyrene," and of a "Handbook of Persian Art."

A permanent committee for the study of tuberculosis as a national scourge has been formed in Russia. The president is Prof. W. D. Scherwinsky, of Moscow. The committee, which has met twice a month since the beginning of April, has, says the *British Medical Journal*, drawn up for itself the following programme of work : (1) Reports on the communications made on tuberculosis to the Pirogoff Congress and other medical societies in Russia ; (2) reports of foreign congresses on tuberculosis ; (3) reports on tuberculosis as an infectious disease (diagnosis, etiology—heredity, individual predisposition, external influences, mode of diffusion, economic and social factors) ; (4) statistical data respecting tuberculosis in Russia ; (5) legislative measures and ordinances in regard to tuberculosis of human beings and beasts ; (6) sanatoria, koumiss establishments, &c. ; (7) the means actually in use, and which should be used, for the prevention of tuberculosis in the different provinces of Russia ; (8) tuberculosis in animals and its relation to the disease in human beings.

The new number of the *Geographical Journal* gives further particulars as to the preparations that have been made for the forthcoming National Antarctic Expedition. An executive officer, Lieut. Charles Royds, R.N., of H.M.S. *Crescent*, has been appointed ; and Mr. T. V. Hodgson (of the Marine Biological Station of Plymouth) and Dr. R. Koettlitz (of the Jackson-Harmsworth Expedition) will form part of the scientific staff, which Prof. Pollock (the holder of the chair of physics in the University of Sydney) will, it is stated, be invited to join. The name of the vessel used will be the *Discovery*. As was mentioned in our issue of May 31, the commanding officer of the expedition will be Lieut. R. F. Scott, R.N., and the leader of the scientific staff will be Prof. J. W. Gregory.

From information that has reached us from Mr. Rotch's Blue Hill Meteorological Observatory we learn that a kite used in the exploration of the air was on June 19 sent up to the height of 14,000 feet, thus exceeding the greatest height previously obtained there by 1440 feet. The temperature at this height was fifteen degrees below freezing point, the wind velocity was about twenty-five miles an hour from the north-east, and the air was extremely dry, although clouds floated above and below that level. The kites remained near the highest point from 5 to 8 p.m. On the way down the kites passed through a stratum of thin ragged clouds at the height of 1½ miles. These were moving with a velocity of about 30 miles an hour. At this time the wind at the observatory, about 600 feet above the general level of the surrounding country, had fallen to a calm. The highest point was reached with 4½ miles of music wire as a flying line supported by five kites attached to the line at intervals of about ¾ miles. The kites were Hargrave or box kites of the improved form devised at the observatory. They have curved flying surfaces modelled after the wings of a bird. The three kites nearest the top of the line had an area of between 60 and 70 square feet each, and the two others about 25 feet each. The total weight lifted into the air, including wire, instruments and kites, was about 130 lbs.

MR. E. G. GREEN, Government entomologist at the Botanic Gardens at Peradeniya, Ceylon, has recently been able to confirm by personal observation the web-spinning habits of the red ant (*Œcophila smaragdina*). He has seen ants actually holding larvæ in their mouths and utilising them as spinning machines. To find what would be done, some leaves which had been newly fastened together by the ants were purposely separated by Mr. Green. The edges of the leaves were quickly drawn together by the ants, and, about an hour later, small white grubs were seen being passed backwards and forwards across the gaps made in the walls of the shelter. Each grub (there were apparently only two of them) was held in the jaws of one of the worker ants, and its movements directed as required. A continuous thread of silk proceeded from the mouth of the larva, and was used to repair the damage. There were no larvæ amongst the occupants of the disturbed inclosures, and the grubs used for spinning were apparently obtained from a nest a short distance away, which probably accounts for the considerable time that elapsed before the rent was repaired.

THE temperature of the free air is the title of a paper communicated by Dr. Hergesell to Part V. of *Petermann's Geographische Mitteilungen*. We have frequently referred to the great importance of this subject and to the valuable work performed by Dr. Hergesell in organising ascents of manned and free (or unmanned) balloons, and in discussing the results of the observations obtained. In the present paper he collects and discusses the most recent materials, and deals especially with the daily range and the vertical decrease of temperature in the upper strata of the atmosphere. The observations show that even at a height of a few hundred metres, there is a very small diurnal range; at night-time it amounts, in some ascents, to only a few tenths of a degree, and in the day-time, at about 800 metres, to some 3° or 4° Centigrade, when solar radiation is unobstructed. On cloudy days, and in the mean values, the daily amplitude is much less. With respect to the vertical decrease of temperature, the results of thirty sets of observations show that in all levels up to 10,000 metres an extremely varying temperature obtains, according to the season of the year and the conditions of weather. The decrease at that height reached or exceeded 40° C. in all cases, but no fixed rule could be laid down as to the *regular* decrease with altitude.

A RECENT number of the *Scientific American* contains a very interesting account of the use of a diver for the collection of zoological specimens that has been made in the Bay of Avalon, California. A large double-ended surf boat, in which the pump was placed, was towed to the scene of operations and anchored securely, bow and stern. Besides this, a number of observation boats, with glass bottoms, were used, and through these every movement of the diver could be observed. As soon as the diver was ready to descend, a scoop-net and a spike were handed to him. Stepping down, round by round, he finally pushed off and slowly sank to the bottom in about twenty-five feet of water. Through the glass bottom of the observation boats every movement could be plainly seen, as the diver walked through the weed, parting it on each side with ease, and collecting such specimens as seemed desirable. In one walk he brought up angel fishes, star fishes, holothurians, echini, a number of large univalve shells, a living shark, and numbers of small shells. The result of two days' work demonstrated the value of this method of collecting specimens, as in using a dredge many of the most delicate forms were injured. Where a diver is used it is not necessary to take them from the water, the specimens being transferred in the water from the wire collecting-basket to a glass jar. The experiments are stated to have proved beyond question the value of the diver in work of this kind, as the ground covered was a veritable forest of macrosystis, in which groups of rocks were scattered, making work with a dredge impossible.

THE Russian steamer *Rurik* has arrived at Tromsö, from Spitsbergen, bringing news from the Russian expedition, which had wintered on the island for the measurement of an arc of the meridian. No news could be sent until now, because the carrier-pigeons which the expedition set free on Spitsbergen refused to fly southwards and obstinately returned to the wintering place. The *Rurik* probably brings in a full report from the chief of the expedition, Prof. Th. Tchernysheff, but from a telegram of the learned geologist, which was sent to the Academy of Sciences from Tromsö, we already learn that all members of the expedition were well. During the winter astronomical and physical observations were made according to the programme. Photographs were taken of auroræ and their spectra, and in the spring observations were made on Mount Keilhaus, at the signal-pillar of the meridian arc. South Spitsbergen was crossed several times. Akhmatoff made pendulum measurements on Mount Keilhaus. The state of ice was still unfavourable in Storfjord, and Prof. Tchernysheff's intention was to make more excursions and, leaving the "ice-breaker" at Storfjord, to try to reach the Swedish party at Seven Islands.

THE Transbaikalian Railway will be opened for traffic this month. It begins at Irkutsk, wherefrom a line, forty miles long, goes to Lake Baikal. There the train is placed on an ice-breaker-ferry and is transported to the Mysovskaya Station on the eastern shore of the lake, whence it runs 665 miles pas Verkhneudinsk, Chitá, and Nerchinsk (the town—not the mines) to Sryétensk. Steamers ply regularly during the summer from this little town down the Shilka and the Amur to its mouth. At the station Kaidalóva, near Chitá, begins the railway across Southern Transbaikalia, Mongolia, the Great Khingan Mountains and Manchuria, *viâ* Tsitsikar (on the Nonni) and Mukden, to Port Arthur. Work is busily carried on along this last line, building going on on several sections at once: in Transbaikalia, at Tsitsikar, and at the southern end of the line.

MESSRS. CADETT AND NEALL have sent us a sample of their X-ray paper. It is claimed for this material that a great reduction in exposure is effected as compared with the most rapid dry plates, about one-eighth of the usual exposure being all that is required. The paper has also the advantage over glass plates of freedom from risk of breakage, flexibility and consequent adaptability to the object to be photographed, and portability. The reason for paper of this description requiring so much less length of exposure than ordinary dry plates, is because less density is required for a reflecting surface to show structure than is required for a plate from which prints are required; consequently, with the X-ray paper, and using a 10-inch coil with a good tube, a good print of a hand can be obtained with about two seconds exposure; or, using an electrolytic break with the coil, with less than one second exposure.

AN ingenious machine for solving any algebraic equation of the form $px^{n} + px^{n_1} + p_2x^{n_2}$ + &c. = A, by an application of the principle of Archimedes, is described by M. Georges Meslin in the *Journal de Physique* for June. It consists of a beam balanced on a knife-blade from any point of which may be suspended a solid of revolution, and a series of such solids is provided, constructed in such a manner that in the solid of order *n* the volume cut off by a horizontal plane is proportional to the *n*th power of the distance of the horizontal plane from the lowest point. Thus for orders 1, 2, 3, the forms of the solids are a cylinder; a paraboloid of revolution, a cone. If the solid of order $n$ is suspended at a distance $p$ from the knife-blade, then when it is immersed to a depth $x$ in liquid, the moment of the resultant upward thrust of the fluid about the knife-edge is proportional to $px^n$. The operation of solving the equation consists in adjusting the weights at suitable distances, $p$, $p_1$, $p_2$ from the axis, and balancing them, then running water into a trough containing the solids until the fluid thrusts balance a weight A fixed at unit distance from the axis of the beam; when this is done the equation of moments takes the form of the given algebraic equation and $x$, the root of the equation is equal to the depth of immersion of the solids.

In the *Rendiconto del R. Istituto Lombardo*, xxxiii. 11, 12, Prof. Luigi Berzolari considers a generalisation of the problem enunciated by Tanturri, of discovering the number of conics meeting a given algebraic gauche curve in eight points. The generalisation consists in the problem of finding the number of conics meeting one or more given algebraic curves in $a$ points, passing through $b$ given points and touching $c$ given planes, where $a+2b+c=8$, and a number of results are given referring to the particular cases when one or more of the algebraic curves are straight lines.

Although it is now about sixty years since Moser published the results of his experiments on the action of light upon various surfaces as revealed by the condensation of vapours upon them, the character of the change produced by light still remains a mystery. Theories have been suggested, guesses have been made, but little or nothing has been proved. Major-General J. Waterhouse, I.S.C., has, during the last year, accumulated some additional interesting facts in connection with this subject. He fully confirms Moser's results as to the production of a change on the surface of metallic silver by exposure to light that can be demonstrated by the condensation of a vapour, such as mercury upon it. But he has gone further, and demonstrated the change by the deposition of silver from solution, after the manner of the development of an exposed wet collodion photographic plate. By some half hour's exposure in bright sunshine "printed out" images were obtained, that is, images visible without any subsequent application of a developer. General Waterhouse shows that these results are not due to pressure against the mask or stencil plate used, nor to the emanation of vapours from it, nor to heat. Usually blue light gives a much stronger effect than red, but in one experiment when the exposure was for three hours to bright sunshine, the effect was reversed, and the patches under red, orange and yellow glasses were developable, while those under the blue and violet glasses were not. But when the silver plate was heated to redness, quenched in dilute sulphuric acid, washed and dried, and the cut out design was also warmed before use, the effect produced by light was so small that it seems doubtful whether there was any effect at all. On the other hand, if the silver plate was exposed to the fumes of certain substances, especially nitric acid, it was rendered very much more sensitive. General Waterhouse, in his communication to the Royal Society, states that he hopes to continue the investigation this summer, and invites others to extend the observations that he has described.

In the course of the Cavendish Lecture on the "Application of Pathology to Surgery," recently delivered by Mr. H. T. Butlin, of St. Bartholomew's Hospital, to the West London Medico-Chirurgical Society, a good deal was said with reference to research work, especially in relation to pathology. In the course of the lecture the need was pointed out of two species of pathological laboratories for research—one for research in pure pathology, without any reference to its application, which "need not be attached, so far as its site is concerned, to any hospital. The other for research in applied pathology, the laboratory for inventors, must needs be attached to the hospital; and those who work in it should have the freest access to the wards, even if they are not in charge of special wards, and should have every opportunity of observing what is done there and in the operating rooms. In order that they may be thoroughly instructed in the science of pathology, they should be taken from among the workers in the laboratory of pure pathology, and should be selected on account of their special aptitude for the work of research and for the originality they have exhibited. They leave the school of discoverers and the science of pure pathology for the school of inventors and the science of applied pathology." After alluding to the advance that has been made during the last few years, the lecturer said: "Money and organisation are necessary if great results are to be secured. The laboratories for research in pure pathology are too small and too scattered, and insufficiently endowed. The laboratories in the hospitals, which ought to be devoted to applied pathology, are used for every kind of microscopical and bacteriological examination and for teaching, so that research is crowded out. And pathological chemistry, from which vast things are to be hoped in future, has taken no proper hold upon the town." An investment of funds for the advancement of medicine and surgery, something like the provisions made in certain industrial establishments in Germany for research, was needed, in the opinion of the lecturer, who had no doubt as to the advantage which would accrue from such a movement.

In No. 6 of the *Tufts College Studies* appears an important paper, by Mr. J. S. Kingsley, on the ossicles of the ear, which concludes with a suggestive discussion on the origin of mammals. In regard to the latter part of the subject, the author, as might be expected, attaches much importance to the fate of the quadrate bone of the lower vertebrates in mammals. And he arrives at the conclusion that the incus is mainly the representation of that element, although a portion of the latter may be included in the tympanic ring. It is further urged that the articulation of the lower jaw with the skull in mammals does not correspond with the same articulation in the lower vertebrates, but is entirely a new formation.

As regards the origin of mammals, Mr. Kingsley urges that the ancestral type must certainly have possessed a freely movable quadrate bone; from which he is led to conclude that the fixed suspensory arrangement of the lower jaw found in the chimæroid fishes, *Ceratodus*, and amphibians, is an acquired, and not a primitive, feature. Hence the fringe-finned fishes like *Polypterus* indicate the ancestral stock of the higher vertebrates. Reverting to mammals, it is shown that the anomodont reptiles of South Africa are far too specialised to have been the parent stock. From this and other inferences it is concluded that "no reptile has yet been found which will in any way fit the requirements for the ancestor of the mammalia; but that all known facts point rather to a line of descent from forms allied to the amphibia." There is, however, no amphibian type which conforms to the necessities of the situation, and it is accordingly necessary to go back to the common ancestor of the existing salamanders and cœcilians, and of the extinct labyrinthodonts or stegocephalians. In conclusion, it is stated that the ear-bones negative the view advanced by Mivart as to the egg-laying mammals having developed from a separate stock to that which gave origin to the other members of the class.

Memoir 4 of the Australian Museum, Sydney, deals with some of the Crustacea obtained during the trawling expedition of H.M.C.S. *Thetis* off the coast of New South Wales in the early part of 1898. Mr. T. Whitelegge, who has been entrusted with the description of this group, states that the collection of Crustaceans obtained during the cruise is remarkably rich in forms either new to science or to the fauna of New South Wales. Of the forty-five species recorded, twenty come under the latter category and nine under the former. But the present fasciculus applies only to the higher groups of the class, and when the lower forms are worked out a still larger proportion of novelties may be expected. The new types are figured in a well-executed series of plates.

IN its *Bulletin*, No. 180, the Michigan State Agricultural College Experiment Station sets an excellent example by calling attention to the noxious insects which have been most numerous during the past year in that district, and the best means for their destruction.

THE North London Natural History Society's syllabus for the period July to December has just reached us, and gives promise of an interesting session.

THE *Bibliotheca Mathematica*, iii. 1, contains a heliogravure portrait of the late Sophus Lie, together with a descriptive list of his papers by F. Engel, of Leipzig.

MESSRS. WILLIAMS AND NORGATE'S "Book Circular" for June has reached us. In it are to be found notes on new and forthcoming scientific publications, and a list of works on medicine, natural history, chemistry, physics, mathematics, &c.

WE have received Nos. 7 and 9 of *Scientia*. The former, by Dr. Denis Courtade, is entitled "L'Irritabilité dans la Série Animale," while the latter, by Dr. Pierre Bonnier, is called "L'Orientation," and deals with the notion and perception of space by animals, and the localisation of external objects.

THE conclusion of the series of articles on "South African Lepidoptera," by F. Barrett, in the *Entomologist's Monthly Magazine*, appears in the current issue of that periodical, and in it is contained the first instalment of an account of "An Excursion to Egypt, Palestine, Asia Minor, &c., in search of Aculeate Hymenoptera," from the pen of Rev. T. D. Morice.

THE July issue of "Climate, a quarterly journal of Health and Travel" contains several interesting articles, such as "The Art of Travelling" (an interview with Mrs. Bishop, the traveller), and "The Malaria Question," by the editor, in which a good deal of information is given in a compressed form.

IN the new number of "The Journal of the Royal Agricultural Society of England," Mr. W. E. Bear, in an article on "Fumigation for Insect Pests," passes in review the methods of fumigation that are or have been in use in various parts of the world, and the measure of success they have met with.

THE July number of *Knowledge* has as its leading article an account of the recent total solar eclipse, by Mr. E. W. Maunder. It is accompanied by a "process" reproduction of a full-page drawing of the corona, the work of Miss C. O. Stevens. Dr. W. Stanley Smith has commenced in the same periodical an interesting series of articles on Early Theories of Fermentation.

THE current number of *Science Gossip* contains the first of a series of "Geological Notes in Orange River Colony," from the pen of Mayor B. M. Skinner, which probably will appeal to a wider circle of readers just now than would have been the case had war not broken out. The present instalment deals with the country lying between Enslin and Bloemfontein.

THE *Agricultural Journal*, published by the Department of Agriculture, Cape of Good Hope, always contains many items of interest and value to the student of agriculture. The issue for May 10, which has just come to hand, contains, among other things, a good portion of the inaugural address on "The Bearings of Education and Science on Practical Agriculture." which was delivered by Prof. Somerville at Cambridge in November last.

THE Commissioner of Agriculture for the West Indies has issued a handy and useful pamphlet, entitled "Hints and Suggestions on Planting in Tobago." The greater portion deals with the subject of cacao culture, and is written by Mr. E. R. Smart, and revised by Mr. J. H. Hart and others. Short notes on other plants are from the pen of Sir R. B. Llewelyn, formerly Administrator of Tobago.

THE Yorkshire College, Leeds, on behalf of the East and West Ridings Joint Agricultural Council, will provide courses of instruction in the following subjects throughout the ensuing year:—Results of the Garforth and other experiments in the East and West Ridings; agriculture; veterinary hygiene; horticulture; and poultry keeping. A guide has been issued by the two bodies to experiments at the Manor Farm, Garforth, for the year 1900.

THE *Zambesi Mission Record* is a well-edited quarterly periodical, which contains not only reports of the religious and educational work done by the Catholic Mission under the auspices of which it is brought out, but also from time to time notes and articles on the natural history, botany and meteorology of the area traversed by the society; thus the issue for July contains notes on the weather and climate from observations taken at Bulawayo during 1899, and a lengthy contribution, entitled "By an African Pool," in which there is a good deal of popular science, appealing for the most part to the ornithologist. The latter article is illustrated by well-executed "process" blocks of photographs of specimens from the Albany Museum, Grahamstown.

RECENT successful attempts to prepare tubes and bulbs of fused quartz have led to a more detailed study of the thermal properties of this material. Its low coefficient of expansion and absolute unalterability at high temperatures would point to fused silica as an ideal material for air thermometry, and hence the observation by M. P. Villard in the current number of the *Comptes rendus*, that it resembles platinum in being permeable to hydrogen at high temperatures, is a disappointing one. A manometer connected to a pump and quartz tube, the latter being heated in a Bunsen burner to about 1000° C., shows a slowly increasing pressure, amounting in the course of a day to several centimetres of mercury, and on examination the gas proved to be nearly pure hydrogen. The same number contains a so a note by M. Dufour on the resistance of fused silica to sudden changes of temperature in which it is stated that quartz tubes, even although badly made, may be heated to any temperature and plunged into cold water without showing any signs of breaking.

IN the current number of the *Berichte* is a note by Dr. Vaubel on the phenyl derivative of diimide, NH : NH. This has been isolated in a simple manner from the products of reduction of diazoamidobenzene with zinc dust in alkaline solution. Phenyldiimide $C_6H_5.N : NH$ is an oily liquid of a pale yellowish colour, which can be distilled in steam, and possesses a strong odour of almond oil. Since it cannot be distilled with steam from an alkaline solution, it would appear to possess acid properties; it is very poisonous, and has no reducing action upon Fehling's solution. Contrary to expectation, it explodes neither on heating nor by shock. On account of its great stability towards oxidising agents, the author suggests the formula $C_6H_5.N \vdots NH$ as being the most probable.

The additions to the Zoological Society's Gardens during the past week include two Tigers (*Felis tigris*, ♂, ♀) from India, presented by H.H. the Maharani Regent of Mysore; a Black-eared Marmoset (*Hapale jacchus*) from South-east Brazil, presented by Mrs. G. L. Bagnell; a Pine Marten (*Mustela martes*), British, presented by Mr. C. G. Beale; a Common Squirrel (*Sciurus vulgaris*), British, presented by Mr. Cecil Slade; a Yellow-cheeked Amazon (*Chrysotis autumnalis*) from Honduras, presented by Mr. S. Hankings; two Crimson-crowned Weaver Birds (*Euplectes flammiceps*) from West Africa, presented by Mrs. Charles Green; a Sharp-nosed Crocodile (*Crocodilus cataphractus*) from West Africa, presented by Mr. J. A. Robb; a Four-lined Snake (*Coluber quatuorlineatus*), European, presented by Mr. W. R. Temple; four Natterjack Toads (*Bufo calamita*), European, presented by Mr. Stanley S. Flower; two Great Wallaroos (*Macropus robustus*, ♂, ♀) from South Australia, three Wrinkled Terrapins (*Chrysemys scripta rugosa*) from the West Indies, deposited; an Adanson's Sternothere (*Sternothoerus adansoni*), a Common Chamæleon (*Chamaeleon vulgaris*) from the Soudan, received in exchange; a Burrhel Wild Sheep (*Ovis burrhel*), two Black-backed Gulls (*Larus marinus*), a Herring Gull (*Larus argentatus*), bred in the Gardens.

Erratum.—We are asked to state that in the report of Prof. S. Young's paper, read before the Physical Society on June 22, on the Law of Cailletet and Mathias, the words "1 per cent." (p. 215, col. 1, line 3) should be "0·1 per cent." The 0 was omitted from the report sent to us.

## OUR ASTRONOMICAL COLUMN.

Comet Giacobini (1900 *a*).—Several observations have been made of this comet since its conjunction with the sun, but it is reported as faint. The following positions are an abridgment from the Ephemeris by Herr Ristenpart in *Astronomische Nachrichten*, No. 3636.

*Ephemeris for* 12*h. Berlin Mean Time.*

| 1900. | | R.A. h. m. s. | | Decl. ° ' |
|---|---|---|---|---|
| July 12 | ... | 22 29 5 | ... | +46 25·9 |
| 14 | ... | 12 29 | ... | 46 50·9 |
| 16 | .. | 21 55 5 | ... | 47 5·1 |
| 18 | ... | 37 4 | ... | 47 7·1 |
| 20 | ... | 18 42 | ... | 46 55 9 |
| 22 | ... | 21 0 16 | ... | 46 30·8 |
| 24 | ... | 20 42 2 | ... | 45 51·8 |
| 26 | .. | 24 19 | ... | 45 0·0 |
| 28 | ... | 20 7 20 | ... | 43 56·4 |
| 30 | ... | 19 51 16 | ... | +42 42·4 |

The comet attains its maximum north declination on the 18th, to the north-west of α Cygni, afterwards travelling in a south-westerly direction through Cygnus and Lyra.

## WALTER PERCY SLADEN.

By the death of Walter Percy Sladen, the world has lost one of the most lovable of men, and science an earnest devotee—a worker content to spare no effort could he but discover the truth.

Sladen was born on June 30, 1849, at Meerelough House, near Halifax, Yorkshire, and was educated at Hipperholme Grammar School, and afterwards at Marlborough under Dean Bradley. He came of an old Yorkshire family, who have been much respected for many generations; and ease and refinement of manner were among his marked characteristics, while the charm of his address endeared him to all with whom he came in contact.

He never attended a regular academic course of instruction in the branch of science in which he became eminent; his elementary training was self-acquired, and his leaning towards zoology innate. The definitive choice of the Echinoderma as the object of his life's work was of his own seeking, after much consideration; and in this he showed great force of character and a power of self-reliance which there was reason earlier to believe he possessed, for even before he entered Marlborough he evinced an unusual predisposition towards science, in founding for his boy friends a scientific society devoted more especially to the study of astronomy, in connection with which he became known among them as the "Astronomer Royal." Little did he think that he would in later life become for ten years a secretary of a leading scientific society, and that for eighteen he would conduct the affairs of a zoological research committee, as he did in his capacity as Secretary to the British Association Table of the Naples Station.

Sladen's scientific work, so far as his published memoirs and papers are concerned, extended over a period of seventeen years, 1877 to 1893. Of these there are thirty-four in all—twenty-one from his own hand, thirteen in conjunction with his intimate friend and adviser, the late Prof. Martin Duncan. Beyond these there stand to his record certain bibliographical notices and miscellanea. Of the thirty-four published works, fifteen of which he was sole, and four of which he was joint author, deal with the starfishes; and of the remaining fifteen, nine were conjoint, and devoted, with the exception of two, to fossil forms. Conspicuous among these are reports upon the collections made by the Geological Survey of India; and among those which he alone produced are Parts i. and ii. of the second volume of the Palæontographical Society's Memoirs on the Fossil Echinodermata, which were his last published works. They deal with the Cretaceous Asteroids, and appeared in the Society's volumes for 1890 and 1893. His first three papers deal with the remarkable creature *Astrophiura*, whose generic name is self-explanatory. The first, a brief description, was published in the *Proceedings of the Royal Society* for 1878; the other two, each containing a Latin diagnosis, in the *Zoologischer Anzeiger* and *Annals and Magazine of Natural History*, the year following. His remaining papers appeared in the *Annals* and the *Journal of the Linnean Society*, the publications of the Royal Society of Edinburgh, and elsewhere. They mostly deal with whole collections, and include reports on those made in the Arctic Region in 1875–1876, on those of the *Alert*, *Knight Errant* and *Triton*, as also those made in the Faroe Channel, the Korean Sea, and the Mergui Archipelago. In each Sladen produced good results, as in the discovery of genera such as *Micraster* and *Rhegaster*; and what more natural, therefore, than that he should have been entrusted with the working out of the Asteroids collected by H.M.S. *Challenger*, the report upon which was the crowning achievement of his life.

This magnificent work of 900 pp., with its accompanying atlas of 118 plates, ranks among the most masterly and exhaustive of the *Challenger* volumes. Before taking it seriously in hand, Sladen visited every museum in Europe (with one exception) which was known to contain starfishes of importance; and, as pointed out by the editor in its preface, it is a monograph of the whole group. The labour involved in its production was prodigious; and its interest is enhanced by the fact that the bulk of it was written between the hours of 9 p.m. and those of early morning, often after a day's occupation with other affairs. The extension of the family Pterasteridæ and the great addition to our knowledge of the deep-sea forms are its most salient characters; but we know not which to admire most, the body of the work, with its laborious descriptions of individual forms, or the supplemental part, in which there is given a list of every known species, with a record of its bathymetric distribution. Elementary student and expert stand alike indebted to him for this monumental work, indispensable to progress in the knowledge of the subject with which it deals. Generic names like *Benthaster* and *Marsipaster* are sufficiently significant in themselves. Proceeding to classification, Sladen made good use of the marginal and ambulacral plates, and his subdivision into the sub-classes *Euasteroidea* and *Palaeasteroidea*, with the ordinal divisions to which he was led, has withstood the test of time and become the adopted classification of the better text-books, as for example those of Lang and Gregory. In this his influence on the progress of science will live, and it is a matter of profound gratification that only a short time before his death he gave expression to the satisfaction this recognition afforded him.

Beyond this magnificent work and those papers more or less immediately associated with it, wholly taxonomic, Sladen produced others of a physiological and developmental order, as for example his Naples Station paper, on the structure and functions of the pedicellariæ, and that announcing his discovery of the "cribriform organ," and his papers on the apical plates of the Astrophiuroids, in which he was obviously in agreement with his friend, the late Dr. Herbert Carpenter, in the belief in a stalked ancestry of these. It has been said of his taxonomic work that his descriptions are protracted, and that he deals with specimens as species. There is, however, no reason to believe that he was using the term species in any but a purely conventional sense, without necessarily implying any fixed inter-relationships; and his painstaking accuracy of description was the outcome of an excessive honesty of purpose and desire for thoroughness, in which he was altogether exemplary. There never lived a man with a truer sense of honour.

Some ten years ago Sladen had a bad attack of influenza, followed at intervals by several similar visitations, which unfitted him for serious scientific work, but he always hoped to get better and to take it up again. The last winter was passed in Devonshire with very beneficial results, and he might be said to have been in his usual health when two months ago he started with his wife for Rome. But the wish to return to work was not to be fulfilled; after spending six weeks in Rome he journeyed to Florence, and there after a week of rather active sightseeing, on June 11, he was taken with a fainting fit, and though he quickly recovered consciousness and declared his intention of going to Como that very night, within half an hour he passed away by failure of the heart's action.

He was a Fellow of the Linnean, Zoological, and Geological Societies; for ten years Zoologic Secretary, and later a Vice-President of the former. In his secretarial capacity his genial nature found full sway, and his encouraging attitude to the younger men with whom he came in contact will ever be remembered. As a boy at school he was the captain wrestler. He was a good shot, though never a sportsman or member of a rifle corps, but he belonged to a private Guerilla Club in Yorkshire, of which he was sometime secretary.

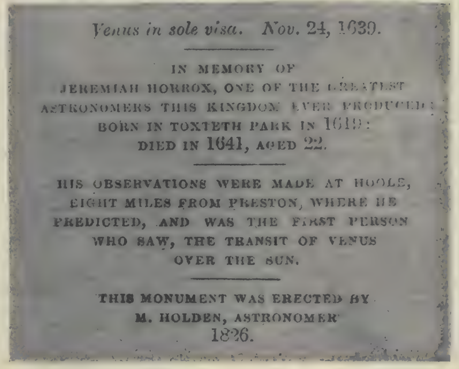
In 1890 Sladen married Constance, elder daughter of the late Dr. W. C. Anderson, of York; and about two years ago he inherited from an uncle the estate of Northbrook, near Exeter, and there he has been laid to rest. It will be remembered that he recently gave the sum of 2000*l*. to insure the lives of the Yeomanry and Volunteers of his county going to the front in the Boer campaign; and this is but one among many of his generous acts, the majority of which are known only to the recipients. A loving husband, a trustworthy friend, whose advice was always sound, a keen sympathiser with suffering humanity, he has passed from us; but his memory and tender-loving influence for good will endure.

Among his scientific effects are a large library and some zoological collections of great value. Sladen had always a taste for old books, and one of his last expeditions was to a monastery at Subiaco, to examine some ninth century MSS. there preserved, and he had collected a goodly number of ancient MSS. and examples of early printing. His collection of Echinoderm literature is very complete; while, as to material, he leaves the collections of his friend, the late Herbert Carpenter, rich in Crinoids and other rare animal forms, which include, as a separate historic possession, the materials which formed the basis of the elder Carpenter's book on the microscope. These he purchased. There were also in his possession at the time of death a large series of Cretaceous Echinoderms, upon which he was contemplating a renewal of his Palæontographical Society's work; and the collection of Astrophiuroids of the *Albatross*, entrusted to his hands by Prof. A. Agassiz. There accompanied these a series of superb coloured drawings from the life, like those already published for the Holothuroidea of the expedition; and the very day of his death there reached him a letter from the same distinguished explorer, offering him the materials of his recent Australian cruise. It was Sladen's intention to have returned to these rich possessions; and we could desire no more fitting memorial to his work than that it might be possible to find and train a competent zoologist to continue that which he has left thus unfinished, on the lines on which he would have laboured, and to hand it down to posterity a completed record in his name.

G. B. H.

## *JEREMIAH HORROCKS AND THE TRANSIT OF VENUS.*

WE are indebted to the *Journal* of the Leeds Astronomical Society for 1899, which contains an interesting paper by Mr. A. Dodgson, on the life and work of the illustrious young astronomer, Jeremiah Horrocks. This worthy was born in 1619, 281 years ago, in the reign of James I., at Toxteth, three miles from Liverpool. He received his early education there, but on reaching the age of fourteen, he entered as "sizar" at Emmanuel College, Cambridge. At seventeen he was enabled to become tutor at Toxteth, and two years later, *i.e.* in his nineteenth year, he was appointed curate at Hoole, near Preston. Soon after this he made his memorable astronomical observation of Venus, and only two years later was dead. The life of the young man at Cambridge, as traced by Mr. Dodgson, was one of persistent industry. Imbued at an early age with a love of studying natural phenomena, he was hampered at the outset by the absence of instruction in mathematics and the scarcity of books. This difficulty of getting philosophical and scientific works is clearly shown by the fact that of the thirty-two volumes he possessed later, not one was published in England or written by an Englishman. Lansberg's works he could not make agree with his own observations, and later, having obtained those of Kepler through the advice of his friend Crabtree, of Manchester, he found that even they needed many corrections. His first results in astronomical research were in elucidation of the lunar theory. Sir Isaac Newton confirms that he was the first to state the ellipticity of the moon's orbit; he also stated the causes of "evection" and "annual equation." The experiment of the circular pendulum for illustrating the action of a central force is also due to him. Most interesting, however, is his successful prediction of the transit of Venus in November, 1639. Kepler had stated that the two next transits would occur in 1631 and 1761, but Horrocks found, during his revision of the tables he had in use, that another would take place, the slight



*Venus in sole visa.* Nov. 24, 1639.

IN MEMORY OF
JEREMIAH HORROX, ONE OF THE GREATEST
ASTRONOMERS THIS KINGDOM EVER PRODUCED:
BORN IN TOXTETH PARK IN 1619:
DIED IN 1641, AGED 22.

HIS OBSERVATIONS WERE MADE AT HOOLE,
EIGHT MILES FROM PRESTON, WHERE HE
PREDICTED, AND WAS THE FIRST PERSON
WHO SAW, THE TRANSIT OF VENUS
OVER THE SUN.

THIS MONUMENT WAS ERECTED BY
M. HOLDEN, ASTRONOMER
1826.

errors in Kepler's tables probably accounting for his omitting it. Horrocks made all preparations for observing the phenomenon, arranging the image projected from his telescope (which had cost him half-a-crown) on a sheet of white paper having a circle six inches in diameter traced on it, the circumference being divided into degrees. He watched from sunrise to nine o'clock, and from ten until noon. Resuming his labour again shortly after three, he was overjoyed to find a round black spot just within the limb of the sun, at the internal contact. During some thirty minutes he was enabled to make many observations, which he considered very successful. Besides these definite scientific achievements, he wrote upon many different phenomena connected with the solar system, including the motions of Jupiter, Saturn, and various comets. The illustration on p. 257, reproduced from Mr. Dodgson's paper, shows Carr's house at Hoole, where Horrocks made his transit observation, and also the monumental tablet erected in 1826 to his memory in Hoole Church.

---

## JUBILEE OF THE IMPERIAL GEOLOGICAL INSTITUTE OF VIENNA.

TO celebrate the fiftieth anniversary of the foundation of the Imperial Geological Institute of Vienna, a jubilee meeting was held on June 9 in the Great Hall of the Institute under the presidency of its present director, Hofrath Guido Stache. The meeting was attended by a number of high Government officials, geologists, and representatives of national industries and scientific associations.

The director having welcomed the guests, speeches of congratulation were delivered by his Excellency the Minister for Spiritual and Educational Affairs, Dr. W. Ritter von Hartel, his Excellency the Minister for Railways, Dr. H. Ritter von Wittek, and the Mayor of Vienna, Dr. C. Lueger. These were succeeded by the following representatives of scientific institutions and industries, who presented addresses: Geheimrath von Richthofen, conveying the good wishes of the Prussian Royal Academy of Sciences, the Gesellschaft für Erdkunde, and the German Geological Society; Prof. Dr. Beyschlag, for the Royal Prussian Geological Institution and the Berg Akademie of Berlin; Geheimrath Dr. Lepsius, for the Grand-ducal Institute of Hesse and the Upper Rhine Geological Society at Darmstadt; Prof. Dr. E. Naumann, for the Senckenberg Natural Science Society of Frankfurt a-M.; Sectionsrath Boeck, for the Hungarian Geological Institution and the Hungarian Geological Society; and Chief Geologist Pethö, for the Natural Science Association of Buda-Pesth.

Among Austrian representatives there were: Prof. E. Suess, as President of the Imperial Academy of Sciences; Prof. L. Szajnocha, for the Cracow Academy; Prof. Woldrich, for the Bohemian Francis Joseph Academy; Hofrath Steindachner, for the Court Museum of Natural History; his Excellency Field-Marshal Ritter von Steeb, as Commandant of the Military Geographical Institute; Rector Zeisel, for the Agricultural College; Hofrath Juraschek, for the Central Statistical Commission; Prof. Doelter, for the Steiermark Scientific Society; and Vice-President Straberger, for the Francisco-Carolineum at Linz.

The good wishes of the Lower Austrian Chamber of Commerce were presented by the President of the Northern Railway, Hofrath Jeitteles, and the congratulations of societies for the advancement of allied sciences were tendered by Custos Marenzeller, Freiherr von Poche, Hofrath Toula, Freiherr von Andrian, and Councillor Karrer. In conclusion, the Chairman read those parts of the Jubilee Report which referred to the advancement of the Institute by the Emperor and the Government.

Among the 264 messages of congratulation received the following are specially mentioned: from the Geological Survey of Great Britain and Ireland, the Geological Society and the Iron and Steel Institute in London, the Smithsonian Institution and the United States Coast and Geodetic Survey in Washington, the American Philosophical Society in Philadelphia, and the Cincinnati Society of Natural History. Also those of the Imperial Russian Academy of Sciences, the Russian Geological Committee, and the Imperial Russian Mineralogical Society at St. Petersburg; the Naturalists' Society of Moscow, the Royal Swedish Academies at Stockholm and Upsala, the Academia dei Lincei and the Ufficio Geologico in Rome, the Science Academies of Naples and Turin, the Belgian Geological Society, the Royal Academy of Amsterdam, and scientific associations and institutions at Hallé, Dresden, Leipzig, Breslau and Göttingen.

The Institute, or Geologische Reichsanstalt, was founded in 1849 by the then Minister of Mines and Agriculture, von Thinnfeld, with the object of working out the geology of the whole empire, collecting and arranging the material, and publishing the results in maps and memoirs. Haidinger was its first director, and his chief geologist was Freiherr von Hauer, who was appointed director on Haidinger's death in 1866. In those early days the position of the Institute was not by any means secure. In 1859 an attempt was made to abolish it as a separate institution and to incorporate it with the mathematical and natural science section of the Imperial Academy of Sciences. But the proposed change failed to obtain the approval of the Reichsrath.

Between 1867 and 1871, under von Hauer's direction, a geological map of the Austro-Hungarian Monarchy was published, to a scale of 1 in 576,000. Under the supervision of the present director, Hofrath G. Stache, the publication of a series of detail maps has been commenced. The publications of the Institute comprise the annual *Jahrbuch*, which has now reached its fiftieth volume, the *Verhandlungen*, and the *Abhandlungen*. The latter are in 4to, and up to the present they have an aggregate of 7000 pages and 950 lithographic plates. Besides, explanatory letterpress is issued with each section of the new detailed geological map drawn to a scale of 1 in 75,000.

A chemical laboratory is attached to the Institute, which undertakes geological and industrial analyses. This laboratory was suppressed for several years, owing, it is said, to the overshadowing influence of another laboratory connected with the Vienna Academy of Sciences (see Dr. Tietze's "Life of Franz von Hauer," Vienna, 1900).

The Institute possesses extensive geological and mineralogical collections, chiefly from Austrian and Hungarian districts. These are exhibited in twenty-one rooms, some of which are really halls of great architectural beauty. The library contains over 40,000 volumes.

The Reichsanstalt is under the supervision of the Minister for Spiritual and Educational Affairs. Its annual income is 18,000*l*. Its staff numbers twenty persons, twelve of whom are employed in the Geological Survey.

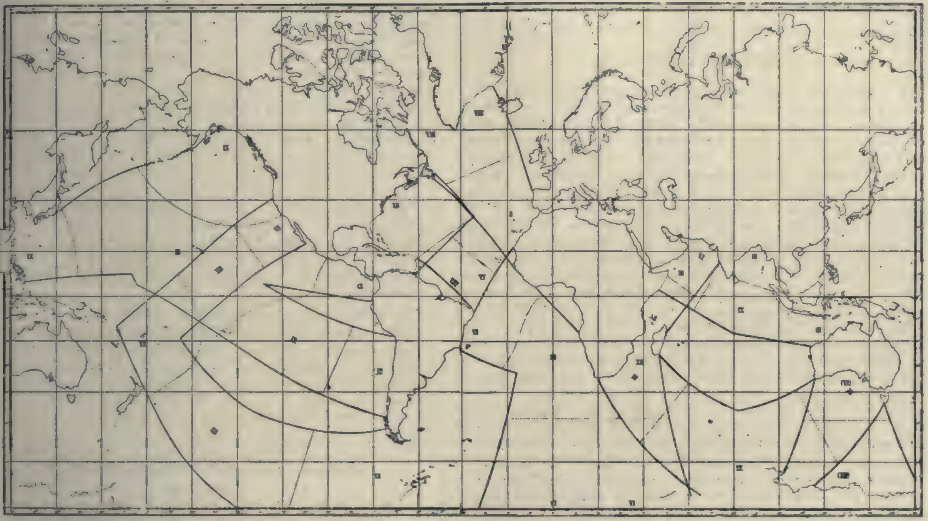
---

## A PARTIAL EXPLANATION OF SOME OF THE PRINCIPAL OCEAN TIDES.

AT the meeting of the U.S. National Academy of Sciences on April 19, a paper bearing the above title was read by Mr. R. A. Harris, of the United States Coast and Geodetic Survey. An abstract summarising the chief results arrived at has been published by the Academy: the full memoir is to be issued as an Appendix to the Annual Report of the Survey for 1899–1900. The abstract is too short to allow of critical examination of the methods employed in these inquiries, but some of the conclusions stated are very significant and important.

Mr. Harris enunciates the fundamental proposition of his investigation in the following terms: "Considering the actual distribution of land and water, a few computations upon hypothetical cases will suffice to convince one that as a rule the ocean tides, as we know them, are so great that they can be produced only by successive actions of the tidal forces upon oscillating systems, each having, as free period, approximately the period of the forces, and each perfect enough to preserve the general character of its motion during several such periods were the forces to cease their action . . . having once for all constructed a set of force diagrams for the various latitudes, we have only to discover those regions which have a free period of oscillation about equal to the period of the forces, and to then ascertain at what time the particles should be at elongation in their nearly rectilinear paths."

The main idea underlying this proposition is not altogether new, the novelty in the present paper is rather an attempt to locate and define areas which seem to account for the principal ocean tides, due regard being had to the difficulties arising from irregularities in the natural boundaries of such areas where such exist, or from the absence of natural boundaries. Each *oscillating area* is one of comparatively simple form, of which the free period of oscillation, supposing its boundaries all rigid, would not differ much from twelve lunar hours, and the forces are connected with the dominant ocean tides by applying to such an area, or to a system of such areas, the rule that "if to the particles of water in a given oscillating system, each area of uniform depth, and wherein the resistances are proportional to the velocities of the particles, a series of simple harmonic forces having for period the free period of the body of water be applied and a permanent state established, then must the time of elongation be simultaneous with the time when the virtual work of the external periodic forces upon the system becomes zero." Applying this rule, by means of the tidal-force diagrams the time can be found when "the aggregate of the elementary masses, each multiplied by the intensity of the tidal force in the direction of the displacement of the element, and again by a quantity proportional to the value of the maximum displacement (since the oscillation is harmonic), is zero" : this is the time of high or low water. The results of this method appear at once in a few simple cases: thus in an east-and-west canal half a wave-length long it is high water at the east end at the component hour 0 or 12, the time meridian being understood to be the meridian of the middle point of the canal; in a meridional canal one wave-length long, whose centre lies between 45° south and 45° north latitude, it is high water at both ends at the component hour 9; if the centre lies beyond these limits, the component hour of high water at the ends is 3.



Before laying down the oscillating areas, Mr. Harris gives a number of lemmas which have to be borne in mind as modifying the motions discussed. To quote one example: "Suppose a stationary oscillation to exist in a canal communicating with a tided sea; let the length of the canal lie between 0 and $\frac{1}{4}\lambda$, then at the time of high water outside it is high water throughout the canal (*e.g.* many Alaskan canals). If the length lie between $\frac{1}{4}\lambda$ and $\frac{3}{4}\lambda$, it is low water for a distance of $\frac{1}{4}\lambda$ from the head at the time it is high water outside (*e.g.* Irish Sea, node at Courtown; English Channel, node at Christchurch). If the length be equal, or nearly equal, to $\frac{1}{4}\lambda$, then the horizontal motion at the mouth, instead of the vertical motion, determines the time of tide within; this tide will be three hours later than the tide outside (*e.g.* the Gulf of Maine).

The systems supposed to account for the principal semi-daily movements of the oceans are outlined on the chart which we reproduce in a reduced form; the Roman numerals indicate the cotidal hours. The main systems are seven in number: (1) North Atlantic, (2) South Atlantic, (3) North Pacific, (4) South Pacific, (5) North Indian, (6) South Indian, (7) South Australian (solar).

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Applications are invited for the new Wykeham professorship of physics, referred to in a note on May 24 (p. 91). The election will take place in November, and applications must reach the Registrar not later than October 24. The following particulars are given in the *University Gazette*:—The subjects on which the professor will chiefly lecture and give instruction will be electricity and magnetism. The professor will have the charge of any laboratory which the University may assign to him. It is expected that rooms, now otherwise occupied, will be assigned to the professor for a laboratory in the course of the year 1901; 700*l.* will be appropriated to fitting up the laboratory, and provision has been made for spending 250*l.* a year for the first two years on assistance and maintenance. As soon as the professor is elected, he will be entitled to be admitted to a Fellowship at New College of the annual value of 200*l.* In addition, from January 1, 1901, he will receive from New College (1) an annual payment of 200*l.*; and (2) a further annual payment of 100*l.* so long as the College has funds available for the purpose. It is anticipated that this further payment will be paid for not less than twelve or thirteen years.

PROF. MCCALL ANDERSON, Professor of Clinical Medicine in the University of Glasgow, has been appointed to the chair of Systematic Medicine in the same University, in place of Sir W. Gairdner, resigned.

THE war in South Africa has raised many questions of great national importance which are fortunately receiving the attention of many thoughtful people. Prominent among these subjects of discussion is the urgent problem of how to obtain an improved supply of suitably educated officers, which was recently dealt with in a paper read by the Headmaster of Eton at the Royal United Service Institution. Dr. Warre maintains that a wider diffusion of the knowledge of the *elementa* of military science among the educated youth of the nation would tend, not only to raise the standard of military knowledge in the Army and Auxiliary Forces, but to improve the methods of communicating that knowledge to the rising generation, an indirectly widen the area from which a supply of well-educated officers may constantly be drawn. The great majority of the headmasters of our public schools agree with Dr. Warre, and he has drawn up, at the request of the War Office, a memorandum in which he advocates the need for a new Act of Parliament, the tenor of which should be "that all persons *in* *statu pupillari* in public secondary schools above the age of fifteen, able and willing to bear arms, should be enrolled for the purpose of instruction in drill, manœuvre, and the use of arms." At the same time the paper makes it quite clear that the Headmaster of Eton thinks mere proficiency in drill is not sufficient —at every step the boy must be taught the reason of everything he is called upon to do, and throughout his training his intelligence must be carefully and steadily developed. Approaching the same question from another point of view, Prof. Armstrong, in a letter to the *Times*, maintains that no amount of mere military training given in schools, or subsequently, will ensure the necessary improvement in our officers, unless the intelligence of boys is more satisfactorily developed in the early years at schools—an end which can best be secured by an adequate training in the scientific method. It may fairly be surmised that the Headmaster of Eton is quite in agreement with Dr. Armstrong as to the paramount importance of early teaching, and that both are equally anxious that intelligent citizens should somehow be produced. Of the value of a familiarity with the methods of science it is here unnecessary to say anything, but it would certainly appear that both contentions are right. What is wanted is Dr. Warre's intelligent military training for public school boys who have all had the advantage of a training in the scientific method for which Dr. Armstrong pleads.

## SCIENTIFIC SERIALS.

*Transactions of the American Mathematical Society*, vol. i. No. 2, April.—On the metric geometry of the plane $n$-line, by F. Morley. The relations which $n$-lines of a plane exhibit, when considered in relation to the circular points, have not received, in Prof. Morley's opinion, systematic attention since the important memoirs by Clifford, on Miquel's theorem ("Works," p. 51), and by Kantor (*Wiener Berichte*, vols. lxxvi. and lxxviii.). He applies certain notions which are fundamental in the geometric treatment of the theory of functions, and especially the notion of mapping. The paper is an interesting extension of Clifford's chain, and adds many curious results.—On relative motion, by A. S. Chessin. A memoir extending to 54 pages. The theory developed in it originated in a memoir by Bour in 1863 (*Journal de Liouville*, Ser. 2, vol. viii.). It deals mainly with the so-called "second form" of differential equations of Lagrange, and with the canonical system of differential equations of Hamilton-Jacobi. The first part of the paper deals only with the *theory* of relative motion. The differential equations are derived from one fundamental principle embodied in the so-called "theorem of Coriolis." This enables the author, not only to write down the differential equations of relative motion *immediately* from the corresponding equations of absolute motion, but to obtain equations *as general as those known for absolute motion*. In this first part there are eleven chapters. The second part (promised) is to contain applications of the theory. Among the problems to be discussed is the problem of Foucault's pendulum when the oscillations are not infinitely small, and the problem of Foucault's top, which Gilbert was unable to solve (sur l'application de la méthode de Lagrange à divers problèmes de mouvement relatif). The two problems, our author states, can be easily solved by the theory and formulas given in this first part.—Plane cubics and irrational covariant cubics, by H. S. White.—The paper considers cubics invariant under *partial* transformation by covariants (2, 2), and those invariant under *complete* transformation by covariants (3, 3). There remain for further treatment the two sets of conics invariant under the third transformation (2, 2), and invariant curves of order higher than the third (*cf.* the author's paper in No. 1). The new covariant cubics are eight in number, all of the type called equianharmonics.—A purely geometric representation of all points in the projective plane, by J. L. Coolidge. After some definitions, the writer gives a representation of all points in a real line by lines in a real plane, and then extends the representation so as to include all points in a real plane, noticing in particular those systems of lines which represent points on an imaginary line. He then takes up the subject of chains of points, showing their application to the general theory of projectivity. Finally, he glances briefly at the system of lines which represent points on a real conic, and concludes with remarks as to other possible solutions of the problem and its extension to three dimensions.—The decomposition of the general collineation of space into three skew reflections, by E. B. Wilson. The paper discusses the question, "Is it possible to decompose the general collineations of space into the product of a number of skew reflections; and if so, what is the least number of skew reflections involved in such a decomposition?"—A new method of determining the differential parameters and invariants of quadratic differential quantics, by H. Maschke, exhibits in a preliminary way a symbolic method in close analogy with the symbolism used in the algebraic theory of invariants, for the construction and investigation of invariants of quadratic differential quantics.—On the extension of Delaunay's method in the lunar theory to the general problem of planetary motion, by G. W. Hill, shows that the tediousness of Delaunay's method disappears when the greatest generality is given to the procedure.—Mr. J. E. Campbell writes on the types of linear partial differential equations of the second order in three independent variables which are unaltered by the transformations of a continuous group.

*Bulletin of the American Mathematical Society*, June.—Prof. Cole furnishes an account of the *Proceedings* at the New York April meeting of the Society, and abstracts several of the papers read; and Prof. Holgate performs a like office for the April meeting of the Chicago section of the Society.—J. G. Hagen gives a short sketch of the history of the extensions of the calculus. The abstract is confined to those theories that are in close relation to the infinitesimal calculus and the theory of functions, and excludes geometrical methods and methods of demonstration. To name one or two points discussed, they are Cauchy's "Calcul des Résidues," Schell's "Quotial and Instaural," the exponential function of higher order, the logarithmic methods of Bergbohm and Oltramare, and the extension of the calculus of finite differences.—Reviews are given of Burnside's "Theory of Groups," by Dr. G. A. Miller; of D'Ocagne's "Traité de Nomographie," by Prof. Morley; of Barton's "Theory of Equations," by J. Maclay; of Rice's "Theory and Practice of Interpolation," by Prof. E. W. Brown; of Von Braunmühl's "History of Trigonometry," by Prof. Cajori; of M. Boyer's interesting "Histoire du Mathématiques," by the same writer; and of Frischauf's "Vorlesungen über Kreis- und Kugel-Functionen-Reihen," by W. B. Ford.—Varied information is supplied in the "Notes" and "New Publications."

The numbers of the *Journal of Botany* for May, June, and July are almost entirely occupied by articles descriptive of new species, or relating to the geographical distribution of plants, chiefly in the British Islands. Mr. H. N. Dixon records the detection of an addition to British mosses in *Amblystegium compactum*, and Mr. S. M. Macvicar an addition to British Hepaticæ, in *Pellia neesiana*.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Chemical Society**, June 21.—Prof. Thorpe, President, in the chair. The following papers were read.—Researches on morphine, I., by S. B. Schryver and F. H. Lees. Morphine readily exchanges an alcoholic hydroxyl group for halogen, yielding the bases chloromorphide, $C_{17}H_{18}O_2NCl$, and bromomorphide; when heated with water these substances give isomorphine, $C_{17}H_{19}O_3N$, and on reduction chloromorphine yields desoxymorphine hydrochloride $(C_{17}H_{19}O_2N,HCl)_2.3H_2O$. These four new bases are not narcotics.—On the oxime of mesoxamide and some allied compounds, by M. A. Whiteley. Nitrosyl chloride converts malonamide into the isonitroso-derivative, $CONH_2.C(NOH).CONH_2$; nitrous acid converts the latter into a pseudonitrole, $CONH_2.C(NO)(NO_2).CONH_2$, and hydriodic acid reduces it to aminomalonamide,

$$CONH_2.CH(NH_2).CONH_2.$$

—On dimethyldiacetylacetone, tetramethylpyrone and orcinol derivatives from diacetylacetone, by J. N. Collie and B. D. Steele. Disodiodimethylpyrone and methyl iodide react, giving dimethyldiacetylacetone, $C_7H_8O_3(CH_3)_2$, which is converted into tetramethylpyrone, $C_7H_6O_2(CH_3)_2$ by hydriodic acid; the residues from the preparation of dimethyldiacetylpyrone contain trimethylpyrone, $C_8H_{10}O_2$, and an orcinol derivative, $C_9H_{12}O_2$.—Dehydracetic acid, by J. N. Collie. The author has succeeded in preparing dehydracetic acid from triacetic lactone.—The decomposition of hydroxyamidosulphates by copper sulphate, by E. Divers and T.

Haga.—The degradation of glycollic aldehyde, by H. J. H. Fenton.—Notes on the chemistry of chlorophyll, by L. Marchlewski and C. A. Schunck.—A new series of pentamethylene derivatives, I., by W. H. Perkin, jun., J. F. Thorpe and C. Walker. Ethoxycaronic acid,  $\mathrm{C(CH_3)_2}<\begin{array}{l}\mathrm{C(OC_2H_5)CO_2H}\\ |\\ \mathrm{CH.CO_2H}\end{array}$, is obtained by treating $\alpha\alpha'$-dibromo-$\beta\beta$-dimethylglutarate with alcoholic potash, and yields *asym*-dimethylsuccinic anhydride,  $\begin{array}{l}\mathrm{CMe_2.CO}\\ |\\ \mathrm{CH_2—CO}\end{array}>\mathrm{O}$, with sulphuric acid. Ethyl dibromodimethylglutarate and sodiomalonic ether condense, yielding the sodio-derivative,  $\mathrm{CMe_2}<\begin{array}{ll}\mathrm{C(CO_2Et).} & \mathrm{CNa.CO_2Et}\\ | & |\\ \mathrm{C(CO_2Et).} & \mathrm{CO}\end{array}$; numerous derivatives of this substance are described.—Experiments on the synthesis of camphoric acid. III. The action of sodium and methyl iodide on ethyl dimethylbutanetricarboxylate, by W. H. Perkin, jun., and J. F. Thorpe. Ethyl dimethylbutanetricarboxylate is converted by sodium and methyl iodide into a substance which possibly has the constitution

$$\mathrm{CMe_2}<\begin{array}{ll}\mathrm{CMe(CO_2Et)} & \mathrm{CO}\\ & |\\ \mathrm{CH_2(CO_2Et).} & \mathrm{CH_2}\end{array}$$

which should be easily converted into a substance having the constitution assigned by Bredt to camphoric acid; the ester is converted on reduction into an isomeride of camphanic acid.—The oxyphenoxy- and phenylenoxy-acetic acids, by W. Carter and W. T. Lawrence.—The condensation of ethyl $\alpha$-bromoisobutyrate with ethyl malonates and ethyl cyanacetates; $\alpha$-methyl $\alpha'$-isobutylglutaric acid, by W. T. Lawrence. The author shows that the following general equations hold:—(1) $\mathrm{CNaRX.CO_2Et + CBrMe_2.CO_2Et = CRX(CO_2Et).CMe_2.CO_2Et + NaBr}$, when the sodio-derivative is solid, and (2) $\mathrm{CNaRX.CO_2Et + CBrMe_2.CO_2Et = CRX(CO_2Et).CH_2.CHMe.CO_2Et + NaBr}$, when the sodio-compound is dissolved; $\mathrm{R = H}$ or an alkyl group and $\mathrm{X = .CN}$ or $\mathrm{.CO_2Et}$.—Methylisoamylsuccinic acid, II., by W. T. Lawrence.—The estimation of furfural, by W. Cormack. Furfural may be estimated by oxidising it to pyromucic acid by standard ammoniacal silver oxide solution, filtering off the reduced silver and titrating the silver left in solution.—The constitution of hydrogen cyanide, by J. Wade.—Inhibiting effect of etherification on substitution in phenols, by H. E. Armstrong and E. W. Lewis. The substitution of benzoyl, phenylsulphonyl, benzylsulphonyl, the radicle $\mathrm{C_{10}H_{15}O.SO_2}$, of Reychler's camphorsulphonic acid, or picryl for phenolic hydrogen in phenolparasulphonic acid renders the substance inert towards bromine.—Bromination of oxyazo-compounds, by H. E Armstrong and P. C. C. Isherwood.—Metasulphonation of aniline, by H. E. Armstrong and W. Berry.—Phenylacetylchloramine and analogous compounds, by H. E. Armstrong.—Benzylanilinesulphonic acids, by I. Smedley.—Benzeneorthodisulphonic acid, by H. E. Armstrong and S. S. Napper.—An isomeride of furfurine, by J. P. Millington and H. Hibbert.—The mono- and di-acetyl and phenacetyl diethyl tartrates, by J. McCrae and T. S. Patterson.

July 5.—Prof. Thorpe, president, in the chair.—The Nilson Memorial Lecture was delivered by Prof. Otto Pettersson, of Stockholm.

**Entomological Society**, June 6.—Mr. G. H. Verrall, President, in the chair.—Mr. Hedworth Foulkes, B.Sc., and the Rev. H. C. Lang, M.D., were elected Fellows of the Society.—Mr. G. H. Verrall exhibited a species of the genus *Ceratitis*, MacLeay, apparently identical with Bigot's *C. frenicillatus* from the Gold Coast (West Africa), and a very handsome Trypetid reared from the fruit of *Mimusops caffra* by Mr. Claud Fuller at Durban, Natal.—Mr. C. O. Waterhouse exhibited specimens of a Hemipteron, *Aspongopus nepalensis*. They are much sought after by the natives, who use them for food pounded up and mixed with rice.—Mr. Merrifield exhibited a number of pupæ of *Aporia crataegi*, and called attention to the want of correspondence between the markings on the pupal and those on the imaginal wing. As might be expected of an insect whose larva pupates by preference on stems screened by foliage, its colour is not very greatly affected by its surroundings; on comparing some which had had yellow or orange surroundings with others which had had dark ones, it was shown that the former tended to yellow ground colour, and the latter to grey, having also an increase of the dark spots with which the thorax and abdomen are thickly strewn. He also exhibited some enlarged coloured photographs of the green and dark pupal forms of *Papilio machaon*, obtained by causing the larvæ to pupate on green, yellow or orange surfaces, and on dark ones respectively.—Sir G. F. Hampson exhibited specimens of *Oligostigma araealis*, from Ceylon, where his correspondent, Mr. J. Pole, had met with a swarm on an island in a river which he estimated at 20,000; when disturbed the buzz made by their wings was quite audible, and after three waves of the net 236 specimens were bottled from round its edges, the net still appearing quite full; as, in the some thirty specimens sent, the sexes were in almost even proportions, this was not a case of male assemblage. He also exhibited cleared wings, showing the neuration of *Diacrisia russula*, *Tyria jacobaeae*, *Callimorpha hera* and *C. dominula*, and contended that the genus *Callimorpha* should therefore be removed from the *Arctiadae* and placed in the *Hypsidae* where it is closely allied to *Nyctemara*, *Callarctia* and other genera as the fully developed proboscis, the non-pectinate antennæ, the smoother sealing, the more diurnal habit, and the larvæ being scantily clothed with hair all bore out the correctness of this association.—Dr. Chapman exhibited a portion of a stem of *Ferula communis* from Ile St. Marguerite, near Cannes, showing burrows and pupa cases of *Lozopera francillonana*. A number of vacant holes were also visible, being the exit of an ichneumon, which affects a large majority of the Tortrix, believed to be *Chelonus inanitus*, Nees.—Mr. F. Enock exhibited living specimens of male and female *Ranatra linearis*, Linn., from Epping, together with the peculiar forked eggs, which he had observed laid by the *Ranatra*, as it rested upon the upper surface of the leaf grasping the edges with its claws. The short anterior legs are held well up close together, in a line with the body, the head raised about an inch from the leaf, while the tip of the abdomen and ovipositor is pressed against the leaf—a downward and forward movement being given. The ovipositor is thus forced through the leaf, then partially withdrawn and the egg extruded and forced into the hole as far as the forked filaments, which prevent it from going right through the leaf.—Mr. H. K. Donisthorpe exhibited cases of *Clythra quadripunctata*, specimens of *Lomechusa strumosa*, with its host *Formica sanguinea*, sent by Father Wasmann from Holland, the insects mounted in the position assumed by the guest and host when the former is being fed by the latter. He also showed *Cossyphodes bewickii*, Woll., a beetle from Cape Colony, with the ants with which it is found—*Pheidola megacephala*, var. *punctulata*, Mayr.—Mr. C. J. Barrett exhibited two females of *Spilosoma mendica* reared by Mr. J. E. Robson, of Hartlepool, tinged with purplish-pink, and ordinary specimens of the same for contrast.—A paper was communicated on life-histories of the Hepialid group of Lepidoptera by Mr. Ambrose Quail, and a note on the habits and structure of *Acanthopsyche opacella*, H. Sch., by Dr. T. A. Chapman.

**Zoological Society**, June 19.—Prof. G. B. Howes, F.R.S., Vice-President, in the chair.—Dr. Walter Kidd read a paper on the significance of the hair-slope in certain mammals, in which reference was made to previous investigations into the hair-slope on the extensor surface of the human forearm, and its bearing upon Weissmann's doctrine of the non-inheritance of acquired characters. Details were given of further observations as to the hair-slope on the nasal and frontal regions of certain mammals. The ordinary type and the exceptional type of slope were described, and lists of animals conforming to the two types were given. These results were held to be opposed to the doctrines of Weissmann, and to be attributable to the habits of the animals in question.—Mr. F. E. Beddard, F.R.S., read a paper on the anatomy of *Bassaricyon alleni*, based on an examination of a specimen of this mammal which had recently died in the Society's gardens. The result arrived at was that this genus was clearly referable to the family Procyonidæ, as had been usually supposed, and allied, especially in external form, to *Cercoleptes*, but distinguished by well-marked characters.—Mr. W. F. Lanchester read the first part of a paper on a collection of crustaceans made at Singapore and Malacca by himself and Mr. F. P. Bedford. It contained a list of the Brachyura comprised in the collection, some notes on the nature of the collecting area, and on the habits of certain of the species, together with descriptions of twelve new forms.—A communication was read from Dr. Einar Lönnberg, of Upsala, on the structure and anatomy of the musk-ox (*Ovibos moschatus*). It contained an account of the development of the horns, descriptions of the hoofs and skull, and a comparison between the skull of the musk-ox and that of the Takin (*Budorcas*).—A communication was read from Mr. A. L. Butler, containing the description of a supposed new species of mountain-antelope from the Malay Peninsula, for which the name *Nemorhoedus swettenhami* was proposed.—The Society then adjourned till November next.

**Mathematical Society**, June 14.—Lord Kelvin, G.C.V.O., President, in the chair.—Three foreign members being present, the chairman requested them to make communications to the Society. This they did. Prof. Klein spoke on the continuation of the edition of Gauss's collected works; Prof. Darboux, "Sur différents problèmes relatifs aux transformations de l'espace et aux déformations finis de la matière et sur leurs rapports avec la théorie des systèmes triples orthogonaux"; and Prof. Poincaré, "Sur quelques théorèmes relatifs à l'analysis situs et sur les propriétés des polyèdres dans l'espace à plus de trois dimensions."—Votes of thanks were passed to them by acclamation.—Prof. Stringham also made a few remarks on a proof by non-Euclidian geometry of the form and directrix property of a plane section of a cone.—Prof. Elliott, F.R.S., communicated some notes on the concomitants of binary quantics.—Lord Kelvin read the titles of the following papers which had been received: Some multiform solutions of the partial differential equations of physical mathematics and their applications, Pt. ii., by H. S. Carslaw; Some quadrature formulæ, by W. F. Sheppard; Extensions of the Riemann-Roch theorem in plane geometry, by Dr. Macaulay; On the invariants of a certain differential expression connected with the theory of geodesics, by J. E. Campbell; On the transitive groups of degree $n$ and class $n-1$, by Prof. Burnside, F.R.S.; The invariant syzygies of lowest order for any number of quartics, by A. Young; Canonical reduction of bilinear forms, Pt. ii., by T. J. Bromwich; The energy function of a continuous medium, by H. M. Macdonald; Note on the representation of a circle by a linear equation, by J. Griffiths.

**Geological Society**, June 20.—J. J. H. Teall, F.R.S., President, in the chair.—On the skeleton of a Theriodont reptile from the Baviaans River (Cape Colony), by Prof. H. G. Seeley, F.R.S. The fossil described in this paper was discovered by Mr. W. Pringle at Ealdon, in the bed of the Baviaans River, a tributary of the Great Fish River. It is now preserved in the Albany Museum. The slab containing it is of hard siliceous sandstone, and is 31 inches long by 10 inches wide. It is split so as to expose a portion of the skull, the vertebral column and ribs as far as the pelvis, the scapula, part of the humerus, the femur, and parts of the tibia and fibula. The tail and left hind-limb, and apparently part of the right fore-limb, are lost, owing to the jointed condition of the rock. The bones have decomposed, and are represented by natural moulds from which a beautiful cast was obtained by means of a jelly mould in the Geological Department of the Natural History Museum, before the specimen was returned to Grahamstown. The remains indicate an animal about 2 feet long, exclusive of the tail, and standing probably about 8 inches high; it was not more than 6 inches wide in the fore part of the body. The animal was of great mobility, capable of easily bending the body, and, by straightening the limbs, of occasionally raising its height to 10 inches or more. It is a new type of Theriodont reptile, contributing important facts to the osteology of the group, and especially in regard to the natural association of the bones. It is possibly to be included in the Cynodontia, from which it differs in characters of the ilium, scapula, and skull.—Fossils in the Oxford University Museum (IV.): notes on some undescribed trilobites, by H. H. Thomas. Two new species of *Dalmania* from the Wenlock Shales and one of *Olenus* from the Shineton Shales of Shropshire are described in this paper. The specimens on which the first species of *Dalmania* is founded were collected by the late Dr. Grindrod at Malvern Tunnel. The species has a strong resemblance to certain varieties of *D. caudatus*, especially those more nearly approaching *D. longicaudatus*; its nearest ally seems to be *D. nexilis*. Among its characters are spines round the head, the height of the head-shield, and the distance between the eyes. The type-specimen of the second species came from the Wenlock Shale of Builth. The Shineton specimen was presented to the Oxford Museum by the Right Rev. Bishop Mitchinson.—On radiolaria from the Upper Chalk at Coulsdon (Surrey), by W. Murton Holmes. The radiolaria described in this paper were contained in the cavities of two small flints which were thrown out of the new cutting between Coulsdon Station and the new Merstham Tunnel on the L. B. & S. C. Railway. They were probably derived from the zone of *Holaster planus*. After treatment with hydrochloric acid, the material yielded silicified casts of foraminifera as well as radiolaria. The surface of the radiolaria is so much altered by corrosion that specific identification is in most cases impossible. Twenty genera have been recognised, and the organisms appear to belong to forty-one species of these genera. A list of the radiolaria is given, accompanied by a short description of each form, and four new species are described. The Discoidea appear to have the predominance, and the species of *Dictyomitra* come next in numerical order.—The Society then adjourned until Wednesday, November 7.

**Linnean Society**, June 21.—Dr. A. Günther, F.R.S., Vice-President, in the chair.—Prof. M. Hartog exhibited and made remarks on flowers of new *Abutilon*-seedlings, recently raised by him, and pointed out the extreme variability shown in the form of many of the leaves.—Dr. O. Stapf exhibited fruits of various forms of *Trapa* from Europe, China and India, and discussed the differentiation of the genus into species.—Mr. Clement Reid, F.R.S., exhibited a series of plum-stones recently found in a drain of the Roman baths, and in a rubbish pit, at Silchester. The species identified were Cherry (*Prunus avium*), Damson (*P. domestica*), Bullace (*P. insititia*), Sloe (*P. spinosa*), and Portuguese Laurel (*P. Lauro-cerasus*). Besides these, there was a large variety of Plum, and a very small Sloe, the species of which had not as yet been precisely determined.—On behalf of Dr. O. St. Brody, Mr. B. Daydon Jackson exhibited a small series of British orchids dried by a new process, by which the flexibility of the plant and the natural colours were in a great measure retained.—Mr. R. Morton Middleton exhibited several rush baskets, plaited ropes and dredgers made from *Rostkovia grandiflora*, Hook. f.; and a crab-catcher and limpet-detacher made from *Berberis ilicifolia*, Forster, all used by the Yahgans south of Beagle Channel, Tierra del Fuego.—Mr. F. Enock exhibited and made remarks upon some living specimens of *Ranatra linearis*, Linn., together with their curious eggs.—A paper by Miss Georgina Sweet, Melbourne, was read, "On the Structure of the Spermiducal Glands and associated parts in Australian Earthworms."—Dr. Charles Chilton read a paper on the subterranean Amphipoda of the British Islands, reviewing the known species of the genus *Gammarus*, and giving some account of the "Well-Shrimp" and its distribution in England so far as he had been able to determine it from specimens collected.—Dr. A. B. Rendle, referring to his recently published "Revision of the genus *Najas*" (*Trans.* Linn. Soc. 2nd Ser., Bot. vol. v. Part 12), read a supplementary paper on the same subject, in which he gave additional information gained from a recent examination of specimens in eleven Continental herbaria, particularly those at Paris, Geneva, Vienna and Berlin.—The Society then adjourned until Thursday, November 1.

### DUBLIN.

**Royal Dublin Society**, May 16.—The Earl of Rosse, F.R.S., in the chair.—Mr. R. J. Moss read a paper on the adhesive and other physical properties of copper preparations used in potato spraying.—Dr. W. E. Adeney read a paper, entitled "Studies in the analysis of fresh and salt waters."

June 20.—Sir Howard Grubb, F.R.S., in the chair.—Mr. J. A. Cunningham read a paper, entitled "A contribution to the theory of the order of crystallisation of the minerals in igneous rocks." The author discussed the theory recently published by Dr. J. Joly, F.R.S. (*Sci. Proc. Roy. Dubl. Soc.* vol. ix. part 3, No. 20, p. 298), and then gave additional facts in support of Bunsen's theory, that the order of melting points of the minerals may be inverted by pressure. Mr. Cunningham showed a rough method of arriving at the relative latent heats of the minerals by means of their fusibilities; and proceeded to show how the latent heats might be determined by simple chemical measurements. As an example, in the case of quartz, the specific heats of quartz and amorphous silica are already known, and by measuring the difference of the heats of solution of the two substances in HF, the disengagement of heat in passing from the one form of $SiO_2$ to the other at any temperature is known. Thus, assuming 1425° C. as the melting point of quartz, the number 135·3 was arrived at as a safe minimum for the latent heat of quartz.—Prof. J. Joly, F.R.S., communicated a paper on the order of crystallisation of silicates in igneous rocks. Referring to a previous communication, the author has extended the observations of the viscous yield of quartz fibres to a temperature of 735° C. Dealing with finely powdered rock-crystal, it is found that this when wrapped in strong platinum foil and exposed for twenty-four hours in a Bunsen flame, shows unmistakable evidence of softening. The powder is loosely caked, and although the great mass is apparently optically unaltered, the particles which have been pressed against the platinum have adhered and melted into blebs, which cannot be removed by friction. Their examination is effected by a vertical illuminator and high power. Finely powdered quartz placed in the meldometer and exposed for four hours to a temperature between 1085° C. and 1070° shows similar evidence of fusion. Finely powdered olivine, augite, hornblende and quartz exposed in the meldometer for two and a half hours to a temperature between 1105° C. and 1080° reveal, on subsequent examination, that the evidence of fusion was conspicuously more apparent in the case of quartz. The experiments were repeated in an atmosphere of $CO_2$, as coloration changes thought to be due to oxidation appear on heating in the case of hornblende and olivine. In $CO_2$ these changes still appear in less degree. Results otherwise the same as before. The author urges that these results support his view that the softening temperature of the silicates will not be found discordant with the observed normal order of solidification in igneous rocks, but will be found to harmonise with Rosenbusch's law, the depression of the softening point in the scale of temperature being influenced by the amount of silica in combination. On the legitimacy of recent attempts to apply the thermodynamic expression connecting $dp/dt$ with change of volume in reversible systems, the author points out that calculations based on the change of volume of a crystallised silicate to its glass must give erroneous results, and possibly widely erroneous results, seeing that the glass has never existed in the magma at any time, but the crystal was built up from the molecules diffused in the magma. The withdrawal of the molecules from solution may probably have given rise to a volume-change which cannot be ignored.—Mr. S. R. Bennett read a paper containing the results of actinometric observations of the solar eclipse. By exposing an actinometer at intervals of a few minutes throughout the afternoon of the solar eclipse of May 28, it was found that the actinic power of the sun's rays declined rapidly from 2h. 13m. to 3h. 40m. and then increased more rapidly till 4h. 27m. After this there was a regular decrease due to the approach of evening. The exposure at 2h. 13m. was 50s., at 3h. 40m. it was 101s., and 86s. at 4h. 27m. Curves were plotted to represent these results as well as the corresponding ones deducible from theoretical considerations. The curves representing the eclipse effect as found from observation and from theory (on the assumption that the amount of light received from the sun is proportional to the area of his disc exposed) did not agree. That found from observation indicated a greater amount of light received, in the ratio of 2·3 to 1·6 at 3h. 22m., the moment of greatest phase. No satisfactory explanation of this incongruity was given.—Mr. Charles Martin read a paper on heat-radiation observations made at Dunsink Observatory during the eclipse of May 28.

### EDINBURGH.

**Royal Society**, June 18.—Dr. Burgess in the chair.—Prof. Copeland and Mr. Thomas Heath gave descriptions of the preliminary work, the installation of instruments, and the general character of the observations made by them at the recent eclipse. Mr. Heath's communication gave a particular account of the various operations undertaken in connection with the 6-inch Cooke triple object-glass. This object-glass was constructed so as to bring to one focus both the visual and photographic rays. Tested by the most severe tests the instrument was perfectly achromatic. Four photographs of the corona were taken during totality on plates 8½ by 6½ inches. Prof. Copeland manipulated the 40-foot telescope which has already done duty on previous occasions. Mr. Frankland Adams had charge of cameras for taking long exposure photographs, and in the working of these had the valuable assistance of officers of H.M.S. *Theseus*. The navigating officer supplied them with time signals; and by means of beautiful maps, for which they were indebted to the courtesy of the director of the Madrid Observatory, they were able to determine with great ease and accuracy the latitude and longitude of their station near Santa Pola. The Spanish authorities did everything possible to facilitate their operations; and the members of the expedition experienced nothing but kindness at the hands of the people of the town. Photographs began to be taken 16 seconds before totality, and were continued for 60 seconds after totality. The first contact was observed by Prof. Copeland 10·2 seconds sooner than the time expected, there being a projecting mountain ridge on the limb of the moon which first moved across the sun's edge. The shadow bands which occur just before and just after totality were observed by some of the men of the *Theseus* on a vertical wall which had previously been coated with plaster of Paris.—Dr. Buchan and Mr. Omond reported to the Society the nature of the publication of the Ben Nevis observations. For the satisfactory development of meteorological science it was necessary to publish the continuous daily records, and not merely monthly or weekly means. This was now being done with the Ben Nevis observations, both high-level and low-level; and when the work was completed the meteorologist would be in a position to discuss many problems of the greatest interest and importance. It would require three volumes of the Society's *Transactions* to complete the publication of the observations on the scale that had been determined upon. To meet the expense of publication, the Royal Society of London had voted 500*l.*, and an equal grant had been voted by the Royal Society of Edinburgh.

July 2.—Sir Arthur Mitchell, Vice-President, in the chair.—In a paper on the craniology of the people of India, Part ii, Sir William Turner, F.R.S., described the skulls of the aboriginal hill tribes from the Central Provinces, Chiita, Nagpur, and Orissa. Most of the specimens were in the Indian Museum, Calcutta, but others were in the Anatomical Museum of the University of Edinburgh. They belonged to the so-called Kolarian and Dravidian groups of people. From a comparison of skulls the conclusion was drawn which supported the view advocated by Mr. H. H. Risley from the examination of living persons, that these groups did not differ from each other in physical characters, and that they formed a Dravidian type. A comparison was also made of the Dravidian type of skull with the Australians and the Negritos of the Andaman Islands. Skulls of the Uriya speaking people of Orissa were also described, and the presence of dolichocephalic and brachycephalic types, with skulls of intermediate or mesaticephalic proportions, was shown to occur amongst them.—Sir John Murray and Mr. F. P. Pullar communicated the second part of their bathymetrical survey of the fresh-water lochs of Scotland, in which they dealt with Lochs Chon, Ard, Monteith, and Leven of the Forth drainage area, and with Lochs Ericht and Garry in the Tay basin. These lochs differ greatly in elevation, the extremes being: Monteith, 55 feet above the sea; Ericht, 1152 feet above the sea-level. Their areas vary from 277 acres (Chon) to 4690 acres (Ericht). In this most elevated of the larger lochs of Scotland there are two depressions in which the depth exceeds 300 feet, the maximum depth recorded being 512 feet. The deposits in the deeper parts of all the six lochs consist of a dark brown mud containing much organic matter, but in some there is a second layer, three to six inches beneath the upper layer, of a light brown colour and greater consistency, containing less organic matter. Numerous examples were given of the effect of the wind in driving the warmer surface waters towards the leeward end or side of a loch and in drawing up the colder and deeper layers towards the windward end or side. The shallow lochs were warmer in spring and summer than the deeper lochs, and contained more pelagic life. In these discussions it was important to bear in mind the fundamental difference between temperature and amount of heat. It was calculated that the larger lochs with their much smaller change in temperature really stored up more heat than the smaller lochs with their greater change in temperature.—A note by Dr. R. Sydney Marsden was read, drawing attention to a paper he had read in 1880 (see *Proc.* R.S.E., 1881), which contained an account of his method for the artificial preparation of diamonds. M. Henri Moissan, of Paris, described in 1893 a method for the preparation of adamantine carbon which differed from Dr. Marsden's method in details which did not seem to be essential. The note was a claim for priority in a matter in which the later experimenter was now getting all the credit in the eyes of the scientific world.

### PARIS.

**Academy of Sciences**, July 2.—M. Maurice Lévy in the chair.—Communication from M. Darboux concerning the International Association of Academies (p. 249).—Permanent but unequal heating by radiation of a wall of indefinite thickness reduced to the case of an analogous heating by contact, by M. J. Boussinesq.—The combustible gases of the atmosphere; the air of woods and of mountains, by M. Armand Gautier. Following up the experiments, previously described, made with the air of Paris, air was examined in the middle of a pine wood, and on the summit of a mountain away from all vegetation. The ratios of carbon to hydrogen found in the three cases were 3·5 for Paris, 2·2 in the air of woods, and 0·33 in the mountain air, the quantities of hydrocarbons per 100 litres of air expressed as methane being 22·6 c.c., 11·3 c.c., and 2·2 c.c. respectively. It was also found that air taken at a high altitude, collected in a place denuded as far as possible of animals, plants and humus, is nearly entirely free from hydrocarbons, but still contains about 2/10,000,000ths of its volume of free hydrogen.—Synthesis of *αα*-dimethyl-*γ*-cyanotricarballylic ester and of the corresponding acid, by MM. A. Haller and G. Blanc. Cyanosuccinic ethyl ester is heated with sodium ethylate and *α*-bromoisobutyric acid, and the resulting ester separated in the usual way.—M. Zambaco was elected a correspondent for the Section of Medicine and Surgery.—Occultation of Saturn of June 13 observed with the Brunner equatorial at the Observatory of Lyons, by M. J. Guillaume.—On a prerogative of the Gregorian Calendar, by M. Joseph Lais.—On the method of Neumann and the problem of Dirichlet, by M. A. Korn.—On the motion of a wire in space, by M. G. Floquet.—On the propagation of condensed waves in hot gases, by M. H. Le Chatelier.—On the decomposition of harmonics by the ear, by M. F. Larroque.—On the thermo-electricity of some alloys, by M. Emile Steinmann. Nickel steel containing 28 per cent. of nickel gave an electromotive force against lead of 385 microvolts between 20° and 260° C.—On the true atomic weights of ten elements deduced from recent works, by M. G. Hinrichs. By applying the method previously described by the author to some recent determinations of atomic weights, the latter are made to appear as whole numbers exactly.—Attempt at a general theory of acidity, by M. de Forcrand. The theory put forward allows of the prediction of the acidity of a compound containing hydrogen replaceable by a metal when the formula of constitution is known; and also of the heat of fusion when this cannot be determined directly.—Addition of hydrogen to acetylene and ethylene in presence of finely divided platinum, by MM. Paul Sabatier and J. B. Senderens. A mixture of hydrogen and acetylene, the former being in excess, when passed over platinum black reacts vigorously, ethane together with a little ethylene being produced, the secondary products noticeable with nickel being practically absent. With acetylene in excess, ethylene is the chief product, although ethane is still produced in notable quantities. Working at 180° instead of at ordinary temperatures the reaction becomes more vigorous, but the quantity of secondary condensation products increases.—On the methoxy-hydratropic acid obtained by the oxidation of anethol. Identity of phloretic acid and of hydropara-coumaric acid, by M. J. Bougault.—Method for preparing synthetically higher homologues of acetolacetic ester and acetylacetone, by M. L. Bouveault. By the interaction of acetoacetic ether and the fatty acid chlorides, the *β*-ketonic ethers and *β*-diketones are easily obtained.—On the mode of formation of the compounds [$C_2H_2.(Cu_2Cl_2).KCl$ and $C_2H_2[(Cu_2Cl_2)_2KCl.]$, by M. Chavastelon.—On the metallic compounds of diazoamido-benzene, by M. Louis Meunier.—Action of nitric acid upon trichlor-guaiacol, by M. H. Cousin. The action of nitric acid upon the trichlor-derivative is quite different from that of the tetrachlor- and tetrabromo-derivatives as instead of the orthoquinones produced in the latter case, a complicated condensation product is produced.—On the aloins, by M. E. Léger.—Solubility of cupric chloride in organic solvents, by M. Œschner de Coninck.—On the composition of the albumin of the seed of *Gleditschia triacanthos*, by M. Maurice Goret. The reserve hydrocarbon in this case is a mannogalactane; hydrolysis yielding only a mixture of mannose and galactose.—Hermaphroditism and parthenogenesis in the Echinoderms, by M. C. Figuer.—Study of the digestive apparatus of *Brachytrupes achatinus*, by M. L. Bordas.—Prehnite considered as a constitutive element of metamorphic limestones, by M. A. Lacroix.—On the combinations of the nucleins with metallic compounds, alkaloids and toxins, by M. H. Stassano.—The power of selective coloration by methylene blue, possessed by living spore-bearing filaments of *Spirobacillus gigas*, by M. A. Certes.—A preventive remedy against the mannite disease of vines, by M. P. Carles.

### CAPE TOWN.

**South African Philosophical Society**, June 6.—L. Péringuey, President, in the chair.—Mr. W. L. Sclater exhibited a series of photographs of birds and their nests taken by Mr. R. H. Ivy, in the neighbourhood of Grahamstown.—Dr. J. D. F. Gilchrist exhibited:—(1) A Gadoid fish, belonging to the genus *Haloporphyrus* and probably a new species, found by the Government steamer in trawling about 40 miles off Cape Town, in over 100 fathoms. (2) Four fishes showing luminous organs, viz.: a *Monocentris* from shallow water, Mossel Bay; an *Argyropelecus*, a *Paraliparis* and a *Scopelus* from over 100 fathoms off the Cape Peninsula, probably all new species. (3) A number of new Alcyonarians which have been procured by the Government steamer and described by Prof. Hickson, F.R.S. These included the new genus, *Acrophytum claviger*, and three new species—*Heteroxeina capensis*, *Sarcophytum trochiforme*, *Gorgonia capensis*. (4) Specimens of *Veritillum* illustrating the difference in size of the fauna of the east and west coasts of Africa, the eastern forms being larger than those from the west coast. (5) A specimen of *Agriopus torvus*. (6) A new species of Anchovy from East London, this being the second species of the genus *Engraulis* discovered in South African waters.—Dr. F. Purcell exhibited specimens of all the known South African species of Peripatus, including, in addition to the three previously described forms, four others recently described by himself in the annals of the museum, making seven in all. Dr. Purcell in his remarks on the genus maintained that the supposed great antiquity of Peripatus was very doubtful, depending as it did on the supposition that the tracheæ of the tracheate Arthropods could only have originated once, for it is now known that true tracheæ have originated independently in at least three different ways, for instance, in two ways in spiders and in a third way in insects. It would be reasonable to suppose, therefore, that Peripatus may also have acquired its tracheæ independently of those of the insects.

THURSDAY, JULY 19, 1900.

## THE RELATIONS BETWEEN ETHER AND MATTER.

*Æther and Matter.* By Joseph Larmor. Pp. xxviii + 365. (Cambridge University Press, 1900.)

THIS work is essentially the same as an essay to which an Adams Prize was awarded by the University of Cambridge. The subject for which the prize was offered was Aberration, and as this phenomenon, together with the Doppler effect on the frequency of light vibrations are the only ones known due to the motion of matter through the ether (the spelling æther is disagreeably cumbrous), it naturally led to a discussion of the connection between ether and matter, and the effect of their relative motion on the phenomena of electro-magnetism.

There is a good deal of similarity between the development of this work and that of Maxwell's treatise. If one reads Maxwell's papers, it is pretty evident that he began with a somewhat definite hypothesis as to the nature of the strains in the ether to which he attributed electromagnetic phenomena; but in his treatise on electricity and magnetism there is hardly a trace of all this except in the reference to molecular vortices by which he justifies his equations for wave-propagation in magnetised media. In a similar way, Mr. Larmor has published papers in which the relations between ether and matter are developed in connection with a suggestion as to the nature of an electron which is only hinted at in the body of the present work, and is relegated to an appendix with some deprecatory remarks as to its being merely an analogy to show that the properties of an electron are not impossible. The hypothetical structure attributed to an electron requires the medium to possess a very remarkable property which we do not find in matter, namely, an elastic reaction against absolute rotation of its elements; and although Mr. Larmor shows that gyrostats connected with these elements might confer such a property on them, he does not go so far as to develop any very definite structure for the medium, contenting himself with having shown that such properties as he assumes are not necessarily anti-dynamical. No structure for the medium that depends on gyrostats supported by a rigid framework can possibly be more than a rough working hypothesis, being, in fact, very little better than the brass wheel and india-rubber band, or tubes full of liquid with circulating pumps, that have been suggested as models to show that Maxwell's equations do not necessarily postulate impossible or adynamical properties for the ether.

But just as Maxwell's treatise is really independent of the dynamical analogies from which it grew, so Mr. Larmor's work is really independent of his suggested working analogy as to the structure of an electron. The whole work is based upon the hypothesis that electricity is atomic in its nature, there being only two kinds of atoms, positive and negative electrons. These electrons are, he supposes, essentially centres of strain in the ether, and move from place to place in much the same way as a drop of water might move through ice, melting in front and freezing up behind. Mr. Larmor leaves it for future investigation to determine whether there is any core, like that of a vortex ring, that accompanies this complex strain wave as it moves through the ether. As to the nature of matter, the only suggestion is that it consists of clusters of electrons in orbital motion round one another; but as the dynamics of such a system has never been worked out, it is impossible either to assert or deny the possibility of a permanent existence of such clusters. If this be the structure of matter, it certainly makes it probable that the transmutation of the elements is a possible development of chemistry, while a structure such as that of knotted vortices would make it improbable that we would ever be able to untie them and thus transmute one atom into another. There is the alternative possibility that we may find means of transmuting elements within any one of their related groups, but that we may find ourselves unable ever to transmute one group into another. Of course, if we ever found out some means of manufacturing electrons and matter we could probably transmute one kind of matter into another, though this latter might be possible according to Mr. Larmor's hypothesis, while the manufacture of either electrons or matter would be impossible.

All theories that explain electric currents by the motion of electrons are really based upon Rowland's classical experiment, that a moving electric charge produces the same magnetic effects as an electric current, and its converse that the electric force due to changing magnetic induction produces the same effect in moving an electric charge that the electric force due to another electric charge would produce, *i.e.* that electric force due to these two causes is the same. Our whole treatment of electro-magnetism is practically based upon these same assumptions, but it is remarkable that so few attempts have been made to repeat this fundamental experiment of Rowland's, and no successful attempt seems to have been made to directly verify its converse. In a recent number of the *Comptes rendus* there is an account of a most interesting attempt to measure the electric current that one would expect to be produced in a surrounding coil when a convection current such as Rowland studied is being started and stopped. M. Cremieu has carried out an experiment on this with great care, and in a form in which one would certainly expect that the changing magnetic induction due to the magnetic force Rowland observed should produce an induced current in a coil of wire. He observed no such effect, and concludes that there is no magnetic force such as Rowland observed due to a moving electric charge. These moving electric charges are, however, in some respects, so imperfectly known that there may yet be some difference between driving a current by mechanical and electrical forces, and that it is still possible there may be some other explanation than that drawn by M. Cremieu as the result of his interesting and important experiment. Mr. Larmor's investigations in this treatise of the effects of moving matter hardly touch the question raised by M. Cremieu, for his investigation is concerned with steady states, while M. Cremieu's experiment is essentially concerned with variable ones. If he is right and there is really no magnetic force due to a moving electric charge, and if consequently we must look to some other, possibly accidental, cause for Rowland's observation, it will certainly revolutionise the whole modern treatment of electro-magnetism. The question raised by this experiment is, any way, one of the most fundamental ones in the connection between ether and matter, and it is to be hoped that this question will be settled soon in a conclusive way, either by showing that M. Cremieu's conclusion is not justified by his observation that his experiment really confirms a complete theory, or by overthrowing all our existing views, and leaving a free field for the twentieth century to build a new theory of electro-magnetism on a firmer foundation.

In discussing the result of Michelson and Morley's experiments, from which they concluded that the ether is carried along by the earth in its motion, Mr. Larmor shows that such a hypothesis is quite inconsistent with the fact of aberration and with the untenability of Sir George Stokes's suggestion that ether is like a very soft jelly. How such a soft material could be the means by which tramcars are driven by shearing stresses seems an additional difficulty in the way of this suggestion. Mr. Larmor concludes that the stone support on which the mirrors were borne changed in its dimensions, as it was rotated, by an amount proportional to the square of the ratio of its velocity to the velocity of light, and he justifies this by showing that if matter consists of clusters of electrons, just such a change of dimensions would take place as the experiment shows to take place. There is some difficulty in the hypothesis that the inertia of matter, or any large part of it, is like that of electrons and due to the motion of the neighbouring ether, because this involves the supposition that the inertia would change with the distance between the component electrons. That there may be some very minute effect of this kind is quite possible, though as yet undiscovered, but that any large effect of the kind exists seems extremely improbable. Possibly a careful study of the accuracy of Kepler's laws as applied to the solar system might show some discrepancy depending on a difference between the average distance of the electrons in such different materials as probably constitute Neptune and Mercury.

A previous question to all our explanations of phenomena by analytical dynamics is raised by Mr. Larmor in Appendix B, "On the Scope of Mechanical Explanation: and on the Idea of Force." He has utilised the principle of least action throughout his work, and this appendix is a justification of his doing so, and besides raises questions as to the applicability of dynamical explanation to the growth and decay of vital organisms. Hertz objected to the adequacy of the principle of least action as a complete solution of all possible dynamical systems, because it is not generally applicable when rolling takes place, and we cannot be sure that rolling may not be one of the fundamental facts of the dynamics of the ether. Mr. Larmor dismisses this objection on the doubtful ground that "rolling is foreign to molecular dynamics." Hertz had also objected to the principle of least action for the semi-metaphysical reason that it makes the present state of the system depend on the future as well as on the past. As Mr. Larmor himself uses in his work the vector potential which makes the state at each place depend on what is simultaneously occurring at all parts of the universe, he naturally finds no objection to the principle of least action, because it makes the present depend on all future time. Neither of these methods is unobjectionable; each is an analytical juggle, which has to be most carefully guarded lest it lead us into mistakes. The way in which the vector potential apparently locates the energy in the current instead of in the magnetic field outside it is a most serious objection to its use, although Mr. Larmor seems to have steered clear of the difficulties raised by this curious complication. In a similar way the principle of least action is open to the objection of Hertz of making the present apparently depend on the future to an extent that does not apply to his own principle of the straightest path. It is a question for consideration in connection with Mr. Larmor's discussion on the applicability of dynamics to vital phenomena whether the possibility of determining our actions by considerations as to the future is not connected with the possibility of analytically expressing the dynamics of the present by a formula which involves the future.

It will, from this meagre review, be evident that Mr. Larmor's treatise raises most fundamental and interesting questions, and is one that all who desire to strengthen the foundations of our knowledge of nature should carefully study. GEO. FRAS. FITZGERALD.

## LAND RECLAMATION.

*The Reclamation of Land from Tidal Waters.* By Alexander Beazeley, M.Instit.C.E. Pp. xii + 314. (London: Crosby Lockwood and Son, 1900.)

THE area of this country is gradually diminishing by the continual waste that is going on all round the coast. On the Yorkshire coast it is estimated that two miles have disappeared since the Roman occupation; and more modern records show that towns and villages have disappeared with their houses and churches, and in some cases the whole parish has been washed away. Along the Norfolk coast the only record of several villages is, "washed away by the sea"; and on the Kentish coast, churches and houses have fallen down the cliffs, on which are to be seen the bones formerly deposited in a vanishing churchyard. On the south coast, although the chalk cliffs at the east end of the English Channel are subject to continual falls and slips, more care has been taken to protect them; but along the clay cliffs of Dorsetshire the waste is continuous; here twenty acres slipped down seaward in one night from the cliffs at Axminster. On the west coast, the nets of the fishermen are said to become occasionally entangled with the ruins of houses and buildings buried in the sea some distance from the coast off Blackpool.

As some compensation for all this loss due to the ever-continuous operations of nature, the energy of man has succeeded in reclaiming and recovering a large area of rich cultivatable land in estuaries where rivers have discharged great quantities of detritus picked up along their course. At no time in the history of this country were reclamations carried on to a greater extent than in the time of the Romans, and this is the more remarkable as, compared with the population at that time, land must have been plentiful. It was during this era that the great tract of low land lying on the east of England was reclaimed from the sea by the construction of 50 miles of sea-banks, and the 60,000 acres in the district known as Romney Marsh was protected from the sea by a bank 4 miles long and 20 feet high. From the time of the Romans to the Stuart period very little seems to have been attempted in this way, but at that time there are records of innumerable grants made to "undertakers" and "adventurers" who undertook to reclaim the low lands in the Isle of Axholme, Haxey Chase and the Fens of Lincolnshire and Cambridgeshire, and other parts of the country, in return for a certain proportion of the land reclaimed. Another revival took place during the present century at the time when agriculture was prosperous, and land-owners were tempted, by the high rents then paid, to reclaim from the sea numerous intakes of salt marshes by the construction of sea banks in the estuaries of the Humber, the Wash, the Thames, the Severn and other rivers. Since rents have fallen and land-owners have become impoverished by the low rents, and the heavy charges thrown on estates by the payment of the death duties, little or no inclosing has taken place. Land, however, shows signs of recovering something of its former value. The appearance, therefore, of a book dealing with the reclamation of land from tidal waters may be considered as opportune.

The only standard English book on this subject is that of the late Mr. John Wiggins on the "Practice of Embanking Lands from the Sea," which is now out of print. Instead of publishing a new edition with the extensive alterations of the text that would be required to bring this work up to date, the author of the book now under review was invited by the publishers to undertake the preparation of a new treatise, in which all that was applicable to modern practice in Mr. Wiggins' book has been incorporated.

The author has carried out his task efficiently and well, and his book contains a large amount of information that will be of great service to engineers, and also to landed proprietors and others interested in works of reclamation.

The book makes no pretensions to originality; on the contrary, it may be regarded as an epitome of the information and opinions contained in a vast number of papers contained in the *Minutes of Proceedings* of the Institution of Civil Engineers and the papers of allied societies, and in the works of authors on drainage and Fen history.

A careful perusal of a book of this character, and the principles laid down that should be observed in the reclamation of land, might have saved the expenditure of many thousands of pounds on schemes that never came to maturity or have proved financially disastrous. Of these, as examples, may be quoted the great scheme that was at one time entertained, and still has advocates, for the formation of a new county in the Wash, by the enclosure of the sands; an offshoot of which was the abortive scheme of Sir John Rennie for reclaiming 30,000 acres, the greater part of which was bare sands, which experience has since proved would have been utterly unfit for cultivation; and the Norfolk Estuary Scheme, which received parliamentary sanction in 1846 to reclaim 30,000 acres submerged at high water, and of which up to the present time, after an expenditure of nearly 400,000*l*., there has only been reclaimed 2000 acres of marsh land adjacent to the coast, a great part of which formed the bed of the diverted river. In this case, great benefit has resulted to the drainage of the country by a new direct cut made for the outfall of the river Ouse; but as a land reclamation scheme, it has been a most disastrous failure, owing to the misconception of the promoters as to the action of the sea in forming deposit on the coast, and of the difficulties attending the construction of sea banks.

Mr. Beazeley's book is divided into nine chapters, dealing respectively with: (1) General observations; (2) the site for a bank; (3) the construction of sea banks; (4) the drainage of the land reclaimed; (5) maintenance and repair of sea banks; (6) warping land; (7) cultivation after enclosure; (8) examples of reclamation, value and rents; (9) legal requirements; the text being accompanied by numerous illustrations.

## THE MAMMALIAN BRAIN.

*Handbuch der Anatomie und vergleichenden Anatomie des Centralnervensystems der Säugetiere.* Von Dr. Edw. Flatau und Dr. L. Jacobsohn. I. Makroskopischer Teil, mit 126 Abbildungen im Text, und 22 Abbildungen auf 7 Tafeln. Pp. xvi + 578. (Berlin: Verlag von S. Karger, 1899.)

THE handsome volume before us is a welcome addition to works on the comparative anatomy of the mammalian brain. That the literature of this subject is already vast, may be gathered from the fact that nearly 300 papers are quoted at the end of the volume—this list forming indeed a most useful bibliography. So numerous and scattered are these various works, that only those students who have access to very complete libraries can hope to be able to consult the majority of them, and we have long felt the want of a trustworthy account of the structure of the brains of the various orders of mammalia in a more handy form. This want is to a great extent satisfied by the work of Drs. Flatau and Jacobsohn, which is rather of the nature of an original contribution than of a text-book. For it is no mere compilation; but, on the contrary, almost entirely consists of the description of brains studied by the authors themselves in Prof. Waldeyer's Anatomical Institute in Berlin.

With admirable care the authors describe the structure of the central nervous system of representative examples of all the living orders of mammalia. To give the reader some idea of the thoroughness of their method, one may mention that in the case of the brain of the Chimpanzee, for example, we find paragraphs on the brain weight, the relation of the brain to the skull, the general shape and measurements of the brain, followed by detailed accounts of the convolutions of the cerebral hemispheres, the structure of the corpus callosum, fornix, &c., of the Diencephalon, Mesencephalon, Metencephalon, Myelencephalon, and Medulla spinalis. Naturally the types of all the orders are not treated in quite as much detail as the Chimpanzee. At the end of the chapter on monkeys and apes are elaborate tabular statements of the authors' observations compared with those of previous writers on the subject. Throughout, the text is illustrated by excellent figures, almost all of which are original. The general reader will be especially attracted by the ingenious representations of the brain drawn inside the skull as if seen by transparency, and by the really beautiful series of plates at the end of the volume.

The work is essentially a technical and a practical one. Nevertheless, a final chapter is devoted to a general summary and conclusions. Here Drs. Flatau and Jacobsohn aim, not at bringing forth sensational results, but soberly review such general conclusions as may safely be drawn at present. These, it must be confessed, are somewhat disappointing, not, be it understood, through any fault of the authors, but owing to the inherent difficulties and complications of the subject, and the comparatively few data yet at our disposal.

As to the attempt to homologise the fissures of the cerebral hemispheres with one another in the various orders of mammalia, Drs. Flatau and Jacobsohn freely adopt Gegenbaur's conclusion, that this can only be done to a very limited extent. In most of the orders we generally find some small and lowly organised forms with almost smooth brains; and it must always be borne in mind that the fissures and convolutions may to a great extent have been independently developed in each group.

Of the usefulness of this volume there can be no doubt, and the appearance of the continuation of the work will be awaited with interest by all workers in the subject of brain anatomy.

## OUR BOOK SHELF.

*The Origin of the British Flora.* By Clement Reid, F.R.S., F.L.S., F.G.S. Pp. vii + 191. (London: Dulau and Co., 1899.)

THIS is a useful contribution to the literature of geographical botany; but it is unfortunate that the author has given it the ambitious title of "Origin of the British Flora." Any one entering upon the perusal of the book with the expectation engendered by its title will soon meet with disappointment, but must not be blinded thereby to its real merit, which is great, and consists in the historical records, to which two-thirds of it are devoted. The book is essentially a geologist's account of the palæontological evidence of the distribution of plants in Britain during recent geological periods. Every one will agree with the author in thinking that the historical method is the proper one for determining questions of origin, but that the "problem of the origin of our flora is one which can be solved by this method" is surely a sanguine forecast on his part, even allowing for the fact that the flora of our Tertiary deposits has not been worked out yet with much completeness; his work is emphatic testimony to the fragmentary character of historical evidence in relation to the British flora that has been obtained up to the present time. In his "Table showing the Range in Time of the British Flora," which includes the names of species, remains of which have been found in deposits of pre-Glacial age onwards, there are not three hundred names, and of these not all have as yet been found in deposits within the present area of Britain; and, moreover, the finds do not touch elements of the flora which have always been a crux in explanations of its origin. The first fifty pages of the book deal, in the slight manner of the magazine article rather than in the detail of a scientific treatise, with some of the problems of the origin of the present British flora. The author is on the side of those who attribute a more important influence to air-transport than to land-connection as a factor in the making of our existing flora. The Watson-Forbes hypothesis is, in a few sentences, put on one side, and a short chapter is devoted to an account of the transport-mechanism observable in the species of the flora. In Chapter iv. we have an account of the author's idea of the geographical and climatic changes affecting Britain in the late Tertiary times; the former, the author thinks, "were of no very great importance as bearing on the past history of our flora," although they "must have tended greatly to modify local conditions, and must have sometimes aided, sometimes have hindered, the dispersal of the seeds"; the latter have left their mark on the flora; but at the same time "Britain shows signs of a geographical distribution of plants largely independent of that due to climate; or perhaps we should say not governed by existing climatic conditions." It is not, however, these brief earlier chapters which give value to the book, but the later ones, containing accounts of the deposits in which recent plants have been found and of the positions of these plants.

*A Manual of Marine Meteorology for Apprentices and Officers of the World's Merchant Navies.* By William Allingham. Pp. viii + 182, and plates. (London: Charles Griffin and Co., Ltd., 1900.)

WE gladly give a word of welcome to this little book, written as it is by a sailor with the view of winning an increase of interest in the subject of meteorology from members of his own profession. The author knows well those for whom he is writing, so that while he has kept his book free from pedantry, he has managed to fill it with practical information and to endow it with the spirit of earnest purpose. The encouragement of a more complete survey of the complicated phenomena manifested, not only in our atmosphere, but in the ocean itself, is highly commendable, and we should imagine the author well qualified by knowledge and experience to interest the class to whom he mainly addresses himself. For he has sailed every ocean in all sorts of weather, and having himself to some extent profited by the systematised experience of others, he seeks now to widen and complete the circle of observation, so that those who come after may have still more trustworthy sources of guidance and readier means for escaping the perilous chances of navigation.

Of course, in many respects marine meteorology goes hand in hand with meteorological inquiries conducted on shore. We may pass over all such details, since the real interest of the book is more closely connected with the practical questions which arise at sea. Among these we may enumerate wave-motion, salinity and temperature of the sea, the direction and velocity of ocean currents, and the construction and use of pilot charts. Such subjects ought to have a profound interest for an intelligent officer, and the method of treatment is likely to call forth the earnest attention of any one who wishes to become really efficient. Some of these subjects may be thought to belong rather to hydrography than to meteorology; while, again, questions connected with the behaviour of the wind in cyclones, and of the management of the ship in the neighbourhood of cyclonic disturbances, may be said to belong to the domain of seamanship or practical navigation. But there is no fixed line of demarcation between any of these subjects, and trained intelligence is of the greatest service in advancing our knowledge of subjects in which experiment and generalisation play a great part. One can easily conceive that enormous advantages would accrue to science by enlisting the services of a large army of observers, and therefore we welcome any well-considered effort which has for its end so worthy an object. The author knows perfectly well that it is impossible to do justice, within a moderate compass, to the many topics on which he touches; but his object is served, and well served, if he can arouse an active interest in the many, and induce a few to prosecute inquiries on a more comprehensive basis.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### A Surface-tension Experiment.

SANS rien vouloir enlever à l'interêt de l'experience d'hydrodynamique signalée par Mr. Baker (p. 196), je crois pouvoir dire qu'elle n'est pas nouvelle, au moins, en tant que phénomène.

Ces sortes de formations de "vasques" liquides etaient très usitées, dans les jardins au XVII$^{\text{eme}}$ siècle et nous en rencontrons encore aujourd'hui des exemples dans les parcs où le régime des eaux n'a pas changé depuis cette époque. Pour n'en citer qu'un, que connaissent sans doute beaucoup de vos lecteurs, je rappelerai qu' à Burgos le "paseo del Espalon viejo" possède une fontaine où l'on peut voir une belle réalisation de cette experience. Seulement, là le jet d'eau est dirigé de bas en haut et vient se briser sur un disque placé horizontalement au dessus de lui; puis retombant, il forme autour du tuyau la surface *fermée* si élégante décrite par M. Baker.

Je crois me souvenir que dans un ouvrage publié en 1663 à Nuremberg par George André Boeckler sous le titre "Architectura curiosa nova," il y a de nombreuses planches représentant des jets d'eau d'effets très variés. Peut-être la forme signalée par Mr. Baker s'y trouve-t-elle?

Il serait intéressant de le vérifier, comme aussi de chercher la figure mathématique de cette surface fermée.

HENRY BOURGET,
de l'Université de Toulouse.

### Duration of Totality of Solar Eclipses at Greenwich.

IN NATURE (vol. lxii. p. 64 and p. 86) will be found an estimate of the maximum duration of totality for a solar eclipse under the most favourable conditions, the result being 7m. 40s for a place in north latitude 4° 52′. For Greenwich I estimate the maximum duration at 5m. 47s. There is good evidence for believing that the "Nautical Almanac" diameter of the moon, used in computing eclipses, is too large. It is almost exactly 2160 miles, and should be reduced probably to 2158 miles. This reduction would alter the above estimates to 7m. 34s. and 5m. 42s. respectively. That all the conditions necessary to produce the maximum totality of 5m. 42s. will ever be simultaneously satisfied for Greenwich is extremely improbable.

Leeds, July 14. CHAS. T. WHITMELL.

## *THE NEW YORK MEETING OF THE AMERICAN ASSOCIATION.*

AT the forty-ninth meeting of the American Association for the Advancement of Science, which was held on June 23-30, at Columbia University, New York City, two experiments were tried. The one was a change of date and the other a somewhat radical change in the character of the meeting. Heretofore, it may be remembered, the American Association has met at about the third week in August, approximately at the same time as the meeting of the British Association. The long summer vacation of the American colleges and universities usually lasts from about the end of June until nearly the beginning of October. It therefore resulted that men engaged in educational work were obliged to interrupt their summers at the seaside or the mountains, to attend the Association meetings. This has been found to be very inconvenient to many on account of the long distances in the States and the widely separated places of meeting. The present year was thought to be a particularly favourable one in which to try a change of date, since many members expected to start for Europe after the close of their college terms, and New York, as the principal port of debarkation, was chosen as the place of meeting for much the same reason.

The other experiment was in the doing away, to a large extent, with the social features and entertainments which had characterised previous meetings. It was distinctly understood that no entertainment fund would be raised in New York, and that the Association would pay its own expenses. It was, therefore, a more distinctively working scientific meeting than has been held before. The attendance was not large, and only 450 members registered. Fifteen affiliated societies held their meetings at the same time, including several which have heretofore not affiliated themselves with the older society. These were the American Mathematical Society, the American Physical Society, and the American Psychological Association. The other societies in attendance were the American Forestry Association, the Geological Society of America, the American Chemical Society, the Society for the Promotion of Agricultural Science, the Association of Economic Entomologists, the Botanical Society of America, the Society for the Promotion of Engineering, Education, the American Folk-Lore Society, and the American Microscopical Society.

The session was opened by the retiring President, Mr. G. K. Gilbert, who was elected at the December meeting of the Council to fill the vacancy caused by the death of Dr. Edward Orton last autumn. Mr. Gilbert introduced the incoming President, Prof. R. S. Woodward, of Columbia University, who thereafter presided over all the general sessions of the Association. A cordial and eloquent address of welcome was made by Mr. Seth Low, President of Columbia University; and Mr. James Wilson, the Secretary of Agriculture in President McKinley's Cabinet, upon being invited to address the Association, made a strong plea for applied science. On Tuesday afternoon the addresses of five of the Vice-Presidents were given, the other four being postponed until next year.

Vice-President Asaph Hall, junr., addressed the Section of Mathematics and Astronomy on the teaching of astronomy in the United States. Prof. Hall urged that elementary astronomy should be taught in the high schools and preparatory schools as well as in the colleges. Elementary astronomy he defines as meaning such part of the science as can be learned by an intelligent student without mathematical training. He advocated the study of the history of astronomy as a culture study in the colleges, showing that the earliest religious festivals depended upon astronomical observations. An interesting feature of this historical side would be the philosophical study of the different theories of the universe. He advocated the more general teaching of spherical astronomy and the elements of celestial mechanics, and showed that during the past twenty years great advances in astronomical teaching have been made in the States. In his opinion the best equipped observatory for teaching purposes is at Princeton, and the theses in practical astronomy produced in America compare favourably with those presented in Germany and France.

Vice-President Merritt addressed the Section on Physics on the subject of "Kathode Rays and some Related Phenomena," referring to the various views which have been advanced concerning the nature of the kathode rays, and the general adoption of the Crookes' theory of electrified particles. He gave an account of the progress made during the last ten years, and discussed recent experiments concerning the size of the ray particles and the speed at which they travel. Minor difficulties in the present theory were pointed out, and the probable direction of further progress was indicated. Lantern views were shown illustrating various vacuum tube phenomena related to kathode rays.

The address of Vice-President Howe before the Section of Chemistry was on the subject, "The Eighth Group of the Periodic System and some of its Problems." It was pointed out that in the early work of Newlands and of Mendeléeff, which subsequently developed into the periodic law, a serious difficulty was met with in dealing with iron, cobalt, nickel, and the metals of the platinum group.

In his first summing up of the principles of the periodic law in 1869, Mendeléeff concludes that "elements which are similar as regards their chemical properties have atomic weights which are either of nearly the same value (*e.g.* platinum, iridium, osmium) or which increase regularly (*e.g.* potassium, rubidium, cæsium)." So in most schemes for representing the periodic system, each triplet of these elements is considered as a single element, and because even then they do not seem to fall into regular periodic arrangement, they are cast out, Ishmael-like, into an anomalous eighth group. This is doubtless the reason they have been relatively so much neglected by chemists, and possibly it is not incorrect to say that the chemistry of these metals is less known than that of any other group of well characterised elements. Yet there are certainly no nine nearly related elements which present so many interesting chemical problems, the solution of which will so much further our knowledge of chemistry in general. Prof. Howe dealt in detail with this eighth group and some of its many problems.

The ordinary division of these nine metals is into three groups, viz., the common metals, iron, cobalt and nickel, with an atomic weight of from 56 to 59 and a specific gravity of 7·8 to 8·9; the lighter platinum metals, ruthenium, rhodium and palladium, with an atomic weight 101·5 to 106·5 and a specific gravity of about 12; and the heavy platinum metals, osmium, iridium and platinum, of atomic weight 191 to 195 and specific gravity 21·5 to 22·5. These nine metals are held to fulfil every definition of an element, and are just as much to be looked upon as simple elementary substances as any of those substances which are called elements. Though refined determinations may change, to a slight extent, the atomic weights of some of these elements, especially those of ruthenium and osmium, the weights of these elements relative to each other, and hence their position in the periodic system, will probably remain unchanged. This carries with it the conclusion that in the periodic table an element may have an atomic weight slightly lower than that of the element which precedes it.

Reference was made to the natural grouping of the elements of the eighth group into three triplets, iron, ruthenium, osmium; cobalt, rhodium, iridium; and nickel, palladium, platinum. That this is a natural grouping is attested by a comparison of the compounds of these metals. However, in considering now some of these compounds, the evidence of this grouping is only incidentally presented; Prof. Howe directed attention to some of the more unusual of these compounds, especially with reference to problems which this group presents, and to problems of other groups, suggested by the chemistry of this group.

Vice-President Kemp, before the Section of Geology and Geography, spoke upon the "Pre-Cambrian Sediments in the Adirondacks." He showed that the Adirondack area of ancient crystallines in Northern New York covers about 12,000 square miles. It has long been known that in the gneisses and eruptive rocks which constitute it, crystalline limestones of undoubted sedimentary origin occur in many places. The address presented the results of the work of the last ten years upon these sediments. It has been recently learned that ancient sandstones are also present, and many gneisses, which are doubtless altered shales. The crystalline limestones are in greatest individual areas in the north-west, where the belts have been shown to be from twenty to thirty-five miles long and from two to six miles broad; but they are most numerous on the east, where the speaker has now located over fifty different localities of relatively thin beds. In their structural relations these narrow beds on the east are interstratified with the gneisses, and are more especially associated with fragmental sediments. From these relations the argument is drawn that the sediments were extensive, that they involved more limestone on the west and more sandstone and shale on the east, and that many gneisses represent former shales. It was further shown that these strata are profoundly metamorphosed, and in such a way that the changes must have been produced while the rocks were under a heavy over-lying load, and were deeply buried. Evidence was brought forward to prove that this burden consisted of pre-Cambrian rocks. The speaker said that, inasmuch as there are abundant eruptive rocks present of a coarsely crystalline type, which were likewise produced under deep-seated conditions, it is assumed that they represent the deeper rocks of an old and very extensive volcanic area, whose tufas and lavas built up the burden of pre-Cambrian rocks, which have now disappeared, and which made possible the metamorphosis of the ancient sediments.

Vice-President Trelease, before the Section of Botany, delivered an address under the title, "Some Twentieth Century Problems," passing in review the great utilitarian development of botanical science during the present century, and indicating its probable greater advancement along utilitarian lines during the next hundred years. He made a general statement of the great problems to be met and solved, and considered in detail the necessity and means of co-operation in the treatment of species and their nomenclature, and in details of publication which are becoming daily of more evident importance for the greatest possible advancement of science. In conclusion he made a strong plea for the establishment of a Government Reservation in the Redwood (*Sequoyia sempervirens*) Forests in California, not only as a means of preserving a forest growth which can never be reproduced, but as furnishing the means of solving many problems closely connecting biology and meteorology, which may ultimately be of the greatest economic utility.

The address of the retiring President, Mr. G. K. Gilbert, was delivered on Tuesday evening at the American Museum of Natural History. His subject was "Rhythms and Geologic Time." This address appears in another part of the present number of NATURE.

The programmes of the sectional meetings were very full, and the discussions in the sections of mathematics and astronomy, physics, chemistry and botany were especially animated and prolonged.

Several important matters were decided upon by the Council. Perhaps that of the greatest general interest to members of the Association was the decision to try the experiment during the year beginning January 1, 1901, of publishing all official notices and proceedings of the Association in the journal *Science*, and of sending that journal to all members of the Association at the expense of the Association itself, and without charge to members beyond their annual dues. This will not make *Science* precisely the official organ of the Association, since the management and the editor will remain as before, and the Association will have no strict supervision of the conduct of the journal. The annual volume of proceedings will be reduced during that year, and possibly for future years, should the experiment prove a success, to a business record of the affairs of the Association, including lists of members and fellows, the text of the constitution, and possibly a list of the papers presented at the meetings.

Amendments to the constitution were adopted, establishing a new section of Physiology and Experimental Medicine (Section K), and lengthening the term of office of the Treasurer of the Association from one year to five. A discussion of the new International Association for the Advancement of Science, Art and Education was introduced, and conservative action was taken which simply expressed approval of the idea of international co-operation in the field of science, and promised to designate a delegate to a national conference having that end in view.

Grants were made to the Committee on Anthropometric Measurements; to the Committee on the Quantitative Study of Biological Variation; to the Committee on the Study of Blind Vertebrates; and to the Committee on Study of the Relation of Plants to Climate. The last two committees were established at this meeting. The one on Blind Vertebrates consists of Mr. Theodore N. Gill (chairman), Messrs. A. S. Packard, C. O. Whitman, S. H. Gage, H. C. Bumpus and C. H. Eigenmann. The one on Relation of Plants to Climate consists of Messrs. Wm. Trelease, D. T. MacDougall and J. M. Coulter.

Resolutions were adopted urging upon the Government of the United States (1) the establishment of a bureau of standards in connection with the U.S. Office of Standard Weights and Measures; (2) the establishment of a Government Reservation in the Primeval Redwood Forest, situated in the Santa Cruz Mountains in California; and (3) the establishment of a Government Reservation in some portion of the hard wood forests of the Southern Appalachian region.

At the meeting of the General Committee held on the evening of the June 28, the city of Denver, Colorado, was chosen as the place for the next meeting, and the time selected was the week ending August 31. The choice of Pittsburg, Pa., as a meeting place in 1902 was recommended by formal resolution.

On the same evening the following officers for the ensuing year were elected:—For President, Prof. Charles Sedgwick Minot, of the Harvard Medical School; for Vice-Presidents, as follows:—Section A, Mathematics and Astronomy, Prof. James MacMahon, of Cornell University; Section B, Physics, Prof. D. T. Brace, of the University of Nebraska; Section C, Chemistry, Prof. John H. Long, of the North-western University; Section D, Mechanical Science and Engineering, Prof. H. S. Jacoby, of Cornell University; Section E, Geology and Geography, Prof. C. R. Van Hise, of the University of Wisconsin; Section F, Zoology, Prof. D. S. Jordan, of Stanford University; Section G, Botany, Mr. B. T. Galloway, of the U.S. Department of Agriculture; Section H, Anthropology, Mr. J. Walter Fewkes, of the Bureau of American Ethnology; Section I, Social and Economic Science, Mr. John Hyde, Statistician, U.S. Department of Agriculture. General Secretary, Prof. Wm. Hallock, Columbia University; Secretary to the Council, Dr. D. T. MacDougall, New York Botanical Gardens.

## *THE WELLCOME RESEARCH LABORATORIES.*

IT is a remarkable sign of the times when the head of a firm principally distinguished for the introduction into this country of American methods of dealing with drugs, *i.e.* by putting them up in new and convenient shapes and doses, goes out of his way to fit up extensive research laboratories. This is what Mr. Wellcome has done. In 1896 laboratories were established in the business premises of the firm in Snow Hill. Now, after four years, during which the work continued to grow, it has been found necessary to give a complete house to the department. A well-built modern house has been secured at No. 6 King Street, Snow Hill, and has been converted into a series of three commodious and well-fitted laboratories, a library and office, and a store-room and workshop-laboratory. Each laboratory is self-contained, and each is connected with the other and with the directors' office by means of telephones. The basement contains a good-sized electric motor, and a dark room for polarimetric and photographic work. Use has been made of the electric mains to heat radiators for the distillation of ether, benzene and other inflammable liquids. The whole is under the direction of Dr. T. B. Power, F.I.C., who has a staff of four assistants, all men who have been carefully selected for their attainments and skill in actual research.

Mr. Wellcome is to be congratulated on his enterprise. His firm, considering the nature of their business, might well have acted on the supposition that research was not strictly within their province. They might have argued, "Research is the business of the drug manufacturer and the manufacturing chemist; it does not concern the compounder of medicines." Their success in former years is a solid argument in favour of such a view, which can be very easily strengthened by a consideration of the success of many firms who have pursued an exactly similar line of business.

Mr. Wellcome intends to carry on his laboratories in no narrow spirit; this means, I presume, that he has other views than the conversion of his business into a chemical manufacturing concern. Though much work is done towards the perfection of the firm's preparations, time has been found for several researches which have been published, and other work of this kind is in hand. At present the bulk of the work is carried out on the natural drugs, very little having been undertaken in the direction of investigations leading to the discovery or further knowledge of the properties of artificial medicinal substances. There is undoubtedly a vast field in the direction so far pursued, but every one must hope that the other will not be neglected, and that at length this country may make a contribution to the number of substances of medicinal value derived directly and not through the medium of plant or other life from the carbon compounds of the aromatic series.

The laboratories were informally opened on June 18, when at Mr. Wellcome's invitation a number of gentlemen interested in science, together with some representatives of the Press, were received by Dr. Power and conducted over the building. All interested in the advance of chemistry, whether pure or applied, will wish Mr. Wellcome success, and also that he may find imitators among the numbers of firms who are meditating an advance in the direction of a more scientific method of conducting their manufactures. R. J. FRISWELL.

## *NOTES.*

IN the House of Commons on Tuesday, Mr. Goschen announced that a committee of experts would be appointed to inquire into the efficiency of water-tube boilers in actual operation in different types of ships of H.M. Navy.

THE Additional Estimate for the Navy for the year 1900-1901 includes 9500*l.* for wireless telegraphy apparatus; 3600*l.* for telescopic sights for quick-firing guns; and 16,500*l.* for gyroscopes for Whitehead torpedoes.

THE scientific congresses to be opened in connection with the Paris Exposition during the present month are:—July 19-25, applied mechanics; July 23-28, applied chemistry; July 19-21, naval architecture and construction; July 28-August 3, navigation; July 28-August 4, chronometry; July 23-28, photography; July 18-21, homœopathy; July 23-28, professional medicine; July 27-29, medical press; July 27-August 1, electrology and medical radiology.

WE have been notified that the title of the subject for discussion at the joint meetings of the Institution of Electrical Engineers and the American Institute of Electrical Engineers to be held in the American Pavilion in the Paris Exhibition on the morning of Thursday, August 16, is "The relative advantages of alternate and continuous current for a general supply of electricity, especially with regard to interference with other interests." We understand it is specially desired to discuss how far interference with other undertakings, rather than ordinary commercial and industrial conditions, will come to be a determining factor in the selection between continuous and alternating currents. It is expected that many members of the American Institute will spend a few days in London on their way to the joint meeting in Paris. Arrangements are being made to entertain the visitors, and it is hoped that a large number of the British members will assist in making the visit a memorable one.

A CIRCULAR-LETTER has, this week, been addressed to the students of the Institution of Electrical Engineers informing them that the Council of the Institution propose to grant 5*l*. to each of twenty selected students to assist them to visit the electrical exhibits in the Paris Exhibition. Intending candidates must send in their applications by Saturday, July 28. In the selection, the Council will give preference, other things being equal, to those who, being still students of the Institution, have either, or both, read papers before the students' section, or been members of the committee of that section.

THE Paris Société d'Encouragement has awarded the following medal and prizes:—Gold medal to M. Potier for his work in physics; 2000 francs to M. Codron for his works on machine tools; 2000 francs to MM. Charabot Dupont and Pilet for their work on essential oils; 500 francs to M. Halphen for his work on the analysis of fatty bodies, and to M. Blanc for his work on the constitution of camphor; 500 francs to M. Granger for his study of the application of tungsten blue to ceramics; and 1000 francs to MM. Coudon and Boussard for their study of the potato.

THE Paris correspondent of the *Chemist and Druggist* announces that the late M. Milne-Edwards, director of the Paris Museum of Natural History and professor of zoology at the Paris School of Pharmacy, has bequeathed his scientific library, which is exceptionally complete and valuable, to the Paris Museum. The books are to be sold, and the proceeds will be applied towards maintaining the professorship of zoology, which the deceased *savant* occupied with so much distinction. M. Milne-Edwards also bequeathed 20,000 francs to the Paris Geographical Society, of which he was president, and 10,000 francs to the Société des Amis des Sciences.

FOR several days in last week the weather was very warm over a large part of England, and in London the temperature frequently exceeded 80°. This week the temperature has still further increased, and on Monday the thermometer in the screen registered 94° at Greenwich, which is the highest reading in July since 1881, and is higher than in any summer since 1893, while in all there have only been seven days during the last sixty years with so high a temperature there. At Camden Town the shade temperature registered 95°·2, the highest reading there since 1858. Thunderstorms developed at the beginning of the week over a large part of the country, but no appreciable amount of rain has fallen in London for about a fortnight.

WE learn from *Science* that it is proposed to celebrate the 70th birthday of Prof. Wilhelm Wundt, which will occur on August 16, 1902, by the publication of a "Festschrift," to which his former students are invited to contribute. The manuscripts must be forwarded to Prof. Külpe, Würzburg, not later than January 1, 1902.

IT was recently stated in the public press that postal packets containing plants for transmission to England were refused at Swiss post-offices on the ground that the plants would not be permitted to enter England. The Board of Customs has, however, just stated that there is no objection to the importation of plants from Switzerland, if they are sent by parcel post or letter post. But plants must not be sent by sample post, and the refusal of packets presented for transmission as samples appears to have produced the impression that the importation of flowers is not allowed.

AN exhibition and conference and other meetings will be held at the Crystal Palace, Sydenham, on July 20 and 21, in celebration of the bicentenary of the introduction of the sweet pea to Britain from Sicily in 1700. Some authorities hold that two forms, having a general relationship one to the other, were introduced, one from Sicily and the other from Ceylon. The history of the sweet pea and its earlier development will be dealt with at the conference meetings which are to be held in connection with the celebration. Many foreign horticulturists are giving the celebration their support in various ways; and one of the papers at the conference will deal with the culture and development of the sweet pea in the United States, where many fine varieties have been cultivated.

THE *Times* states that the construction of the vessel designed by Mr. W. E. Smith, one of the chief constructors to the Admiralty, for the National Antarctic Expedition, is now in active progress at the yard of the Dundee Shipbuilders' Company. The ship, which is to be named the *Discovery*, is to be barque-rigged and to have three decks. Accommodation for those on board will be provided under the upper deck. The stem will be of the ice-breaker type, with strong fortifications. The length of the vessel between perpendiculars is 172 feet; beam, 34 feet, and depth, 19 feet. The timbers are of oak dowelled and bolted together, and the keel, deadwoods, the stem, and the stem-posts are also of oak. The planking is of American elm and pitch pine, and the inside beams are of oak. With the object of avoiding the magnetic influence of iron on the scientific instruments on board, it has been decided that for a considerable radius amidships the knees and fastenings shall be of naval brass. In case the *Discovery* should have to winter in the ice, a heavy waggon cloth awning of strong woollen felt is to be provided. The fittings and equipment of the vessel will be of the most modern type. The engines, which are to indicate 450-horse-power, are to be constructed by Messrs. Gourlay Brothers and Co., Dundee.

NEWS has just reached this country of the death of a well-known geologist, Prof. G. H. F. Ulrich, F.G.S., who, since 1878, held the position of director of the School of Mines connected with the Otago University, New Zealand. Prof. Ulrich fell from a cliff while gathering rock specimens at Port Chalmers, and the injuries he received terminated fatally. Prof. Ulrich was born at Clausthal-Zillerfeld, Germany, in 1830, and was educated in his native town at the High School, and subsequently graduated at the Royal School of Mines, Clausthal, Hartz. He went to Forest Creek, Victoria, in 1854, and was appointed in 1857 assistant secretary and draughtsman to the Royal Mining Commission in Victoria. He was afterwards appointed assistant field geologist under Mr. Selwyn in the Geological department of Victoria. He continued an officer of the Geological Survey department until its abolition in 1869, when he became curator of the mining section under Mr. Newbery, superintendent of the industrial and technological museum and lecturer in mining at the University of Melbourne. He was appointed by the South Australian Government to report on their copper mines and goldfields, and in 1875 he paid his first visit to New Zealand and reported on the Otago goldfields. In 1877, the Otago University Council having decided to institute a school of mines, the Chancellor secured the services of Prof. Ulrich for the Otago University. The School of Mines was for some years small, and not very fully equipped, but in 1887 additional lecturers were appointed, and as the advantages of the course came to be appreciated, the number of students increased rapidly, and the attendance is now very large. Through the energy of Prof. Ulrich the models and appliances which had been procured from time to time became a valuable collection, especially in the mineral department, to which he was constantly adding from his own private collections of minerals and stones.

THE Committee on Indexing Chemical Literature presented their report of progress at the recent meeting of the American Association. From it we learn that Dr. Alfred Tuckerman has completed and sent to the Smithsonian Institution a supplement to his index to the literature of the spectroscope, which covers the period from 1887 to 1899. Dr. H. Carrington Bolton's second supplement to his select bibliography of chemistry, containing a list of 7500 chemical dissertations, is passing through the press; it will form a volume of the Smithsonian Miscellaneous Collections. Mr. A. G. Smith, of Cornell University, is engaged on an index to the literature of selenium and tellurium, which, it is expected, will be completed this summer. Dr. Frank I. Shepherd proposes to make a bibliography of the alkaloids. Mr. Frank R. Fraprie contemplates preparing an index to the literature of lithium.

IN the *Revue Générale des Sciences*, M. Louis Olivier gives some further particulars of Poulsen's "telegraphone," which is attracting attention at the Paris Exhibition. He describes several devices for increasing the volume of sound, or "intensifying" the record, to use the language of the photographer. The steel band with the consequent poles, which forms the original record, is made to pass between the poles of an electromagnet, which transfers the record to another band. This may be done several times over, and the record taken simultaneously from all the bands. In another arrangement the record is intensified by passing it very rapidly through the second magnetic field, which, as we know, has the effect of increasing the induced currents, and therefore also the intensity of the secondary record.

A NOVEL type of Newton's rings is described by Mr. A. C. Longden in the current number of the *American Journal of Science*. They are prepared by exposing a glass plate to the kathode rays emitted from a small globule of selenium. The film thus deposited is thickest at the point exactly opposite the globule, and tapers off towards the sides. The result is a film in the shape of a very flat lens, the upper and lower surfaces of which reflect light somewhat in the same manner as the upper and lower surfaces of the air film in Newton's device, with the difference, however, that in Mr. Longden's arrangement the film tapers outward instead of inward. Hence the rings increase in breadth and brilliancy away from the centre, and the order of the colours is reversed. The effect is described as very pretty.

THE annual list of the staffs of the Royal Gardens, Kew, and of botanical departments and establishments at home, and in India and the Colonies, in correspondence with Kew, has just been issued as an appendix to the *Bulletin of Miscellaneous Information*. We notice that sixty-six of the officers of the various botanic gardens have been trained at Kew, and seventeen others were appointed on the recommendation of the director of the Royal Gardens. With so many efficient observers distributed over our possessions it is not surprising that Kew is able to be of great service to the Empire as well as to science.

PLAGUE has now been established in Sydney for several months, and in an address delivered before the New South Wales Branch of the British Medical Association, Dr. Frank Tidswell of Sydney recently discussed a variety of interesting questions relating to the disease. Referring to his remarks on rats, the *Lancet* points out that there are instances which show that the presence of a plague-rat is often responsible for the illness in man. For example, a number of dead rats found one morning in a cotton factory at Bombay were removed by twenty coolies. Within the three following days about half of them fell sick with plague, whilst those in the store who had not touched the rats were not affected. Again, the coachman of an English family in Bombay found a dead rat in a stable and removed it. Three days later he fell sick with plague and died in a few hours, no other person in the same house being affected. Many persons, however, have caught plague without handling plague rats, and many persons have handled plague rats without catching plague. To explain this difficulty Simond has suggested that the infection is carried by the fleas natural to the rats. Perfectly healthy rats harbour very few fleas, and are very expert in removing them, but fleas are abundant on sick rats. After death, as the body becomes cold, the fleas leave it. In this way Simond accounted for the fact that a plague rat may be handled with impunity some hours after death. If the fleas from the dead rat reach another rat or a human being, they may inoculate the bacilli they acquired by ingesting the blood of their former host. In some of Simond's experiments sick and healthy rats in separate cages were enclosed in a glass jar, and it was found that when no fleas were present the healthy animals did not become infected.

COLOUR photometry is a subject that Sir William Abney has made his own, and in his last communication to the Royal Society he describes a method of estimating the luminosity of coloured surfaces that is especially applicable when the source of light is a large surface, such as the sky. In "Colour Photometry, Part iii." it was shown that only one ray of the spectrum, a greenish-yellow, progressed in luminosity at the same rate as white light. If, for example, red, greenish-yellow, blue and white lights are made of equal luminosity, and the illuminating beams are simultaneously and equally reduced in intensity, the luminosity of the red will diminish the most rapidly, that of the blue the least rapidly, the other two remaining equal. Moreover, the colour disappears more quickly than the luminosity (except in the case of pure red), tending towards greyness, so that colours of feeble luminosity are more easy to match than bright colours. The new method of colour photometry is based upon these facts. By means of concentric rotating discs, which are, when necessary, slit radially and interlaced, the proportion of black and white that matches first a green and then a yellow disc is determined. The comparisons are facilitated by observing the rotating discs through a "black transparent medium," such as an unstained developed photographic film, which may be so dense that the colour practically disappears, giving place to a dull grey. The value of a red disc is ascertained by interlacing it with the green and blue discs to produce a grey, which is then matched with the black and white. Thus, having three standard colours of known values, the luminosity of any other colour can be ascertained by substituting a disc of it for one of the standard colours to produce a grey, and matching the grey as before. The results given by this method agree closely with those obtained by the method previously described by the author. Sir William Abney has in this way determined the luminosities of various coloured surfaces and calculated the amount of black necessary for each, so that they shall be reduced to equal luminosity. He has then prepared a disc divided into several annuluses, each partly coloured and partly black, so that when rotated the whole appears of equal luminosity when illuminated by the light for which it is calculated. By the selection of suitable colours such a disc is a very convenient and effective test for any defect in either the colour sensitiveness of a photographic plate, or in the coloured screen used to compensate its inherent deficiencies in this matter. For the rotating disc, which is equally luminous throughout, will give, when the negative is developed, an image of equal density throughout, if the sensitive plate and colour screen are properly adjusted to each other.

THE U.S. Weather Bureau has published a *Bulletin* (No. 29), entitled "Frost fighting," by Mr. A. G. McAdie. A bulletin on the same subject was recently issued by the Bureau, but it is believed that the more recent experiments made in California are sufficiently valuable to extensive fruit interests to justify this second publication, and that the loss due to frosts in that State, hitherto considered unavoidable, can be prevented. The problem is of a two-fold nature: accurate forecasting of the frost period, and efficient methods of raising the temperature at critical times. The various protective methods, based on irrigation, the production of cloud or fog, and devices for screening the fruit trees are photographically illustrated. Of all the methods proposed, with the exception of the use of wire screens, irrigation has the largest amount of evidence in its favour; hot water from a boiler is forced through a number of furrows, and the temperature of the air is heated by the rising of the water-vapour.

WE have received from the Rev. W. Sidgreaves a copy of the results of meteorological and magnetical observations at Stonyhurst College Observatory, near Blackburn, for the year 1899. This observatory is fully equipped with self-recording instruments, and has for many years published valuable observations both independently and in connection with the Meteorological Office. During the past year a special report of hourly rainfall from 1891 to 1898 was prepared for that office. Much attention is given to solar observations and to the connection of sun-spots with terrestrial phenomena. The movements of the upper clouds, and the determination of the magnetic elements, also occupy the special attention of the small available staff of the observatory. An appendix contains observations taken at St. Ignatius College, Malta.

IN a paper on malformed specimens of the common pond-mussel, published in the last issue of the *Journal of Malacology*, Mr. H. H. Bloomer shows that in certain instances this mollusc is able to repair severe injuries to the mantle-lobes, but cannot make good damage inflicted on the gills.

DR. H. L. BRUNER communicates to vol. xvi. No. 2 of the *Journal of Morphology* the results of observations on the hearts of lungless salamanders, in which it is shown that with the lungs disappears also the septum between the auricles of the heart. Since, however, the normal circulation is not yet fully understood, it would be premature to discuss the reason for this loss.

IN the June issue of the *American Naturalist*, Miss Rathbun continues her invaluable illustrated synopsis of North American invertebrates, dealing in this section with certain groups of crabs. It may be hoped that, when complete, this synopsis will be reissued in book-form.

THE phylogeny of the butterflies of the family Pieridæ (best known by the ordinary British "whites") is discussed by Mr. A. R. Grote in No. 161 of the *Proceedings* of the American Philosophical Society. The author is of opinion that the family is an offshoot from the Hesperiidæ, or skippers, which is itself related to the Nymphalidæ, and that the "blues" may likewise be another offshoot from the same stock. From the scant evidence afforded by fossil forms, it further seems evident that the blues and the whites are modern types of butterflies, while the skippers and the nymphalids are of greater antiquity.—Anthropologists will find considerable interest in a paper on the divisions of the South Australian Aborigines, by Mr. R. H. Mathews, which appears in the same serial.

IN a paper published in the *Comunicaciones* of the Buenos Aires Museum (vol. i. No. 6) Dr. F. Ameghino describes and figures certain mammalian remains from the areniscan formation of southern Patagonia. These remains are stated to be found in association with those of dinosaurs as well as of fishes of the genera Synechodus, Lepidotus and Ceratodus, and the formation is accordingly correlated with the lower Cretaceous of Europe and the United States. The mammalian remains are, however, of such a highly specialised type that it is almost impossible to believe they can be of such great antiquity; and it seems probable that some other explanation of their alleged association with Cretaceous types will have to be found.

WE learn from the *American Naturalist* that a school of applied agriculture and horticulture will be established near New York City, to open in September, for study and practical training. Students will have the use of the laboratories and of the extensive collection of plants in the museum and conservatories and in the grounds of the New York Botanic Garden. The work will be under the direction of Mr. George T. Powell.

THE following facilities for the practical study of biology during the summer vacation are offered in the United States, in addition to those already announced. The Biological Laboratory of the Brooklyn Institute of Arts and Sciences at Cold Spring Harbour, Long Island, will be open from July 1 to August 25, under the guidance of Prof. Davenport. The Lake Laboratory of the Ohio State University at Sandusky, Lake Erie, will be open for eight weeks from July 2. Four courses of lectures will be given in zoology, and three in botany. The Rhode Island summer school for nature study is holding its session at Kingston, R.I., from July 5 to 20. Beloit College, Wisconsin, will hold a summer school on Madeline Island, Lake Superior, from July 26 to Aug. 30. The natural science camp for boys will hold its eleventh session at Canandaigua, N.Y., under the management of Mr. Albert L. Arey. Instruction will be given in biology, entomology, taxidermy, and photography.

THE *Biologisches Centralblatt* for June 15 and July 1 contains a detailed biography of the late eminent diatomist, Comte Abbé F. Castracane, together with a complete bibliography of his very numerous contributions to botanical literature.

*Bulletin* No. 10 (February 1900) of the Michigan State Agricultural College Experiment Station (Agricultural Department), is devoted entirely to investigations in the cultivation of the sugar-beet, by Mr. J. D. Towar, chiefly in relation to the advantages of different soils and manures.

PROF. L. ERRERA reprints from the *Revue de l'Université de Bruxelles* a paper on spontaneous generation, one of a series of essays on botanical philosophy. After a historical account of the controversy, he sums up thus:—"Si donc la génération spontanée est encore irréalisée dans nos laboratoires, rien ne prouve qu'elle soit à jamais irréalisable."

WE have received the *Transactions* of the British Mycological Society for the season 1898–1899. It contains the address of the President, Dr. C. B. Plowright, on the recent additions to our knowledge of the Uredineæ and Ustilagineæ, with special reference to British species, a report of the New Forest fungus foray, and five papers on new or rare fungi.

THE economic geology of the United States is very amply dealt with in the larger reports of the Geological Survey, while individual States publish reports on particular subjects. One of these on the clays of Alabama, by Dr. E. A. Smith and Dr. H. Ries, has just reached us. The State yields china clay, fire clay, pottery clay, and brick clay, all of which are very fully described with regard to their characters, geological age and distribution, and a number of analyses are given. In addition to the local account, there is also a general discussion of clays, their chemical, physical and mineral characters, such as will be of great use to any one studying the subject from a scientific as well as economic point of view. Mention is made of beds of white pulverulent silica, which when mixed with clay has been used in the manufacture of a paint.

WE have received from the Geological Survey of Canada, Part 1 of a "Catalogue of Canadian Birds," by Mr. J. Macoren, dealing with water-birds, gallinaceous birds, and pigeons.

THE third volume of Prof. G. O. Sars's "Account of the Crustacea of Norway," dealing with the anomalous group Cumacea, is in course of publication by the Bergen Museum. Parts v. and vi., devoted to the Diastylidæ, have just been issued.

PART 10 of Memoir III. of the Australian Museum, Sydney, on "The Atoll of Funafuti" has now been issued. It is the concluding part of the memoir, and contains lists of the contributors and plates, and an index to the whole work.

MESSRS. ISENTHAL AND CO., have issued a revised edition of their list of apparatus and accessories for work with Röntgen rays. Particular attention is given by this firm to the design and construction of instruments for radiographic work, and any one contemplating an installation for this purpose will find the list just issued well worth examination.

THE additions to the Zoological Society's Gardens during the past week include a Patas Monkey (*Cercopithecus patas*, ♀) from West Africa, presented by Mr. W. B. Davidson Houston; a Rhesus Monkey (*Macacus rhesus*) from India, presented by Mrs. Heigham; a Common Marmoset (*Hapale jacchus*) from South-east Brazil, presented by Mrs. Alexander Grant; two Grey-headed Love-Birds (*Agapornis cana*) from Madagascar, presented by Mrs. Harry Blades; a Cuckoo (*Cuculus canorus*), European, presented by Mr. L. W. Wiglesworth; an Entellus Monkey (*Semnopithecus entellus*, ♀) from India, a —— Bear (*Ursus*, sp. inc.) from Kuldja, a Himalayan Snow Partridge (*Tetrogallus himalayensis*) from the Himalayas, two Brazilian Tortoises (*Testudo tabulata*) from South America, deposited; a Sharp-nosed Badger (*Meles leptorhynchus*) from China, a Rough Fox (*Canis rudis*) from South America, purchased; a Little Bittern (*Ardetta minuta*), European, received in exchange; a Brindled Gnu (*Connochoetes taurina*, ♀), an Altai Deer (*Cervus eustephanus*), born in the Gardens.

## *RHYTHMS AND GEOLOGIC TIME.*[1]

THE subject to which I shall invite your attention this evening is by no means novel, but might better be called perennial or recurrent; for the problem of our earth's age seems to bear repeated solution without loss of vigour or prestige. It has been a marked favourite, moreover, with presidents and vice-presidents, retiring or otherwise, when called upon to address assemblies whose fields of scientific interest are somewhat diverse—for the reason, I imagine, that while the specialist claims the problem as his peculiar theme of study, he feels that other denizens of the planet in question may not lack interest in the early lore of their estate.

The difficulty of the problem inheres in the fact that it not only transcends direct observation but demands the extrapolation or extension of familiar physical laws and processes far beyond the ordinary range of qualifying conditions. From whatever side it is approached the way must be paved by postulates, and the resulting views are so discrepant that impartial onlookers have come to be suspicious of these convenient and inviting stepping stones.

In giving brief consideration to each of the more important ways by which the problem of the earth's age has been approached, I shall mention first those which follow the action of some continuous process, and afterward those which depend on the recognition of rhythms.

The earliest computations of geologic time, as well as the majority of all such computations, have followed the line of the most familiar and fundamental of geological processes. All through the ages the rains, the rivers and the waves have been eating away the land, and the product of their gnawing has been received by the sea and spread out in layers of sediment. These layers have been hardened into rocky strata, and from time to time portions have been upraised and made part of the land. The record they contain makes the chief part of geologic history, and the groups into which they are divided correspond to the ages and periods of that history. In order to make use of these old sediments as measures of time, it is necessary to know either their thickness or their volume, and also the rate at which they were laid down. As the actual process of sedimentation is concealed from view, advantage is taken of the fact that the whole quantity deposited in a year is exactly equalled by the whole quantity washed from the land in the same time, and measurements and estimates are made of the amounts brought to the sea by rivers and torn from the cliffs of the shore by waves. After an estimate has been obtained of the total annual sedimentation at the present time, it is necessary to assume either that the average rate in past ages has been the same or that it has differed in some definite way.

At this point the course of procedure divides. The computer may consider the aggregate amount of the sedimentary rocks, irrespective of their subdivisions, or he may consider the thicknesses of the various groups as exhibited in different localities. If he views the rocks collectively, as a total to be divided by the annual increment, his estimate of the total is founded primarily on direct measurements made at many places on the continents, but to the result of such measurements he must add a postulated amount for the rocks concealed by the ocean, and another postulated amount for the material which has been eroded from the land and deposited in the sea more than once.

If, on the other hand, he views each group of rocks by itself, and takes account of its thickness at some locality where it is well displayed, he must acquire in some way definite conceptions of the rates at which its component layers of sand, clay and limy mud were accumulated, or else he must postulate that its average rate of accretion bore some definite ratio to the present average rate of sedimentation for the whole ocean. This course is, on the whole, more difficult than the other, but it has yielded certain preliminary factors in which considerable confidence is felt. Whatever may have been the absolute rate of rock building in each locality, it is believed that a group of strata which exhibits great thickness in many places must represent more time than a group of similar strata which is everywhere thin, and that clays and marls, settling in quiet waters are likely to represent, foot for foot, greater amounts of time than the coarser sediments gathered by strong currents; and studying the formations with regard to both thickness and texture, geologists have made out what are called *time ratios*—series of numbers expressing the relative lengths of the different ages, periods and epochs. Such estimates of ratios, when made by different persons, are found to vary much less than do the estimates of absolute time, and they will serve an excellent purpose whenever a satisfactory determination shall have been made of the duration of any one period.

Reade has varied the sedimentary method by restricting attention to the limestones, which have the peculiarity that their material is carried from the land in solution; and it is a point in favour of this procedure that the dissolved burdens of rivers are more easily measured than their burdens of clay and sand.

An independent system of time ratios has been founded on the principle of the evolution of life. Not all formations are equally supplied with fossils, but some of them contain voluminous records of contemporary life; and when account is taken of the amount of change from each full record to the next, the steps of the series are found to be unequal in magnitude. Though there is no method of precisely measuring the steps, even in a comparative way, it has yet been found possible to make approximate estimates, and these in the main lend support to the time ratios founded on sedimentation. They bring aid also at a point where the sedimentary data are weak, for the earliest formations are hard to classify and measure. It is true that these same formations are almost barren of fossils, but biological inference does not therefore stop. The oldest known fauna, the Eocambrian, does not represent the beginnings of life, but a well advanced stage, characterised by development along many divergent lines; and by comparing Eocambrian life with existing life the paleontologist is able to make an estimate of the relative progress in evolution before and after the Eocambrian epoch. The only absolute blank left by the time ratios pertains to an azoic age which may have intervened between the development of a habitable earth crust and the actual beginning of life.

[1] Abridged from an address to the American Association for the Advancement of Science, at New York, June 26, by the retiring President, Mr. G. K. Gilbert. By the courtesy of the Editor of *Science*, advance proofs of the address were received.

Erosion and deposition have been used also, in a variety of ways, to compute the length of very recent geologic epochs. Thus, from the accumulation of sand in beaches, Andrews estimated the age of Lake Michigan, and Upham the age of the glacial lake Agassiz; and from the erosion of the Niagara gorge the age of the river flowing through it has been estimated. But while these discussions have yielded conceptions of the nature of geological time, and have served to illustrate the extreme complexity of the conditions which affect its measurement, they have accomplished little toward the determination of the length of a geologic period; for they have pertained only to a small fraction of what geologists call a period, and that fraction was of a somewhat abnormal character.

Wholly independent avenues of approach are opened by the study of processes pertaining to the earth as a planet, and with these the name of Kelvin is prominently associated.

As the rotation of the earth causes the tides, and as the tides expend energy, the tides must act as a brake, checking the speed of rotation. Therefore the earth has in the past spun faster than now, and its rate of spinning at any remote point of time may be computed. Assuming that the whole globe is solid and rigid, and that the geologic record could not begin until that condition had been attained, there could not have been great checking of rotation since consolidation. For if there had been, it would have resulted in the gathering of the oceans about the poles and the baring of the land near the equator, a condition very different from what actually obtains. This line of reasoning yields an obscure outer limit to the age of the earth.

On the assumption that the globe lacks something of perfect rigidity, G. H. Darwin has traced back the history of the earth and the moon to an epoch when the two bodies were united, their separation having been followed by the gradual enlargement of the moon's orbit and the gradual retardation of the earth's rotation; and this line of inquiry has also yielded an obscure outer limit to the antiquity of the earth as a habitable globe.

One of the most elaborate of all the computations starts with the assumption that at an initial epoch, when the outer part of the earth was consolidated from a liquid condition, the whole body of the planet had approximately the same temperature; and that as the surface afterward cooled by outward radiation there was a flow of heat to the surface by conduction from below. The rate of this flow has diminished from that epoch to the present time according to a definite law, and the present rate, being known from observation, affords a measure of the age of the crust. The strength of this computation lies in its definiteness and the simplicity of its data; its weakness in the fact that it postulates a knowledge of certain properties of rock—namely, its fusibility, conductivity and viscosity—when subjected to pressures and temperatures far greater than have ever been investigated experimentally.

A parallel line of discussion pertains to the sun. Great as is the quantity of heat which that incandescent globe yields to the earth, it is but a minute fraction of the whole amount with which it continually parts, for its radiation is equal in all directions, and the earth is but a speck in the solar sky. On the assumption that this immense loss of heat is accompanied by a corresponding loss of volume, the sun is shrinking at a definite rate, and a computation based on this rate has told how many millions of years ago the sun's diameter should have been equal to the present diameter of the earth's orbit. Manifestly the earth cannot have been ready for habitation before the passage of that epoch, and so the computation yields a superior limit to the extent of geologic time.

Before passing to the next division of the subject—the computations based on rhythms—a few words may be given to the results which have been obtained from the study of continuous processes. Realising that your patience may have been strained by the kaleidoscopic character of the rapid review which has seemed unavoidable, I shall spare you the recitation of numerical details, and merely state in general terms that the geologists, or those who have reasoned from the rocks and fossils, have deduced values for the earth's age very much larger than have been obtained by the physicists, or those who have reasoned from earth cooling, sun cooling and tidal friction. In order to express their results in millions of years, the geologist must employ from three to five digits, while the physicists need but one or two. When these enormous discrepancies were first realised, it was seen that serious errors must exist in some of the observational data, or else in some of the theories employed; and geologists undertook with zeal the revision of their computations, making as earnest an effort for reconciliation as had been made a generation earlier to adjust the elements of the Hebrew cosmogony to the facts of geology. But after rediscussing the measurements and readjusting the assumptions so as to reduce the time estimates in every reasonable way—and perhaps in some that were not so reasonable—they were still unable to compress the chapters of geologic history between the narrow covers of physical limitation; and there the matter rests for the present.

The rocks which were formed as sediments show many traces of rhythm. Some are composed of layers, thin as paper, which alternate in colour, so that when broken across they exhibit delicate banding. In the time of their making there was a periodic change in the character of the mud that settled from the water. Others are banded on a larger scale; and there are also bandings of texture where the colour is uniform. Many formations are divided into separate strata, as though the process of accretion had been periodically interrupted. Series of hard strata are often separated by films or thin layers of softer material. Strata of two kinds are sometimes seen to alternate through many repetitions. Borings in the delta of the Mississippi show soils and remains of trees at many levels, alternating with river silts. The rock series in which coal occurs are monotonous repetitions of shale and sandstone. Belgian geologists have been so impressed by the recurrence of short sequences of strata that they have based an elaborate system of rock notation upon it.

Passing to still greater units, the large aggregates of strata sometimes called systems show in many cases a regular sequence, which Newberry called a "circle of deposition." When complete it comprises a sandstone or conglomerate, at base, then shale, limestone, shale and sandstone. This sequence is explained as the result of the gradual encroachment, or transgression as it is called, of the sea over the land and its subsequent recession.

In certain bogs of Scandinavia deep accumulations of peat are traversed horizontally by layers including tree stumps in such way as to indicate that the ground has been alternately covered by forest and boggy moss. The broad glaciers of the Ice age grew alternately smaller and larger—or else were repeatedly dissipated and reformed—and their final waning was characterised by a series of halts or partial readvances, recorded in concentric belts of ice-brought drift. Of these belts, called moraines of recession, Taylor enumerates seventeen in a single system.

In explanation of these and other repetitive series incorporated in the structure of the earth's crust, a variety of rhythmic causes have been adduced; and mention will be made of the more important, beginning with those which have the character of original rhythms.

A river flowing through its delta clogs its channel with sediment, and from time to time shifts its course to a new line, reaching the sea by a new mouth. Such changes interrupt and vary sedimentation in neighbouring parts of the sea. Storms of rain make floods, and each flood may cause a separate stratum of sediment. Storms of wind give destructive force to the waves that beat the shore, and each storm may cause the deposit of an individual layer of sediment. Varying winds may drive currents this way and that, causing alternations in sedimentation.

To explain the forest beds buried in the Mississippi silts it has been suggested that the soft deposits of the delta from time to time settled and spread out under their own weight. Various alternations of strata, and especially those of the Coal measures, have been ascribed to successive local subsidences of the earth's crust, caused by the addition of loads of deposit. It has been suggested also that land undergoing erosion may rise up from time to time because relieved of load, and the character of sediment might be changed by such rising. Subterranean forces, of whatever origin, seemingly slumber while strains are accumulating, and then become suddenly manifest in dislocations and eruptions, and such catastrophes affect sedimentation.

A more general rhythm has been ascribed to the tidal retardation of rotation and the resulting change of the earth's form. If the body of the earth has a rather high rigidity, we should expect that it would for a time resist the tendency to become more nearly spherical, while the water of the ocean would accommodate itself to the changing conditions of equilibrium by seeking the higher latitudes. Eventually, however, the solid earth would yield to the strain and its figure become adjusted to the slower rotation, and then the mobile water would return. Thus would be caused periodic transgressions by the sea, occurring alternately in high and low latitudes.

Another general rhythm has been recently suggested by Chamberlin in connection with the hypothesis that secular variations of climate are chiefly due to variations of the quantity of carbon dioxide in the atmosphere.[1] The system of interdependent factors he works out is too complex for presentation at this time, and I must content myself with saying that his explanation of the moraines of recession involves the interaction of a peculiar atmospheric condition with a condition of glaciation, each condition tending to aggravate the other, until the cumulative results brought about a reaction and the climatic pendulum swung in the opposite direction. With each successive oscillation the momentum was less, and an equilibrium was finally reached.

Few of these original rhythms have been used in computations of geologic time, and it is not believed that they have any positive value for that purpose. Nevertheless, account must be taken of them, because they compete with imposed rhythms for the explanation of many phenomena, and the imposed rhythms, wherever established, yield estimates of time.

The tidal period, or the half of the lunar day, is the shortest imposed rhythm appealed to in the explanation of the features of sedimentation. It is quite conceivable that the bottom of a quiet bay may receive at each tide a thin deposit of mud which could be distinguished in the resulting rock as a papery layer or lamina. If one could in some way identify a rock thus formed, he might learn how many half-days its making required by counting its laminæ, just as the years of a tree's age are learned by counting its rings of growth.

The next imposed rhythm of geologic importance is the year. There are rivers, like the Nile, having but one notable flood in each year, and so depositing annual layers of sediment on their alluvial plains and on the sea beds near their mouths. Where oceanic currents are annually reversed by monsoons, sedimentation may be regularly varied, or interrupted, once a year. Streams from a glacier cease to run in winter, and this annual interruption may give a definite structure to resulting deposits. It is therefore probable that some of the laminæ or strata of rocks represent years, but the circumstances are rarely such that the investigator can bar out the possibility that part of the markings or separations were caused by original rhythms of unknown period.

The number of rhythms existing in the solar system is very large, but there are only two, in addition to the two just mentioned, which seem competent to write themselves in a legible way in the geologic record. These are the rhythms of precession and eccentricity.

Because the earth's orbit is not quite circular and the sun's position is a little out of the centre, or is eccentric, the two hemispheres into which the earth is divided by the equator do not receive their heat in the same way. The northern summer, or the period during which the northern hemisphere is inclined toward the sun, occurs when the earth is farthest from the sun, and the northern winter occurs when the earth is nearest to the sun, or in that part of the orbit called perihelion. These relations are exactly reversed for the southern hemisphere. The general effect of this is that the southern summer is hotter than the northern, and the southern winter is colder than the northern. In the southern part of the planet there is more contrast between summer and winter than in the northern. The sun sends to each half the same total quantity of heat in the course of a year, but the difference in distribution makes the climates different. The physics of the atmosphere is so intricate a subject that meteorologists are not fully agreed as to the theoretical consequences of these differences of solar heating, but it is generally believed that they are important, involving differences in the force of the winds, in the velocity and course of ocean currents, in vegetation, and in the extent of glaciers.

Now, the point of interest in the present connection is that the astronomical relations which occasion these peculiarities are not constant, but undergo a slow periodic change. The relation of the seasons to the orbit is gradually shifting, so that each season in turn coincides with the perihelion; and the climatic peculiarities of the two hemispheres, so far as they depend on planetary motions, are periodically reversed. The time in which the cycle of change is completed, or the period of the rhythm, is not always the same, but averages 21,000 years. It is commonly called the precessional period.[1]

Assuming that the climates of many parts of the earth are subject to a secular cycle, with contrasted phases every 10,500 years, we should expect to find records of the cycle in the sediments. A moist climate would tend to leach the calcareous matter from the rock, leaving an earthy soil behind, and in a succeeding drier climate the soil would be carried away; and thus the adjacent ocean would receive first calcareous and then earthy sediments. The increase of glaciers in one hemisphere would not only modify adjacent sediments directly, but, by adding matter on that side, would make a small difference in the position of the earth's centre of gravity. The ocean would move somewhat toward the weighted hemisphere, encroaching on some coasts and drawing down on others; and even a small change of that sort would modify the conditions of erosion and deposition to an appreciable extent in many localities.

Blytt ascribed to this astronomical cause the alterations of bog and forest in Scandinavia, as well as other sedimentary rhythms observed in Europe; and it has seemed to me competent to account for certain alternations of strata in the Cretaceous formations of Colorado. Croll used it to explain interglacial epochs, and Taylor has recently applied it to the moraines of recession.

The remaining astronomical rhythm of geological import is the variation of eccentricity. At the present time our greatest distance from the sun exceeds our least distance by its thirtieth part, but the difference is not usually so small as this. It may increase to the seventh part of the whole distance, and it may fall to zero. Between these limits it fluctuates in a somewhat irregular way, in which the property of periodicity is not conspicuous. The effect of its fluctuation is inseparable from the precessional effect, and is related to it as a modifying condition. When the eccentricity is large the precessional rhythm is emphasised; when it is small the precessional effect is weak.

The variation of eccentricity is connected with the most celebrated of all attempts to determine a limited portion of geological time. In the elaboration of the theory of the Ice age which bears his name, Croll correlated two important epochs of glaciation with epochs of high eccentricity computed to have occurred about 100,000 and 210,000 years ago. As the analysis of the glacial history progresses, these correlations will eventually be established or disproved, and should they be established it is possible that similar correlations may be made between events far more remote.

The studies of these several rhythms, while they have led to the computation of various epochs and stages of geologic time, have not yet furnished an estimate either of the entire age of the earth or of any large part of it. Nevertheless, I believe that they may profitably be followed with that end in view.

The system of rock layers, great and small, constituting the record of sedimentation, may be compared to the scroll of a chronograph. The geological scroll bears many separate lines, one for each district where rocks are well displayed, but these are not independent, for they are labelled by fossils, and by means of these labels can be arranged in proper relation. In each time line are little jogs—changes in kind of rock or breaks in continuity—and these jogs record contemporary events. A new mountain was uplifted, perhaps, on the neighbouring continent, or an old uplift received a new impulse. Through what Davis calls stream piracy a river gained or lost the drainage of a tract of country. Escaping lava threw a dam across the course of a stream, or some Krakatoa strewed ashes over the land and gave the rivers a new material to work on. The jogs may be faint or strong, many or few, and for long distances the lines may run smooth and straight; but so long as the jogs are irregular they give no clue to time. Here and there, however, the even line will betray a regularly recurring indentation or undulation, reflecting a rhythm and possibly significant of a remote pendulum whose rate of vibration is known. If it can be traced to such a pendulum there will result a determination of the rate at which the chronograph scroll moved when that part of the record was made; and a moderate number of such determinations, if well distributed, will convert the whole scroll into a definite time scale.

---

[1] An attempt to frame a working hypothesis of the cause of glacial periods on an atmospheric basis. *Journ. Geol.*, vol. vii., 1899.

[1] Strictly speaking, 21,000 years is the period of the precession of the equinoxes as referred to perihelion; but the perihelion is itself in motion. As referred to a fixed star the precession of the equinoxes has an average period of about 25,700 years.

In other words, if a sufficient number of the rhythms embodied in strata can be identified with particular imposed rhythms, the rates of sedimentation under different circumstances and at different times will become known, and eventually so many parts of geologic time will have become subject to direct calculation that the intervals can be rationally bridged over by the aid of time ratios.

For this purpose there is only one of the imposed rhythms of practical value, namely, the precessional; but that one is, in my judgment, of high value. The tidal rhythm cannot be expected to characterise any thick formation. The annual is liable to confusion with a variety of original rhythms, especially those connected with storms. The rhythm of eccentricity, being theoretically expressed only as an accentuation of the precessional, cannot ordinarily be distinguished from it. But none of these qualifications apply to the precessional. It is not liable to confusion with the tidal and annual because its period is so much longer, being more than 2000 times that of the annual. It has an eminently practical and convenient magnitude, in that its physical manifestation is well above the microscopic plane, and yet not so large as to prevent the frequent bringing of several examples into a single view. It is also practically regular in period, rarely deviating from the average length by more than the tenth part.

From the greater number of original rhythms it is distinguished, just as from the annual and tidal, by magnitude. The practical geologist would never confuse the deposit occasioned by a single storm, for example, with the sediments accumulated during an astronomical cycle of 20,000 years. But there are other original rhythms, known or surmised, which might have magnitudes of the same general order, and to discriminate the precessional from these it is necessary to employ other characters. Such characters are found in its regularity or evenness of period, and in its practical perpetuity. The diversion of the mouth of a great river, such as the Hoang Ho or the Mississippi, might recur only after long intervals; but from what we know of the behaviour of smaller streams we may be sure that such events would be very irregular in time as well as in other ways. The intervals between volcanic eruptions at a particular vent or in a particular district may at times amount to thousands of years, but their irregularity is a characteristic feature. The same is true of the recurrent uplifts by which mountains grow, so far as we may judge them by the related phenomena of earthquakes; and the same category would seem to hold also the theoretically recurrent collapse of the globe under the strains arising from the slowing of rotation. The carbon dioxide rhythm, known as yet only in the field of hypothesis, is hypothetically a running-down oscillation, like the lessening sway of the cradle when the push is no longer given.

But the precessional motion pulses steadily on through the ages like the swing of a frictionless pendulum. Its throb may or may not be caught by the geological process which obtains in a particular province and in a particular era, but whenever the conditions are favourable and the connection is made, the record should reflect the persistence and the regularity of the inciting rhythm.

The search of the rocks for records of the ticks of the precessional clock is an out-of-door work. Pursued as a closet study it could have no satisfactory outcome, because the printed descriptions of rock sequences are not sufficiently complete for the purpose; and the closet study of geology is peculiarly exposed to the perils of hobby-riding. A student of the time problem cannot be sure of a persistent, equable sedimentary rhythm without direct observation of the characters of the repeated layers. He needs to avail himself of every opportunity to study the series in its horizontal extent, and he should view the local problem of original *versus* imposed rhythm with the aid of all the light which the field evidence can cast on the conditions of sedimentation.

Neither do I think of rhythm seeking as a pursuit to absorb the whole time and energy of an individual and be followed steadily to a conclusion; but hope rather that it may receive the incidental and occasional attention of many of my colleagues of the hammer, as other errands lead them among cliffs of bedded rocks. If my suggestion should succeed in adding a working hypothesis or point of view to the equipment of field geologists, I should feel that the search had been begun in the most promising and advantageous manner. For not only would the subject of rhythms and their interpretations be advanced by reactions from multifarious individual experiences, but the stimulus of another hypothesis would lead to the discovery of unexpected meanings in stratigraphic detail.

It is one of the fortunate qualities of scientific research that its incidental and unanticipated results are not unfrequently of equal or even greater value than those directly sought. Indeed, if it were not so there would be no utilitarian harvest from the cultivation of the field of pure science.

In advocating the adoption of a new point of view from which to peer into the mysterious past, I would not be understood to advise the abandonment of old standpoints, but rather to emulate the surveyor, who makes measurement to inaccessible points by means of bearings from different sides. Every independent bearing on the earth's beginning is a check on other bearings, and it is through the study of discrepancies that we are to discover the refractions by which our lines of sight are warped and twisted. The three principal lines we have now projected into the abyss of time miss one another altogether, so that there is no point of intersection. If any one of them is straight, both the others are hopelessly crooked. If we would succeed we should not only take new bearings from each discovered point of vantage, but strive in every way to discover the sources of error in the bearings we have already attempted.

## THE RELATION OF STIMULUS TO SENSATION.

NOTHING has done more to place on a scientific footing the discussion of the phenomena which the study of matter and energy presents to the eye of reason, than the establishment of a doctrine of quantitative equivalence. So much oxygen and hydrogen, so much water; this amount of energy of chemical separation gone, that amount of sensible heat gained. In a similar way, nothing is likely to do more to give support to the hypothesis that sentience or consciousness is a concomitant of certain physiological processes than the establishment of a quantitative relation between stimulus and sensation.

It has, indeed, long been obvious that some general relation of this kind holds good. Increased physical pressure is, within certain limits, increasingly felt; more light gives a higher degree of visual sensation; the greater the amplitude of the vibrations of a violin-string the fuller and louder the sound. Such statements are, however, indefinite. We want to know how much the physical increase must be to give just so much increment in sensation. If we double the strength of the stimulus, do we double also the strength of the sensation? If not, by how much do we increase it? Ernst Heinrich Weber sought to express the quantitative relation with some exactness; Gustav Theodor Fechner and other more recent inquirers have built upon the foundations laid by Weber; and a provisional law of the relation of physical stimulus to felt sensation has gradually gained wide acceptance.

Weber's classical experiments dealt with what is termed the "least observable difference." If, for example, a weight of one pound be laid upon the hand, it gives rise to a sensation of pressure. If, now, an extra ounce be added no difference is felt, nor is the added weight of two or of three ounces perceptible. The sensation is not increased, and then only just perceivably increased, till one-third of a pound is added. This, then, is said to be the least observable difference. We now start afresh with a load of two pounds, and add, as before, one-third of a pound. But there is no observable difference; nor is there any felt increase in sensation until two-thirds of a pound are added. Starting once more with an initial load of three pounds, we find that neither the addition of one-third, nor that of two-thirds of a pound affords any observable difference in the sensation experienced. A full pound must be added for the increment to be felt. The least observable differences, therefore, are between

1 lb. and $1 + \frac{1}{3}$ lb.
2 lb. ,, $2 + \frac{2}{3}$ lb.
3 lb. ,, $3 + \frac{3}{3}$ lb.

If, then, we extend and generalise the results of such experiments, we find that, within certain limits, to obtain an orderly series of just observable differences in sensation we must always add the same fraction—one-third of the weight—at each constant step of the series.

Now Fechner assumed that these just perceivable increments of sensation are all of the same value, or are constant; in which case they form an arithmetical series—that is to say, one that is produced by successive additions of the same amount. But the corresponding series of stimuli are not in arithmetical progression, since the successive increments are not of the same amount. The increase is, however, always by the same proportional amount. Each successive stimulus has to be multiplied by a constant factor, $\frac{4}{3}$. The series, therefore, forms an orderly sequence in geometrical progression.

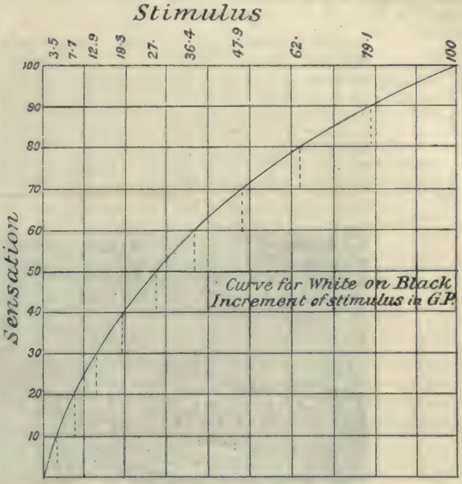
We thus reach what is known as the Weber-Fechner formula, by which the relation of stimulus to sensation is expressed in quantitative terms. It may be thus stated:—To obtain an arithmetical series of sensations a geometrical series of stimuli is required. To give the former, equal increments of sensation are added; to obtain the latter we must multiply the successive stimuli by a constant factor.

It must be admitted, however, that the results of a great number of carefully-conducted observations are by no means in satisfactory accordance with this formula. Hering and his pupils have shown that for very small stimuli, lying near the threshold of sensation, both stimulus and sensation increase very nearly *pari passu* in arithmetical progression. The Weber-Fechner formula cannot, therefore, at present be regarded as more than an approximation to the truth.

In extracting the Weber-Fechner formula from the data afforded by observations on the method of least observable difference, it is necessary to piece together the results observed singly and in succession. But from the nature of the field of vision it is possible to obtain a series of increments of stimulus which shall afford a scale of sensation visible as a whole and at a glance. In the current number of the *Psychological Review* (vol. vii. No. 3, p. 217) I have published in detail the results of an investigation "On the relation of stimulus to sensation in visual impressions," by which I have been led to suggest a modification of the Weber-Fechner formula. Stripped as far as possible of technicalities, the method and results may be here briefly described.

It is well known that if a disc with white and black sectors be rapidly rotated, the effect on the eye is a uniform grey. If the white sectors are proportionally small, occupying, for example, only 5 per cent. of the disc, the effect is that of a very dark grey; if they are relatively large, occupying, say, 90 per cent. of the disc, the effect is that of a very light grey. With such sectors the same proportional amount of white is introduced in all parts of the disc, so as to give in each case the same shade of grey throughout its whole extent. But it is possible to introduce varying proportions of white from centre to circumference, and when this is done the rotating disc no longer presents all over its surface the same uniform shade of grey, but shows varying shades. Let us now endeavour to reduce these varying shades to order. Let us arrange the proportions of white stimulus which we introduce, in such a way as to leave a ring of full black (with no white) at the circumference, and to give a ring of full white (with no black) near the centre, and between these extremes to obtain a perfectly smooth and even gradation of shades of grey from one so dark as to be scarcely distinguishable from black, to one so light as to be scarcely distinguishable from white. We may then, when the disc is rapidly rotating, run our eye from white near the centre, through deepening and deepening grey, to black at the circumference, with nowhere any observable jump in sensation—nowhere, so to speak, a steeper slope of change than elsewhere; as if, in fact, we were passing along a perfectly even inclined plane of sensation from the lowest depth of black to the extreme height of white. If we succeed in this—and it is by no means easy of attainment—we shall have secured an arithmetical series of sensation. From one end to the other we have at successively equal distances constant increments of white sensation, just as in ascending a uniform incline we gain equal increments of height for every yard we progress towards our goal. This even slope of sensation is produced by the juxtaposition of all the least observable differences whose sum gives the full scale. Having obtained this result we are able to ascertain, by careful angular measurements of the proportional areas of white at different parts of our disc, the exact amounts of stimulus which are affecting the eye from these several parts. We may, for example, subdivide the area of the disc lying between the inner white circle and the outer ring of black, by drawing nine concentric circles equidistant from each other, and at these nine distances make angular measurements of the proportional amounts of white to black; and then, by plotting, sweep a curve of stimulus through points representing these measured amounts.

When these amounts are tabulated and dealt with by appropriate mathematical methods, it is found that they are *not* in accordance with the Weber-Fechner formula. Nor does a disc prepared in accordance with this formula give the smooth and evenly-graded incline of an arithmetical series in sensation. For details the reader may be referred to the paper in which the observations and calculations are set forth. The accompanying figure gives the results plotted in a curve on the graphic method. The dotted steps indicate the nine measured increments. The vertical distance of any point on the curve, measured from below, upwards, gives the percentage of sensation. The horizontal distance, measured from left to right, gives the corresponding percentage of white stimulus. The law which results from a discussion of these observations, and of others where red, orange and blue stimuli were used instead of white (each of which gives a different curve on the same principle), may be thus formulated:—*For constant increments of sensation the concomitant increments of stimulus are in geometrical progression.* This differs from the Weber-Fechner formula in assigning the geometrical progression to the successive *increments* of stimulus.



The subjoined table gives the increments and sums of

*White on Black.*

| Stage | Sensation | | Stimulus | | Observed percentage of stimulus |
|---|---|---|---|---|---|
| | Increments | Sums | Increments | Sums | |
| 10 | 10 | 100 | 20·90 | 100 | 100 |
| 9 | 10 | 90 | 17·13 | 79·10 | 79 |
| 8 | 10 | 80 | 14·03 | 61·97 | 62 |
| 7 | 10 | 70 | 11·51 | 47·94 | 48 |
| 6 | 10 | 60 | 9·43 | 36·43 | 35·8 |
| 5 | 10 | 50 | 7·73 | 27 | 27 |
| 4 | 10 | 40 | 6·33 | 19·27 | 19·5 |
| 3 | 10 | 30 | 5·20 | 12·94 | 13 |
| 2 | 10 | 20 | 4·25 | 7·74 | 7·9 |
| 1 | 10 | 10 | 3·49 | 3·49 | 3·5 |
| 0 | 0 | 0 | 0 | 0 | 0 |

stimulus and sensation at ten stages between black and white. A comparison of the last two columns will show the extent of agreement between observation and calculation. The numbers given under the head of stimulus are calculated on the basis of the suggested law, the number 27 per cent. of stimulus, as the concomitant of 50 per cent. of sensation, being taken over from observation as a basis for calculation.

Although I venture to hope that the results of this investigation contribute something towards a solution of the problem, still it will be seen that we have as yet by no means reached the stage at which we can claim that a law expressing the quantitative relation of stimulus to sensation is established beyond question. But from the work of many observers we may at least draw the conclusion that there is some well-defined relation, though its law at present eludes the grasp of our generalisation. And this so far lends support to the doctrine of concomitance.

There has been much discussion as to the true meaning of the relation. Is it primarily a relation between physical stimulus and physiological response, or between physiological response and psychological concomitant? In other words, is the law we seek primarily a physiological or a psychological law? We cannot enter upon the discussion here. Attention may, however, be drawn to two facts:—First, that Prof. Pfeffer claims to have shown that the attractive influence of malic acid on the spermatozoids of ferns is approximately in accordance with the Weber-Fechner formula; and secondly, that Dr. Augustus Waller's researches on the excitation of muscle and nerve indicate some such relation, though not exactly this relation, between stimulus and physiological response. In view of these facts it seems not improbable, therefore, that the relation may prove to be primarily physiological. In which case we may infer that sensation is directly proportional to the molecular disturbance in the nerve-centres concerned.

C. LLOYD MORGAN.

---

## ANEMOMETER TESTS.

THE U.S. *Monthly Weather Review* for February contains an important contribution by Prof. C. F. Marvin on anemometer tests. The paper gives the results of a series of experiments to determine the factor of an anemometer specially designed for use with kites at considerable altitudes in the free air. For that purpose the anemometer has necessarily to be very small and light, and in the present case the cups were only 1·22 inch in diameter, and the length of the arms, from the centre of cup to the spindle, only 1·96 inch. The author describes at length the whirling apparatus used in making the experiments, and which had been previously used in the year 1888, but in an enclosed space, instead of in the free air. He points out that a whirling apparatus is absolutely necessary for testing anemometers, because we have no other means of accurately measuring the speed of the wind to which the instrument is exposed, unless we employ for that purpose some other anemometer, which must itself be first tested. In the author's view, the effect of using the whirler in the open air is to alternately add to and subtract from the artificial wind resulting from the steady motion of the whirler, so that the actual resultant wind affecting the anemometer acquires a *gusty* character which is analogous to the conditions always existing in the free air, and the artificial gusty wind thus secured affords a highly appropriate test-wind for anemometers that are to be used in the open air. The apparatus employed is shown in a plate, which we reproduce.

The arm, on the extreme end of which the anemometer is placed, is 28 feet long, and is made to rotate either by hand-power or by means of the engine used in the kite experiments. By hand-power any speed up to thirty-five miles an hour could be obtained, and by the engine the velocity could be raised to nearly sixty miles an hour. A good break-circuit seconds pendulum clock was employed, in conjunction with an astronomical chronograph, to record results, and the series of comparisons appears to have been carried out with much care and completeness.

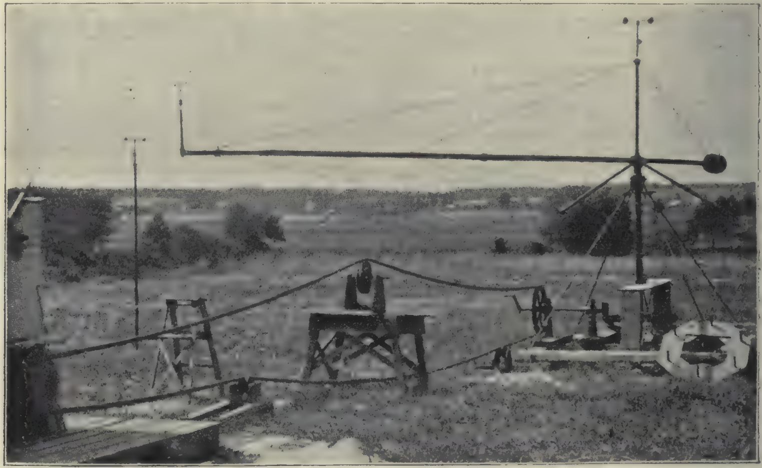


FIG. 1.—Whirling Machine and Driving Belt for Anemometer Tests.

The experiments included a redetermination of the constants for a "standard aluminium cup anemometer," in which the cups were 4·07 inches in diameter, and the arms 6·65 inches in length. This instrument had been used in the investigations of 1888, and the values now obtained gave a slightly lower rate of speed of the cups in a given wind than had been formerly deduced. But as the differences did not exceed 2 per cent., it is fair to conclude that, upon the whole, the agreement was satisfactory.

The author also points out that another result of the experiments is to confirm a conclusion arrived at in 1888, viz. that an anemometer with large cups, as compared with the length of the arms, runs at a speed bearing a more nearly constant ratio to that of the wind than an anemometer with relatively larger arms. In the case of the small kite anemometer now investigated, the factor is practically constant for velocities from ten to fifty miles an hour, the extreme variation being only about 1·5 per cent.

## THE GREAT ALPINE TUNNELS.[1]

THE subject for this evening's discourse is that of the three great tunnels through the Alps—viz. the Mont Cenis, the St. Gothard, and that which is now in course of construction, the Simplon.

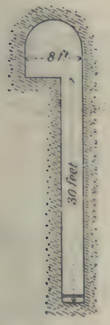
But before dealing with the details of these particular works, it will be desirable to consider what tunnelling is, and also some of the more remarkable instances of it in bygone days.

One great drawback in connection with the subject—so far as a discourse is concerned—is its unsuitability for the photographic art. Unlike a battleship, or a splendid bridge, or a grand block of buildings which can be made into fine views and pictures, the work of the mole is hardly adapted to the sensitive plate. I therefore propose to make use of the "language of the pencil," and to make a few rough sketches on the blackboard: by these means I trust I may be able to explain some of the difficulties which have to be encountered, and also show how a tunnel is constructed. The child's definition of drawing, "first you think, and then you draw a line round your think," will come to our aid.

The art of tunnelling dates back to very remote ages, and there are records of such works which were constructed 500 to 600 years before the Christian era.

An interesting account is given by one of your most distinguished members, in an article in the "Encyclopædia Britannica," of the tunnel under the river Euphrates at Babylon. This city, similar in some respects to London, lay half on one side and half on the other side of the river. High walls, penetrated by occasional gates, surrounded the city, and lined each of the banks of the river. These gates (of which a pair of the great hinges can be seen in the British Museum) were closed at night and during war; and a tunnel was constructed below the bed of the river by means of what is technically known as the "cut-and-cover" system. In those days the Greathead shield was unknown, and consequently the river had to be diverted, so that the excavation could be made in the dry bed and cut open to daylight, the arch being built, the ground restored, and the river allowed to resume its former course. The tunnel is said to have been 15 feet in width, and 12 feet in height, built of brick.

*Fig. 1.*



CROSS SECTION of the AQUEDUCT of EUPALINOS.

*In the Island of SAMOS.*

Herodotus gives an account of the diversion of the river into a great excavation or artificial lake forty miles square, and states that the besieging enemy, so soon as the water was drawn off, entered into the city by the river bed. It is believed that this same excavation was made use of for the construction of the tunnel. It is, however, desirable to state that doubts have been thrown on the subject, and it is possible that it may have to be relegated to mythology.

The next instance of a tunnel is that referred to by Herodotus in the Island of Samos ("Herodotus," iii. p. 60) (see Fig. 1), and it is satisfactory to know that although very considerable doubts were expressed as to the accuracy of his statements, recent investigations prove that he was exactly correct. The description given by him, when expressed in English words and figures, is as follows: "They have a mountain which is 910 feet in height; entirely through this they have made a passage, the length of which is 1416 yards. It is, moreover, 8 feet high, and as many wide. By the side of this there is also an artificial canal, which in like manner goes quite through the mountain; and though only 3 feet in breadth, is 30 feet deep. This, by the means of pipes, conveys to the city the waters of a copious spring."

The commentators on this passage say that Herodotus must have made a mistake, but the Rev. H. F. Tozer, in his book "The Islands of the Ægean," p. 167, gives the results of a personal visit.

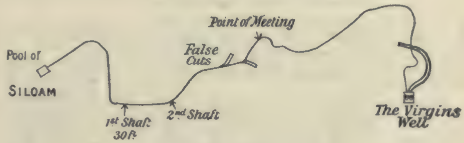
He says the tunnel is 7 to 8 feet in width; that two-thirds of its width are occupied by a footpath, the other third being a watercourse, 30 feet deep at one end. He and other writers consider that insufficient allowance was made for the fall of the water, and that the water channel had to be deepened. To describe it in more modern language, the resident engineer evidently made a mistake in his levels, necessitating a much deeper excavation than was at first anticipated.

Another, and if possible a more interesting, instance of tunnelling is that described in the *Proceedings* of the Palestine Exploration Society, in connection with the Pool of Siloam, made by Hezekiah, B.C. 710, 2 Kings xx. 20 ("Palestine Exploration," 1882, p. 178). See Fig. 2.

About 710 B.C. a tunnel was driven from the spring to the well—by actual tunnelling—the work being commenced at the two ends, and by shafts, and the workmen met in the middle. The tunnel was only 2 feet in width and 3 feet in height, except at the probable point of meeting, where the height is 4 feet 6 inches. The length is 1708 feet, and there is a fall of 1 foot in this distance. About the middle of its course there are apparently two false cuts, as if a wrong direction had been taken: but possibly these were intentional, and provided passing places for the workmen and material.

*Fig. 2.*

*Plan of Tunnel from Spring to Pool of Siloam.*



(Not to scale.)

On the soffit of the tunnel is carved an inscription, of which the following is a translation:—

"Behold the excavation. Now this had been the history of the excavation. While the workmen were still lifting up the pick, each towards his neighbour, and while 3 cubits (4 feet 6 inches) still remained to cut through, each heard the voice of the other, who called to his neighbour, since there was an excess of rock on the right hand and on the left. And on the day of the excavation the workmen struck each to meet his neighbour pick against pick, and there flowed the waters from the spring to the pool for a thousand two hundred cubits (1820 feet), and a hundred cubits (151 feet) was the height of the rock over the head of the workmen."

A Roman engineer gives an account of a tunnel which was being driven under his directions for an aqueduct. And as he was only able to visit the work occasionally, he describes how on one of his visits he found the two headings had missed each other, and he says that had his visit been deferred much longer there would have been two tunnels.

The accurate meeting of the headings or driftways of a tunnel can only be attained by the exercise of great care, both as regards direction as well as level.

We need not go very far to find instances of such an error as inaccurate meeting, but there is one well-known case on an important main line in the Midland Counties where the engineers failed to meet, and to this day reverse curves exist in the tunnel to overcome the difficulty.

To attain this accurate meeting fine wires are hung down the shafts of a tunnel, with heavy plumb-bobs suspended from them in buckets of water, or of tar, to bring their oscillations to rest; the accurate direction being given by means of a theodolite or transit instrument on the surface.

---

[1] A discourse delivered at the Royal Institution on Friday, May 25, by Francis Fox, Mem.Inst.C.E.

The wires are capable of side movement by means of a delicate instrument, and are gradually brought exactly into the same vertical plane: hence, if they are correct at "bank," or surface, they must also be correct below ground. The engineers below have to drive the galleries or headings so that only *one* wire is visible from their instrument: so long as one wire exactly eclipses the other wire, the gallery is being driven in the right direction.

As regards accuracy in levels, this is done by ordinary levelling; but it will be seen at once how much depends on care being devoted to both these operations.

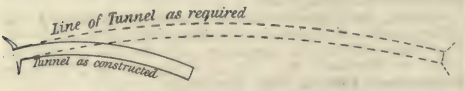


*Fig. 3.* PLAN.

Assume two shafts, 1000 yards apart, between which a gallery has to be driven; and, allowing a distance of 10 feet between the wires, which are $\frac{1}{40}$th inch in diameter, an error of the diameter of the wire at the shaft will cause a mistake of nearly 4 inches at the point of meeting, or of $7\frac{1}{2}$ inches if a similar error occurs at the other shaft in the opposite direction. The trickling of water down the wires increases their diameter so appreciably, and therefore conduces to further inaccuracy, that it is found necessary to fix a small shield or umbrella on the wire to deflect the water.

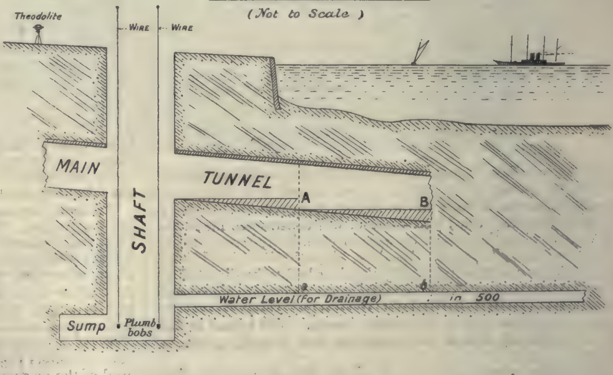
Some years ago, a tunnel which had been commenced, but not finished, had to be completed. The first thing to be done by the engineers was to make an accurate survey of the then condition of the work—this rough sketch (see Fig. 3) indicates what was discovered. The explanation given by the former "ganger" was, that he found the rock too hard, and he thought that by bearing round somewhat to the right, he might get into more easily excavated material!

When the wires are hung down the shaft it is sometimes almost impossible to prove that they are not touching, and consequently being deflected from the true vertical line by some rope or pipe, staging or timber in the shaft. To overcome this, an electrical current was passed down the wire—a galvanometer being in circuit. If the wire proved absolutely silent, and no deflection was obtained in the galvanometer, the conclusion could be safely drawn that the wire was hanging freely and truly.

In driving the necessary adit or heading for drainage purposes beneath a sub-aqueous tunnel, a rising gradient from the shaft bottom of 1 in 500 is allowed, to enable the water at the "face" to flow away from the workmen to the pumps in the "sump" or shaft bottom (see Fig. 4).

*Fig. 4.* *Diagrammatic Section to illustrate method of constructing Tunnel below River Bed.*

(*Not to Scale*)



When the heading is driven sufficiently forward to justify the commencement of the main tunnel, a fresh difficulty presents itself. This main tunnel has to be driven down hill, and consequently the water collects at the working face A; the bottom cannot therefore be removed until a bore-hole is put down from A to *a*. When this is done the remaining excavation can be taken out, and a further length of tunnel driven to B. A bore-hole is now sunk from B to *b*, whilst that from A to *a* can be plugged up: and thus the tunnel is gradually advanced.

By the adoption of the Greathead shield much of this difficulty can be avoided; but one sub-aqueous tunnel through water-bearing strata, at considerable depth, is sufficient for a lifetime.

As an illustration of the danger to which men are exposed in such work, it is stated, with much regret, that in a certain tunnel, notwithstanding every precaution being taken, all the men engaged in driving the drainage heading by means of a tunnelling machine have died; and in the case of the first Vyrnwy tunnel crossing of the River Mersey—driving by Greathead shield under pressure—the mortality was great.

Having explained in very general terms some of the difficulties of tunnel construction, we will proceed to the case of the great tunnels through the Alps, and for the purpose of rendering the subject more easily intelligible, the following particulars may be given:—

| | St. Gothard | Mont Cenis | Arlberg | Simplon |
|---|---|---|---|---|
| Length of tunnel in miles ... ... | 9·3 | 7·98 | 6·36 | 12·26 |
| North or east portal above sea-level, feet | 3639 | 3766 | 4296 | 2254 |
| South or west portal above sea-level, feet | 3757 | 4164 | 3998 | 2080 |
| Highest level ... ... | 3788 | 4248 | 4300 | 2314 |
| Maximum grade in tunnel per 1000 ... | 5·82 | 30 | 15 | 7 |
| Maximum height of mountain above tunnel, feet... ... ... | 5598 | 5428 | 2362 | 7005 |
| Possible maximum temperature of rock, deg. Fahr. ... ... | 85° | 85° | 65° | 104° |

## MONT CENIS TUNNEL.

The Mont Cenis, or as it is more accurately called, the Frejus Tunnel, is nearly eight miles in length. It is for a double line of way—width being 26 feet, and height above rails 20 feet 6 inches.

In consequence of the gradients in the Mont Cenis ascending from both ends, the smoke cannot get away, and it remains in a dull, heavy cloud in the tunnel. It is worse during cold and rainy weather, and particularly during the winter, when the air is sometimes so deficient in oxygen that the plate-layers cannot work.

Trains coming from France with an ascending gradient of 1 in 40 against them for a length of 7 kilometres, when followed by a current of air in the same direction, produce a disastrous state of things. In this, as in all other steep tunnels, engines having a heavy load behind them go through with their regulators full open, ejecting great volumes of smoke and steam which travel concurrently with the train, and the inconvenience and discomfort produced are very great.

At each kilometre in the tunnel, a refuge or "grande chambre" is provided for the men, and this is supplied with compressed air, fresh water, a telephone in each direction out, a medicine chest, barometer and thermometer.

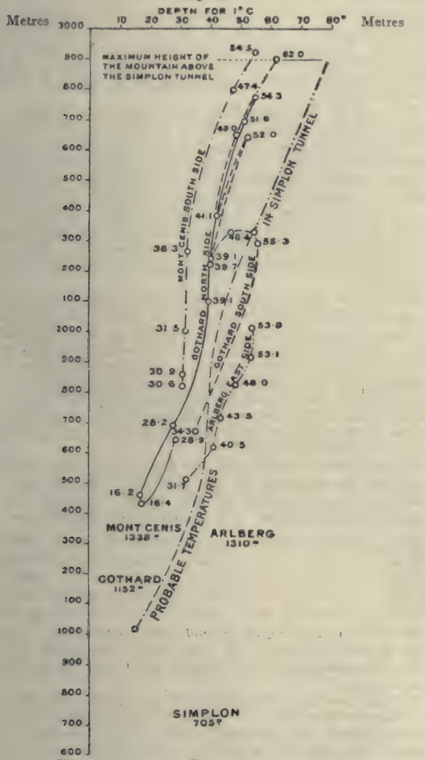
The cost of the tunnel was about 3,000,000*l.*, or 220*l.* per yard, and occupied ten years in construction.

The temperature in the middle of the tunnel remains nearly constant, summer and winter, and is about 19° to 20° C. = 66° to 68° Fahr.

The altitude of the tunnel is 4248 feet above sea-level, and the height of the mountain above the tunnel is 5428 feet: the temperature of the rock is greatly influenced by this latter fact.

The question of the temperature of the rocks passed through in the construction of a tunnel is one of great interest, as it depends upon several conditions: (1) the character of the rock; (2) the inclination of the beds—those which attain a vertical or nearly vertical position being less able to confine the heat than those which are more or less horizontal; (3) the height of the mountain above the tunnel, or in other words, the thickness of the blanket.

*Fig. 5.*



CURVES SHOWING DEPTHS CORRESPONDING TO AN INCREASE IN TEMPERATURE OF 1° C. FOR THE MONT CENIS, GOTHARD AND ARLBERG TUNNELS.

(With curve of probable temperature for the Simplon Tunnel.)

A diagram is shown (Fig. 5), giving the temperature actually encountered in the St. Gothard and Arlberg Tunnels, and from these, aided by the carefully prepared geological section along the centre line of the Simplon Tunnel, an approximate line is given of the temperatures which are expected.

The possibility of cooling the rocks and the air of the tunnel will be dealt with later on, but there is in addition a permanent lowering of the temperature after the tunnel is complete, particulars of which will be given under the description of the St. Gothard.

For each 144 feet of superincumbent rock or earth the increase is found to be 1° Fahr.

### THE ST. GOTHARD TUNNEL.

This, which is at present the longest railway tunnel in the world, is 9·3 miles in length, and constitutes the summit of the "Gothard bahn," that is, the railway which runs from Lucerne to Chiasso near the Italian frontier.

The altitude of the tunnel at its north portal is 3639 feet, and at its south portal 3757 feet above the sea. A gallery of direction was driven throughout, and the gradient of the rails is only such as to provide for efficient drainage, viz. 5·82 per thousand, or about 1 in 172.

The following table may be of interest, giving the result of investigations as to the cooling of the rocks.

TEMPERATURE OF THE ROCK IN THE ST. GOTHARD TUNNEL.

| Date. | 7·3 kilo. from the North Portal. | | | 7·05 kilo. from the South Portal. | | |
|---|---|---|---|---|---|---|
| | Temperature. | Lowering. | | Temperature. | Lowering. | |
| | | Successive. | Total. | | Successive. | Total. |
| | ° | ° | ° | ° | ° | ° |
| April and May 1880, the year when the tunnel was pierced | 30·46 | ... | ... | 30·53 | ... | ... |
| June 1882 ... ... | 23·73 | 6·73 | ... | 23·39 | 7·14 | ... |
| July 1883 ... ... | 22·20 | 1·53 | 8·26 | 23·1 | 0·29 | 7·43 |

Above are Centigrade.

Although the works were carried on with energy, and with all the best appliances then known, the time occupied was ten years; but the most serious feature of the work was the heavy mortality amongst the men: no less than 600 deaths occurred, including those of both the engineer and contractor.

From the experience then gained, great improvements have been introduced into the works of the Simplon, as will be described later on; but the heavy loss of life in the St. Gothard was due to insufficient ventilation; the high temperature; the exposure of the men to the Alpine climate after emerging from the tunnel; the want of care as to the changing of the men's wet mining clothes; and the poor character of the food with which the men supplied themselves. All this has been greatly ameliorated, and even in English tunnels certain improvements have been introduced, which were brought from Switzerland.

The traffic through the tunnel has so largely increased that the question of ventilation became of pressing importance, and the system of Signor Saccardo, the well-known Government inspector of railways and engineer of Bologna, has been installed, which is an ingenious application of the injector system. One of the first introductions of this method was in the case of the Pracchia Tunnel, on the main line between Florence and Bologna, through the Apennines. This is a railway of single line, and was built many years ago by the late Mr. Brassey. There are 52 tunnels in all, but those on the eastern side are of comparatively little importance. On the western slope the gradient nearly throughout is 25 per thousand (or 1 in 40), and it is here the greatest difficulty exists. There are several tunnels whose lengths approximate to 1000, 2000 and 3000 yards, and the traffic is both heavy and frequent, the locomotives very powerful, with eight wheels coupled.

Under any conditions of wind the state of the longest tunnel is bad, but when the wind is blowing in at the lower end at the same time that a heavy goods or passenger train is ascending the gradient, a state of affairs is produced which is almost insupportable, and one might as conveniently travel in a furnace flue.

A heavy train of dining and sleeping carriages, with two engines, conveying one of the crowned heads of Europe and suite, arrived at the exit of Pracchia Tunnel with both enginemen and both firemen insensible; and in other cases passengers have been seriously affected.

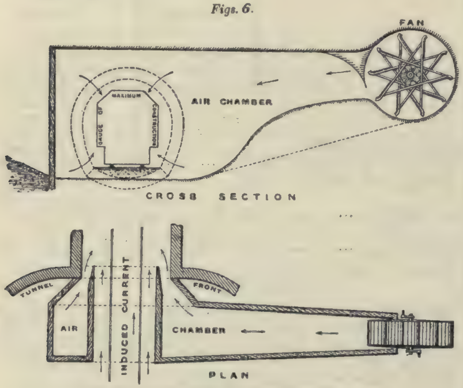
Owing to the height of the mountain no shafts are available; but Signor Saccardo places a ventilating fan near the mouth of the tunnel, and blows air into it through the annular space which exists between the arch of the tunnel and the gauge of maximum construction (Fig. 6). The results are remarkable; the volumes of air thrown into the tunnel per minute being as follows:—

| | cub. ft. |
|---|---|
| Direct from the fan ... ... ... ... | 161,860 |
| Induced draught through open tunnel mouth | 48,140 |
| Total ... ... ... | 210,000 |

Or 100 cubic metres per second.

The temperature of the tunnel air before the fan was started was 107° F., with 97 per cent. of moisture, whereas, after the fan had been running a few minutes the temperature was 81° F., or a lowering of 26° F., and the tunnel was cool and free from smoke and vapour.

*Figs. 6.*



The Saccardo System of Ventilating Tunnels.

One can travel through with both windows open and feel no inconvenience, the only remark of the brakesman riding on the top of the waggons and carriages being that he finds it almost too cold.

This application is without doubt the solution of the difficult problem of tunnel ventilation under high mountains, and elsewhere where shafts are not available, and where electric traction is not applicable.

This system has within the last twelve months been brought into operation on the St. Gothard, with the most satisfactory results. Careful experiments are being made, but there is no doubt that the problem has been solved.

In addition to these tunnels, the Saccardo system has been applied to the Giovi Tunnel near Genoa—3300 metres in length—and is being installed on the Giovi Tunnel on the Genoa-Ronco Railway, 8303 metres in length, besides on some seven other tunnels in Italy; and plans are being prepared for the Mont Cenis.

### The Simplon Tunnel.

This tunnel is now in rapid course of construction, the total length of gallery driven up to the end of April being as follows:—

| | yards |
|---|---|
| On the north or Brigue side of the Alps ... | 3228 |
| On the south or Iselle ... ... ... ... | 2350 |

Or over three miles in little more than eighteen months, including the necessarily slow progress at the commencement.

The total distance between the two portals will be 21,564 yards, or 12·26 miles. A gallery of direction has been driven at both ends until the actual tunnels are reached, so as to form a directly straight line for the accurate alignment of the work from end to end.

This great undertaking will consist of two single-line tunnels running parallel one to the other, at a distance apart from centre to centre of 55 feet 9 inches; and one of the chief features is the much lower altitude of the rails above sea-level than any of the other Alpine tunnels. This altitude is at its highest point 2314 feet, being 1474 feet lower level than that of the St. Gothard, 1934 feet lower than that of the Mont Cenis, and 1986 feet than that of the Arlberg. This is a matter of great importance in the question of haulage of all the traffic.

The tunnel enters the mountain at the present level of the railway at Brigue, so that no costly approaches are requisite on this side.

Admirable arrangements have been made for the welfare of the men, to avoid the heavy death-rate which occurred on the St. Gothard, and it may be interesting to state what some of these are. For every cubic foot of air sent into the latter tunnel, fifty times as much will be delivered into the Simplon. Special arrangements are made for cooling the air by means of fine jets of water and spray.

The men on emerging from their work, wet through and fatigued, are not allowed to go from the warm headings into the cold Alpine air outside, but pass into a large building which is suitably warmed, and where they change their mining clothes and are provided with hot and cold douche baths. They put on warm dry clothes, and can obtain excellent food at a moderate cost before returning to their homes. Their wet and dirty mining clothes are taken charge of by appointed custodians, who dry and clean them ready for the morrow's work. These and other precautions are expected to reduce the death-rate to a very great extent.

With a view to the rapid advancement of the work, the late M. Brandt, whose death is greatly to be deplored, devised after his long experience on the St. Gothard his now well-known drill. As details of this have been published, and as they would be too technical for this evening's discourse, it will only be necessary to refer to them briefly. This drill is non-percussive, nor is it armed with diamond. It is a rotatory drill 3 inches in diameter with a pressure on the cutting points of 10 tons moving at slow speed, but capable of being acclerated at pleasure, and of being rapidly withdrawn.

The progress of each of the two faces during the month of April last has averaged 17 feet 3½ inches per day, and is a remarkable corroboration of the speed estimated by the engineers four years ago. The estimate was as follows:—

| | | | | | | |
|---|---|---|---|---|---|---|
| 1st year, | the daily progress | at each | face | would be | ... | 8·85 feet |
| 2nd ,, | ,, | ,, | ,, | ,, | ... | 17·22 ,, |
| 3rd ,, | ,, | ,, | ,, | ,, | ... | 19·18 ,, |
| 4th ,, | ,, | ,, | ,, | ,, | ... | 21·32 ,, |
| 5th ,, | ,, | ,, | ,, | ,, | ... | 31·16 ,, |

The work is now in its second year, so that the estimated speed is being exceeded. In other words, the tunnel is being driven through granite at a higher speed than is attained in London clay.

It was at one time intended to sink a 20-inch bore-hole from the village of Berisal to the tunnel, a depth of some 2400 feet, for the purpose of delivering water at high-pressure for the works. This may still be done, but the meandering of the tool might result in the awkward dilemma of having to search for it, in solid rock, below ground.

The probable cost of the work now in hand will be about 2,000,000*l.*, and the time occupied in completing the tunnel ready for traffic is estimated to be 5½ years, a penalty or a bonus, as the case may be, for delay or acceleration being fixed at 200*l.* a day.

---

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

Oxford.—The following is the text of the speech with which Prof. J. Mark Baldwin, professor of psychology in Princeton University, was presented for the degree of D.Sc. *honoris causa.* This is the first time the degree has been conferred in Oxford, it having been created only quite recently. The speech was written by Mr. A. C. Clark, of Queen's College, and Prof. Baldwin was presented by Prof. E. B. Elliot, F.R.S., in the absence of Prof. Love, F.R.S., who would in the ordinary course have officiated, being the occupant of the oldest scientific chair in the University :

Adest Jacobus Marcus Baldwin, Academiae de Princeton Graduatus, vir Psychologiae peritissimus. Cujus laudes ut brevissime complectar, primo Psychologiae Professor in Academia de Toronto creatus Psychologiae Experimentalis laboratorium, quod solum adhuc in Academiis Britannicis exstat, instituit, mox ad suam almam matrem reversus in Academia de Princeton Psychologiae Professor factus est. Libri etiam luculentissimi auctor est de ortu et incremento intellegentiae cum in infantibus tum in genere hominum universo, quem summa laude a viris doctis ubique ornatum Academia Havniensis numismate aureo donavit : idem ephemeridis praestantissimae apud Americanos res psychologicas tractantis diu editor, nunc grande Philosophiae et Psychologiae Abecedarium sub prelo nostro excudendum curat. Quo in labore doctissimi cujusque in hoc genere scriptoris opera utitur cum in America tum in Europa, quo in numero Praelector noster Wildianus dux est et fere signifer. Valde, nisi fallor, Academiae nostrae auram redolebit hoc volumen tot Oxoniensium sive sub nostro caelo, sive sub externo degentium, opera diligentia doctrina exquisita ornatum.

Quod vero primus Scientiae Doctor in Academia nostra creatus tantam in Psychologia laudem adeptus sit, felicissime profecto accidit, cum adhuc frigere apud nos hujus doctrinae studium externis videatur. Utinam hunc talem virum plurimi ejusdem laureae avidi longo ordine secuturi sint.

Illam vero insignem benevolentiam praetermittere non possum Academiae de Princeton, quae plurimos, qui in hac nostra Academia laude summa floreant ac floruerint, gradibus honoris causa conferendis libentissime auxerit. Cujus liberalitatis non immemor maximo cum gaudio ego hunc virum doctissimum, Academiae suae vivum exemplar, vobis ornandum trado.

The speech delivered by Prof. Love on the occasion of the presentation of Prof. C. F. Chandler, of Columbia College, for the degree of D.Sc. *honoris causa*, was as follows :—

Adest Carolus Fredericus Chandler, chemiæ professor apud Americanos, cuius fama extra fines patriæ suæ iam dudum pervagata est. Hic apud suos litteris humanioribus primo imbutus, dein chemiæ deditus doctrinæ amplioris appetens ad Germanorum fontes accessit. Ibi doctissimi cuiusque viri, cum in Berolinensi Academia, tum in Gottingensi discipulus, Philosophiæ Doctor et Magister Artium apud Gottingenses creatus est. Ex hoc curriculo ad solum suum reversus in Academia de Schenectady primo vicarius erat Professoris optimi, Caroli Joy, dein hoc summo viro ad Academiam de Columbia avocato, ipse Professor factus septem annos de omni chemiæ genere, de agris lætificandis, de metallorum ratione, de geologia magnum discipulorum gregem praeclare docebat. Ita laudem insignem adeptus ipse Columbiam arcessitus, ubi scholæ metallorum novo exemplo instituendæ imprimis auctor erat, tres et triginta annos in omni rerum administratione florebat. Per hoc grande mortalis ævi spatium omne genus chemiæ felicissime tractavit : idem rude iam donatus a laboribus officiosis nondum recessit sed iuniorum studia adhuc informat. Neque hoc loco silendum arbitror quod huius precibus commoti fratres Havermeyeri, Novi Eboraci cives ornatissimi, aulam pulcherrimam, chemiæ sedem, ædificaverunt : Musæi etiam rebus omnibus, quæ ad chemiam pertinent, refertissimi ipse auctor est et conditor. Sex et viginti abhinc annos magna chemicorum frequentia ad Doctoris Priestly sepulchrum confluente, ut chemiæ inventorem rite salutarent et post centesimum iam annum scientiæ suæ natalem diem celebrarent, ipse conventus Præses erat : Societas autem chemicorum Americanorum, quæ ex illo coetu orta est, hunc bis Præsidem sæpe vice-Præsidem et curatorem habuit. Sodalicii etiam chemicorum, qui Novi Eboraci degunt, Præses est : hortorum etiam publicorum peritissimus Curator. Idem civitatis suæ personam gerens maximo medicorum conventui Havniæ interfuit, qui ab omni terrarum orbe missi de valetudine civium conservanda quærerent.

Dies mehercule me deficeret si doctissimi viri tot labores enumerare conarer. Illum consulunt populares sui de porcorum fibra unaquaque in quæstum convertenda, de silvis rei navalis causa conservandis, de veneno si quod in vino vel in cervisia delitescat detrahendo, de argentariorum chartulis imperviis aquæ et madori reddendis, de oleo e vivis fontibus scaturiente purgando, de plateis igneo vapore noctu illuminandis, de mercibus linteis candore eximio nivem superantibus, de omni re quæ ad utilitates, oblectamenta, lucrum denique civium pertinet.

Ut omittam honores quos Academia Gottingensis iuveni dedit, Doctor Medicinæ ab Academia Novi Eboraci, Litterarum etiam Doctor ab Academia sua Columbiensi factus est : neque solum domi clarus est, sed ubicunque terrarum viri docti, chemiæ dediti, inveniuntur, hunc sodaliciis et societatibus suis libentissime adsciverunt. Restat ut Academia nostra hoc summo viro in gremium suum accepto suas laudes augeat.

---

At a meeting of the Council of the Birmingham University, held on Tuesday, the following letter, received from Lord Calthorpe by Mr. Chamberlain, was read :—"Dear Mr. Chamberlain,—My son and myself beg to offer to the University of Birmingham about twenty-five acres of land on the Bournebrook side of the Edgbaston estate as a site for the new scientific department of teaching and research which it is proposed to establish. There will of necessity be certain conditions, but these will occasion no difficulty.—Yours very truly, Calthorpe."—It was proposed by the Vice-Chancellor, seconded by Sir James Smith, and unanimously resolved :—"That this Council desires to express to Lord Calthorpe and to the Hon. Walter Calthorpe its high appreciation of their generosity in offering to present twenty-five acres of land to the University of Birmingham as a site for the new scientific department. In gratefully accepting the offer, the Council recognises, not only the value of the gift, but the suitability of the site, which enables it to establish the new department in closer proximity to the centre of the city than would have been possible under any other circumstances."

The Reports and Prospectuses of Technical Schools, which come under our notice from time to time, show unmistakably that increased provision is being made for practical work in science, and that teachers who have had the advantage of instruction in well-equipped laboratories are in charge of the work. The Municipal Science, Art, and Technical Schools of Plymouth is a case in point. These schools were erected by public subscription as a memorial of the Queen's Jubilee, and on their completion were handed over by the Jubilee Memorial Committee to the town. In the day school department the work is that of the Advanced Section of a "School of Science," that is to say, of a secondary school giving instruction in mathematics, mechanics, physical science, English subjects, French and drawing. There is a laboratory for practice in both chemistry and physics, and for manual instruction in woodwork. Both day and evening classes are held in many science subjects, and pupils whose elementary education is completed may take a two years' course of training in such subjects as will best fit them to become chemists, architects, civil, mechanical, or electrical engineers, or to engage in industrial work of any kind. The increase of institutions of this kind will be the salvation of our national welfare.

From the Northampton Institute, one of the youngest of the London Polytechnics, we have received a prospectus of courses in mechanical engineering, electrical engineering, and horological engineering which have just been introduced. The syllabuses of the courses are admirable, and, with the notes upon the objects and character of the work, they indicate that Dr. R. M. Walmsley, the principal, believes in the value of scientific instruction. Students who desire to take up these engineering courses must first show that they are capable of benefiting from it by passing an entrance examination. English and elementary mathematics are obligatory subjects, and we are glad to see that it is not proposed to make the latter a test of ability to perform mathematical gymnastics. The following extract from the prospectus is worth quoting :—"In 'Elementary Mathematics' the examination will aim at ascertaining the candidate's familiarity with simple arithmetical, algebraical and geometrical methods and their application so the solution of ordinary common-sense problems. In arithmetic this will include the use of decimals and abbreviated methods of calculation, with the usual problems of mensuration, including the volumes and surfaces of cylinders, spheres and right cones. In algebra the usual course as far as simple simultaneous equations will be included, but the more academic parts of the subject will not be required. The geometry will include the subjects treated in the first two books of Euclid, with some exercises in the accurate drawing of geometrical figures." The Institute has numerous laboratories and workshops for practical work in mechanics, engineering, metal and woodwork, electrical engineering, physics, electro-chemistry, metallurgy, and instrument making. The attention given to horological theory and mechanism, and horological technology, is a noteworthy characteristic. The courses of work in this as well as the other subjects show that sound instruction in the principles and practice of the chief branches of engineering can be obtained at the Institute.

## SCIENTIFIC SERIALS.

*American Journal of Science*, July.—Energy of kathode rays, by W. G. Cady. This is a translation of a paper already published in the *Annalen der Physik*.—Volcanic rocks from Temisconata Lake, Quebec, by H. E. Gregory. The volcanic rocks consist of fine tuff and coarse amygdaloidal conglomerate or breccia. They are interbedded with Niagara sediments, and this helps to determine the time when widespread volcanic activity gave rise to the numerous small areas of tuffs and lavas in the Maine-Quebec region.—Interpretation of mineral analyses, and a criticism of recent articles on the constitution of tourmaline, by S. L. Penfield. It is safe to assume that the close approximation of atomic ratio to whole numbers constitutes the strongest argument that can be advanced in support of the excellence of an analysis and to correctness of the derived formula. The author criticises the formulæ proposed by Clarke and Tschermak, and maintains that it is definitely proved that the empirical formula of the tourmaline acid is $H_{20}B_2Si_4O_{21}$.—Carboniferous boulders from India, by B. K. Emerson. The author describes and illustrates some striated carboniferous boulders which remove the doubt as to the former existence of a carboniferous glacial period.—The statement of rock analyses, by H. S. Washington. The author proposes a regular system of stating the results of the chemical analysis of rocks. The oxides are to be enumerated in the following succession: $SiO_2$, $Al_2O_3$, $Fe_2O$, FeO, MgO, CaO, $Na_2O$, $K_2O$, $H_2O$, $CO_2$, and then the rarer oxides, also in definite succession. This will enable the geologist to classify the rocks in a purely chemical system and to pick them out at a glance. They can be advantageously entered upon a card catalogue.—A string alternator, by K. Honda and S. Shimizu. The authors describe a modification of Pupin's string interrupter by means of which a continuous battery current can be converted into an alternating current the frequency of which can be readily varied from 30 to 1000 per second.—Action of light on magnetism, by J. H. Hart. The author failed to obtain the demagnetisation of iron by light acting magnetically like an alternating current, until he adopted the expedient of depositing very fine iron films on glass. He then noticed a small but distinct difference in the magnetic state of the iron according to the plane of polarisation of the incident light.

*Bollettino della Società Sismologica Italiana*, vol. vi. 1900–1901, N. 1.—Rules and list of fellows (forty-three national and thirteen foreign).—Vesuvian notices (year 1899), by G. Mercalli. A monthly review of the condition of Vesuvius, with sections on the form and state of the crater, the end of the eruptive phase of 1895–1899, the lavic cupola of 1895–1899, the supposed endogenous elevation of the lavic cupola, and the fumaroles of the lavic cupola and fracture.—On the nature of seismic vibrations, by M. P. Rudski (in French). The author contends that superficial, and probably deep-seated, rocks are not isotropic media, and that earthquake waves consist of vibrations which are not entirely longitudinal or entirely transversal.—Notices of earthquakes recorded in Italy (January 1 to March 14, 1896), by A. Cancani, the most important being the Mexican earthquakes of January 14 and 25, the Greek earthquake of January 22, and distant earthquakes on January 6, 22, and March 7.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, May 17.—"The Circulation of the Surface Waters of the North Atlantic Ocean." By H. N. Dickson, B.Sc. Communicated by Sir John Murray, K.C.B., F.R.S.

In this paper an attempt is made to investigate the normal circulation of the surface waters of the Atlantic Ocean north of 40° N. lat., and its changes, by means of a series of synoptic charts showing the distribution of temperature and salinity over the area for each month of the two years 1896 and 1897.

The principal conclusions arrived at with reference to the circulation may be summed up as follows:—

(1) The surface waters along the whole of the eastern seaboard of North America north of (about) lat. 30° N., consisting partly of water brought from the equatorial currents by the Gulf Stream, and partly of water brought down by the Labrador current, are drifted eastward across the Atlantic towards south-western Europe, and banked up against the land outside the continental shelf. This continues all the year round, but it is strongest in summer, when the Atlantic anti-cyclone attains its greatest size and intensity; and the proportion of Gulf Stream water is greatest at that season.

(2) The drifts in the northern part of the Atlantic area are under the control of the cyclones crossing it. The circulation set up accordingly reaches its maximum intensity in winter, and almost dies out in summer. In winter the drifts tend to the south eastward from the mouth of Davis Strait, eastward in mid-Atlantic, and north-eastward in the eastern region. In spring and autumn the movement is more easterly over the whole distance, and a larger quantity of water from the Labrador stream is therefore carried eastward.

(3) The water banked up in the manner described in (1) escapes partly downwards, partly southwards, and partly northwards. It occupies the whole of the eastern basin of the North Atlantic, and to the north it extends westward to Davis Strait, being confined below 300 fathoms depth by the ridges connecting Europe, the Faeroes, Iceland, and Greenland. Above that level it escapes northward by a strong current through the Faeroe-Shetland Channel and between Faeroe and Iceland, and by the two branches of the Irminger stream, one west of Iceland the other west of Greenland.

(As it seems desirable that this northerly current should have a distinctive name, it might be well to call it the European stream, and its branches the Norwegian, Irminger, and Greenland streams respectively.)

The strength and volume of the European stream is liable to considerable variation, according to the form and position of the Atlantic anti-cyclone, which causes the amount of banked up water, and the proportions escaping northward and southward, to vary. It is also modified by the strength and direction of the surface drifts in its course. It is, however, always strongest in summer.

(4) The Norwegian stream is by far the largest branch of the European, and it traverses the Norwegian Sea and enters the Arctic Ocean. The warm water thus sent northward melts enormous quantities of ice, and the fresh water derived from the ice moves southward in autumn, chiefly in a wide surface current, between Iceland and Jan Mayen, which may entirely cover other parts of the Norwegian stream. Part of the surface water also comes southward through the Denmark Strait, but the amount is much smaller, probably chiefly because the melting of the ice is slower, and the channel is longer blocked.

The Greenland branch of the European current also causes melting of ice in Davis Strait, but the warm winds from the American continent and the water received from the land are probably more effective in increasing the volume of the Labrador current.

(5) The water from the melted ice is spread over the surface of the North Atlantic during late autumn and winter by the increasing drift circulation, and it is gradually absorbed by mixing with the underlying water.

(6) The circulation described is liable to extensive irregular variations, corresponding to variations in the atmospheric circulation.

May 31.—"Influence of the Temperature of Liquid Hydrogen on Bacteria." By Allan Macfadyen, M.D., and Sydney Rowland, M.A. Communicated by Lord Lister, P.R.S.

In a previous communication we have shown that the temperature of liquid air has no appreciable effect upon the vitality of micro-organisms, even when they were exposed to this temperature for one week (about − 190° C.). (*Roy. Soc. Proc.*, February 1; *ibid.*, April 5.)

We have now been able to execute preliminary experiments projected in our last paper as to the effect of a temperature as low as that of liquid hydrogen on bacterial life. As the approximate temperature of the air may be taken as 300° absolute, and liquid air as 80° absolute, hydrogen as 21° absolute, the ratio of these temperatures roughly is respectively as 15 : 4 : 1. In other words, then, the temperature of liquid hydrogen is about one-quarter that of liquid air, just as that of liquid air is about one-quarter of that of the average mean temperature. In subjecting bacteria, therefore, to the temperature of liquid hydrogen, we place them under conditions which, in severity of temperature, are as far removed from those of liquid air as are those of liquid air from that of the average summer temperature. By the kindness of Prof. Dewar, the specimens of bacteria were cooled in liquid hydrogen at the Royal Institution. The following organisms were employed: *Bac. acidi lactici*, *B. typhosus*, *B. diphtheriae*, *Proteus vulgaris*, *B. anthracis*, *B. coli communis*, *Staphylococcus pyogenes aureus*, *Spirillum cholerae*, *B. phosphorescens*, *B. pyocyaneus*, a Sarcina and a yeast.

The above organisms in broth culture were sealed in thin glass tubes and introduced directly into liquid hydrogen contained in a vacuum jacketed vessel immersed in liquid air. Under these conditions they were exposed to a temperature of about −252 C. (21° absolute) for ten hours. At the end of the experiment the tubes were opened, and the contents examined microscopically and by culture. The results were entirely negative as regards any alteration in appearance or in vigour of growth of the micro-organisms. It would appear, therefore, that an exposure of ten hours to a temperature of about −252° C. has no appreciable effect on the vitality of micro-organisms.

We hope to extend these observations on the influence of the temperature of liquid hydrogen on vital phenomena, and to make them the subject of a future communication, and to discuss their bearing upon problems of vitality.

June 21.—"On the Viscosity of Gases as affected by Temperature." By Lord Rayleigh, F.R.S.

A former paper[1] describes the apparatus by which I examined the influence of temperature upon the viscosity of argon and other gases. I have recently had the opportunity of testing, in the same way, an interesting sample of gas prepared by Prof. Dewar, being the residue, uncondensed by *liquid hydrogen*, from a large quantity collected at the Bath springs. As was to be expected,[2] it consists mainly of helium, as is evidenced by its spectrum when rendered luminous in a vacuum tube. A line, not visible from another helium tube, approximately in the position of $D_5$ (Neon) is also apparent.[3]

The result of the comparison of viscosities at about 100° C. and at the temperature of the room was to show that the temperature effect was the same as for *hydrogen*.

In the former paper the results were reduced so as to show to what power ($n$) of the absolute temperature the viscosity was proportional.

| | $n$. | | $c$. |
|---|---|---|---|
| Air | 0·754 | ... | 111·3 |
| Oxygen | 0·782 | ... | 128·2 |
| Hydrogen<br>Helium | 0·681 | ... | 72·2 |
| Argon | 0·815 | ... | 150·2 |

Since practically only two points on the temperature curve were examined, the numbers obtained were of course of no avail to determine whether or no any power of the temperature was adequate to represent the complete curve. The question of the dependence of viscosity upon temperature has been studied by Sutherland,[4] on the basis of a theoretical argument which, if not absolutely rigorous, is still entitled to considerable weight. He deduces from a special form of the kinetic theory as the function of temperature to which the viscosity is proportional

$$\frac{\theta^{\frac{1}{2}}}{1 + c/\theta} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (1),$$

$c$ being some constant proper to the particular gas. The simple law $\theta^{\frac{1}{2}}$, appropriate to "hard spheres," here appears as the limiting form when $\theta$ is very great. In this case, the collisions are sensibly uninfluenced by the molecular forces which may act at distances exceeding that of impact. When, on the other hand, the temperature and the molecular velocities are lower, the mutual attraction of molecules which pass near one another increase the number of collisions, much as if the diameter of the spheres was increased. Sutherland finds a very good agreement between his formula (1) and the observations of Holman and others upon various gases.

If the law be assumed, my observations suffice to determine the values of $c$. They are shown in the table, and they agree well with the numbers for air and oxygen calculated by Sutherland from observations of Obermayer.

"Underground Temperature at Oxford in the Year 1899, as determined by Five Platinum Resistance Thermometers." By Arthur A. Rambaut. M.A., D.Sc., Radcliffe Observer. Communicated by E. H. Griffiths, F.R.S.

**Royal Microscopical Society**, June 20.—Mr. Carruthers, F.R.S., President, in the chair.—Mr. G. H. J. Rogers exhibited a modification of the Rousselet compressor, in which two thin indiarubber bands, sunk into grooves, were employed to keep the cover-glass in position, instead of having it cemented, the advantage claimed for this modification being the facility with which a broken cover-glass can be replaced.—Mr. Chas. Baker exhibited an achromatic substage condenser which was a modification of Zeiss's model of the Abbe condenser, the N.A. being 1·0, aplanatic cone 90°, lenses $\frac{7}{10}$-inch diameter, working distance $\frac{4}{10}$-inch. With the front lens removed the condenser is suitable for use with low-power objectives.—A short paper by Mr. E. B. Stringer, on a new projection eye-piece and an improved polarising eye-piece, was taken as read.—A paper by Miss Loraine Smith, on some new microscopic fungi, was also taken as read, the President giving a short *résumé* of it and expressing his opinion that the paper would be an important addition to our knowledge of microscopic fungi. Mr. Bennett said there was one special point with regards to parasitic fungi which might prove to be of considerable practical importance—he referred to the cultivation of fungus parasites on certain insects It had been proposed to do this on the Continent and in Australia and America, with a view of getting rid of insect pests—locusts and others; and if efforts in this direction were successful they might be the means of producing very beneficial and economic results.—The President then read a paper, and gave a lantern demonstration, on the structure of some palæozoic plants. He said the intelligent study of palæozoic plants was not yet a century old, for although their presence had long been noticed, they appear to have been regarded simply as freaks of nature. The importance of fossils was first recognised by Wm. Smith, who observed that strata could be identified by the organised fossils found in them. He published this important fact in 1816, and thus laid the basis of stratigraphical geology. The majority of fossil plants are found in the shales, and although the tissues had been converted into carbon, the form and venation of the leaves and occasionally the aspect of the fruits had been preserved. The most important information, however, had been obtained from specimens in which the tissues had been replaced by minerals dissolved in the strata enclosing them. He had arranged for the lantern sections of plants from the carboniferous system, but before exhibiting them he wished to point out to what group of plants they belonged. The cellular plants, with few exceptions, had been lost. Sir Wm. Dawson found specimens of a remarkable stem in the lower Devonian rocks of Canada, to which he gave the name of *Protaxites*. From a microscopic study of specimens he, the President, was led to publish a paper in the Society's *Journal* in 1872, in which he demonstrated that the stem was that of a cellular plant belonging to the Algæ, a view which was ultimately accepted by Sir Wm. Dawson. Fungal remains had been detected by Alder, and also by himself. The plants which had been certainly determined were vascular plants belonging to the Equisetaceæ, Filices, and Selaginellaceæ, among Cryptogams, and to the Coniferæ, groups which existed in the present flora of the globe, and were represented in the indigenous flora of Britain. The President proceeded to describe the principal characteristics of the fossil and existing forms of the four orders of plants referred to. In illustration of his remarks a number of preparations were shown on the screen.—Mr. Bennett wished to say a few words to elicit an opinion on a matter of great interest.

---

[1] *Roy. Soc. Proc.*, vol. lxvi. (1900), p. 68.

[2] *Roy. Soc. Proc.*, vol. lix. (1896), p 207; vol. lx. (1896), p. 56.

[3] I speak doubtfully, because to my eye the interval from $D_1$ to $D_3$ (helium) appeared about equal to that between $D_3$ and the line in question, whereas, according to the measurements of Ramsay and Travers (*Roy. Soc. Proc.*, vol. lxiii., 1898, p. 438), the wave-lengths are:

| | | | | | |
|---|---|---|---|---|---|
| $D_1$ | ... | ... | ... | ... | 5895·0 |
| $D_2$ | ... | ... | ... | ... | 5889·0 |
| $D_3$ | ... | ... | ... | ... | 5875·9 |
| $D_5$ | ... | ... | ... | ... | 5849·6 |

so that the above-mentioned intervals would be as 19·1 : 26·3 [*June* 23.—Subsequent observations with the aid of a scale showed that the intervals above spoken of were as 20 : 21. According to this the wave-length of the line seen, and supposed to correspond to $D_5$, would be about 5855 on Rowland's scale, where $D_1 = 5896·2$, $D_2 = 5890·2$, $D_3 = 5876·0$.] I may record that the refractivity of the gas now under discussion is 0·132 relatively to air.

[4] *Phil. Mag.*, vol. xxxvi. (1893), p. 507.

He referred to the recent discovery of the mode of impregnation in some of the Cycadeæ by means of active spermatozoids, as in the case of vascular cryptogams. This seemed to suggest the question whether the gymnosperms were not more closely allied to the vascular cryptogams than was usually recognised. Did the evidence of palæontology favour the view that there was a closer affinity to the vascular cryptogams than to the higher section of flowering plants, the angiosperms?—The President said this question deserved careful consideration, but it should be remembered that in these strata they only saw four groups of plants, and that the coniferæ were found alongside the others, and were evidently living at the same period. Brogniart had shown the presence of pollen grains in the apical cavities of fruits which had been preserved in silex. It was not known how these spermatozoids were developed in Salisburia, but if they rendered pollen grains unnecessary, the presence of the pollen in these extinct fruits would be against the idea of including the gymnosperms with the cryptogams.—The President announced that the rooms of the Society would be closed from August 17 to September 17, and that the next ordinary meeting would be held on October 17.

### PARIS.

**Academy of Sciences,** July 9.—M. Maurice Lévy in the chair.—Problem of permanent heating of a sphere by radiation, reduced to the simpler problem of heating the same sphere by contact, by M. J. Boussinesq.—Combustible gases of the atmosphere; sea air. Existence of free hydrogen in the atmosphere, by M. Armand Gautier. By way of completing his previous researches on the impurities in the air of towns, woods and mountains, the author now gives the results of experiments on sea air. In these experiments no carbon compounds could be detected in 100 litres of air, the amount present, if any, being less than 0·03 mgr. per 100 litres; hydrogen was still found, however, to the extent of 1·21 mgr. for the same volume. The amount of free hydrogen thus proved to be present in the air, 2 parts by volume in 10,000, is thus about two-thirds of the carbon dioxide normally present.—On two loci relating to the densities of the liquid and saturated vapour of carbonic acid, by M. E. H. Amagat. In remarking on a recent paper by MM. Cailetet and Mathias, the author points out that the conclusions drawn, although opposed to his own, are obtained from the same set of experimental data. The law of rectilineal diameters, although extremely useful when applied within certain limits, is not a mathematical but an empirical law, derived from experiment, and hence its use as rigidly true seems hardly justified.—The chemical constitution of steel; influence of tempering upon the state of combination of elements other than carbon, by MM. Carnot and Goutal. In manganiferous steels, the state of combination of the sulphur is not altered by tempering, and phosphorus behaves similarly. In steels containing arsenic, the latter is free if the cooling has been slow, tempered steels containing an arsenide of iron, probably $Fe_2As$.—M. Czerny was elected a Correspondent for the Section of Medicine and Surgery.—On the equations of motion of a wire in any co-ordinates whatever, by M. G. Floquet.—On certain linear partial differential equations of the second order, by M. C. Guichard.—On the instability of certain substitutions, by M. Levi-Civita.—Demonstration of the rotation of the earth by Foucault's experiment with a pendulum 1 metre long, by M. Alphonse Berget. The sensibility of the reading apparatus is increased by viewing the pointer carried by the pendulum in the field of a microscope furnished with cross-wires in the eyepiece. With a pendulum only 1 metre long, the deviation can be clearly observed after four seconds.—On the liquefaction of gaseous mixtures, by M. F. Caubet. The results of experiments upon mixtures of methyl chloride and sulphur dioxide are here given in the form of curves. Two of the curves have the form predicted from theoretical considerations by Gibbs and Konovalow; these experiments being the first to show these points.—On a new type of mercury pump, allowing of a good vacuum being attained rapidly, by MM. Berlemont and Jouard. A drawing of the pump is given, unaccompanied by any explanation. It is claimed for this pattern that it will work with 12 lbs. of mercury, gives a high vacuum automatically, is not easily broken, and contains neither taps nor rubber connections.—On an ammoniacal chromous sulphate, by M. Ch. Laurent. The salt described, which has the composition $Cr(NH_4)_2.(SO_4)_2+6H_2O$ is analogous to the double sulphate of iron and ammonia.—On the preparation of gentopicrine and glucoside from fresh gentian root, by MM. Em. Bourquelot and H. Hérissey. The fresh roots are treated with boiling alcohol as soon as possible after picking, in order to prevent the action of the oxydases of the plant upon the glucoside, 22 kilograms of root giving 250 grams of crystallised gentiopicrine.—Experimental parthenogenetic segmentation in Amphibia and Fish, by M. E. Bataillon. The chemical composition of the medium, in which the eggs are placed, has only a secondary effect. The serum of mammals, whether diphtheritic or not, behaves like an isotonic solution of a salt or sugar; it acts by its osmotic pressure.—Lœb's theory of the chemical fertilisation of the egg, by M. Viguer.—On the cytology of the Hymenomycetes, by M. René Maire.—The experimental origin of a new vegetable species, by M. Hugo de Vries.—Influence of experimental modifications of the organism upon the metabolism of sugar, by MM. A. Charrin and A. Guillemonat.—A new method of measuring stereognostic tactile sensibility, by MM. Ed. Toulouse and N. Vaschide.—Some new facts concerning the subterranean river at Padirac (Lot), by M. E. A. Martel. The work done in 1899 and 1900 has rendered accessible another 400 metres of this underground river.—Combination of the effects of synodic and tropical revolutions of the moon, by M. A. Poincaré.

### NEW SOUTH WALES.

**Royal Society,** May 2.—W. M. Hamlet, President, in the chair.—Annual general meeting. Mr. W. M. Hamlet read an address upon the development of chemistry. Four words of Arabic or Egyptian source were taken as the text or frame work of this address, namely, alchemy, alkali, alkaloid and alcohol. Under the first came a brief review of the most prominent alchemists. The second afforded scope for the derivation of the word denoting the volatile alkali—the alkaline air—ammonia. In the case of the term alkaloid the researches of Fischer were referred to as showing the constitution of such alkaloids as theobromine and caffeine from structural formulæ of uric acid. Under the generic term, alcohol, the fermentation of other substances than those in use for the production of spirits of wine were dealt with. A vote of thanks was passed to the retiring president, and Prof. Liversidge, F.R.S., was installed as President for the ensuing year.

## *TRADE IN ANCIENT ASSYRIA.*

*Babylonians and Assyrians: Life and Customs.* By the Rev. A. H. Sayce. The Semitic Series. Vol. vi. Pp. x + 273. (London: John C. Nimmo, 1900.)

THIS little book belongs to a projected series of volumes which we gather are intended to deal with the Babylonians and Assyrians and other allied Semitic races, "the object of the series" being, according to the prospectus, "to state its results in popularly scientific form." The volume assigned to Prof. Sayce, which is the first of the series to make its appearance, describes the life and customs of the Babylonians and Assyrians, a subject which offers many points of interest to the general reader. Moreover, within recent years much new material has been published which has thrown considerable light on the social condition of the Babylonians and Assyrians during both the earlier and the later periods of their history. Thousands of clay tablets, which were unearthed at Telloh in Southern Babylonia and have found their way into the museums of Europe, contain temple-records, lists and inventories, receipts and tablets of accounts, and furnish a glimpse of the daily life of the early inhabitants of Babylonia at about 2500 B.C. The letters and commercial documents of the period of the First Dynasty of Babylon enable us to form a still more intimate acquaintance with the life of the Babylonians under some of the earliest of their Semitic kings; while the systematic publication of the legal and epistolary literature in the great collection of tablets from Kouyunjik has increased our knowledge of the social condition of Mesopotamia under the later Assyrian kings. Finally, the large collections of tablets of the Neo-Babylonian and Persian periods, which are now available for study, make it possible to trace the development of laws and customs down to the latest periods of Babylonian history. There is, therefore, no lack of material on which to base a sketch of the manners and customs of the Babylonians and Assyrians.

Prof. Sayce has written many popular books on this subject, and he is well qualified for the task he has undertaken; but we cannot help wishing that in one important point he had modified the plan on which he has compiled his volume. The book deals largely with small details, containing descriptions of sales of houses and lands and property, deeds of partnership, marriage contracts, receipts, records of loans, and numerous other commercial and legal transactions drawn from the thousands of "contract-tablets" which have been published in various monographs and in the transactions and journals of different societies. Any book describing the life and customs of the Babylonians must necessarily draw upon this large and scattered literature in order to illustrate the general conclusions which the writer formulates. Prof. Sayce has made abundant use of this material, quoting and describing tablets freely; on p. 16, for instance, in one short paragraph, he refers to no less than nine separate documents of different dates. But from the first page to the last he has not given a single reference to the works in which the various tablets have been published, or any indication by which they might be identified; in fact, not including Biblical quotations, we have only found two references in the book (on pp. 1 and 66), and these are to the opinions of modern writers and not to original authorities. This is perhaps not Prof. Sayce's fault, but a defect in the general plan of the series, for it is possible that the editor has ruled that references to authorities are incompatible with "a popularly scientific" treatment. But, whoever may be responsible, this defect detracts largely from the value of the book. No doubt the expert knows already where to look for the original texts quoted, and can control the various statements for himself; but the series is not meant for the expert. In the editorial preface, we are expressly told that it is intended to "be serviceable to students in colleges, universities, and theological seminaries, to the clergy, and to intelligent lay readers." The object of the work is, therefore, essentially educational; but without references it can prove but a poor guide or introduction to the study of the subject of which it treats.

Although doubtless hampered by this deficiency in the general plan of the work, Prof. Sayce has produced a very readable, though perhaps a rather rambling, little book. He has written attractively on the general character of Babylonia and its inhabitants, the constitution of the family, the system of education, commercial and social life, laws and government, letter-writing and religion. To treat all these subjects fully in some two hundred and sixty octavo pages is, of course, impossible; but the author has touched his subjects lightly, and some of his chapters contain valuable summaries, as, for example, that in which he describes the legal condition of women in Babylonia. The plan of writing vaguely without reference to authorities, however, is not conducive to strict accuracy, and we occasionally meet with a rather misleading generalisation. The statement on p. 102, for instance, that

> "no deed was valid without the seal or mark of the contracting parties"

is not borne out by the facts, for many deeds of different periods are extant which bear neither seal-impression nor nail-mark. On p. 61 we are told that

> "the year was divided into twelve months of thirty days each, an intercalary month being inserted from time to time . . ."

Even for the Assyrian period this statement is probably not accurate, and it takes no account of the changes which the calendar underwent in the long course of Babylonian and Assyrian history. The arrangement of the calendar and the method of harmonising the lunar and solar years are not yet accurately known in many of their details and are still subjects of controversy, but the student would not gather this from Prof. Sayce's statement. The evidence for cremation (pp. 62 ff.) among the Babylonians and Assyrians is far from being conclusive, and many scholars hold that it was not practised in Mesopotamia before the Parthian period. The statement on p. 51 that the writing of the scribes was sometimes so minute that magnifying glasses were used for reading by the Assyrians, and that short sight "must have been common in the Babylonian schools," is, to say the least, rather fanciful, the only evidence for the statement being a circular crystal object found by Layard at Nineveh, and thought to be a lens, but the use of which is unknown. That there was ever "a monotheistic school" at Erech (p. 262) would, we think, be difficult to prove, and the evidence for "human sacrifice" referred to on p. 103 should surely have been given. It is, no doubt, a consequence of the omission of references that we sometimes come across repetitions in the book, as, for instance, the quotation referring to the Chaldeans and their ships in connection with Eridu on pp. 9 and 183; the suggested identification of Sar-ilu with Israel on pp. 17 and 191, the description of the letter referring to a ferry-boat on pp. 186 and 215, &c. Misprints, too, are not uncommon, as, for example, "the eighteen-hundredth*s* part" (p. 114), "I will *lie* up five shekels of silver" (p. 225), "Emutalum" for "Emutbalum" (p. 211), "weight" for "night" (p. 266), "bears" apparently for "beasts" (p. 52), "cunei-plain" apparently for "plain" (p. 211), and on p. 157 we are told that "Aramaic became the *lingua panca* . . . in the commercial world." Prof. Sayce is probably not to blame for such misprints, for the American editor was doubtless responsible for the correction of the proof-sheets.

---

## *ELECTRICAL ORGANS. MUSCLE OR NERVE?*

*Beiträge zur Physiologie des elektrischen Organes der Zitterrochen* (*Torpedo*). By Siegfried Garten. Pp. 116, 4 plates. (Leipzig: Teubner, 1899.)

ALTHOUGH electrical fishes have been the object of scientific curiosity and investigation for nearly 300 years, it is only in the last half of this century that physiologists have realised the great importance, for general physiological problems, of the phenomena presented by these remarkable animals. The discovery and investigation of the electrical phenomena accompanying excitation or activity of all the excitable tissues in the animal body have rendered it of supreme importance to attack the problem and the causation of these electrical changes in the organ, where the "electrical function," so to speak, attains its highest degree of development. It seems probable that electrical organs may be developed by the transformation of many different kinds of tissue. In the greater number of these fishes, however, including that which is the subject of the memoir under consideration (Torpedo), the organ is formed by a transformation of embryonic muscle-fibres, accompanied by a disappearance of the cross-striated contractile material, with a great hypertrophy of the nerve-endings. The electrical discharge of the organ, with an E.M.F. probably amounting to 100 to 200 volts (Gotch) and lasting about 6/1000 of a second, may be excited reflexly or by excitation of the nerve to the organ, or, using strong shocks, by stimulation of the organ itself. The direction of the current in the fish is from ventral to dorsal surface. The electrical organ in the torpedo consists of an array of columns, each column being composed of about 400 transverse discs representing the electromotive elements of the organ. On the ventral surface of each of these discs we find the complicated terminal arborisation or network of a nerve-fibre, embedded in granular protoplasm, and separated from the disc by the remains of the primitive muscle-fibre from which the organ was developed.

We must assume that it is in consequence of these structural arrangements that the excitatory electrical change in the whole organ, instead of passing from one end to the other as a wave, and so giving rise to a diphasic variation of small extent, causes merely a change in one direction, which is summated in proportion to the number of discs in the pile, so producing a monophasic variation of considerable E.M.F. It is evident that we could conceive of each disc as consisting of an inferior part, which is excitable and therefore capable of the chemical changes associated with excitation, and of a superior part, structurally and chemically continuous with the inferior, but incapable of excitation. The question at once arises whether these two parts are represented by nerve and muscle, or whether the chief excitatory change takes place in some of the structures derived from the embryonic muscle-fibre. Is the electrical change an action current of nerve-ending or of muscle?

Du Bois Reymond, for theoretical reasons, supported the latter view, and at the same time laid great stress on a remarkable property of the organ. He found that the electrical conductivity of the organ was greater for homodromous currents, *i.e.* those in the direction of the discharge of the organ, than for heterodromous. It was shown later by Gotch that this irreciprocal conductivity is only apparent, Du Bois Reymond's results being due to the fact that, in measuring the current passing through the organ, he was measuring the algebraic sum of the battery current and the current excited in the organ itself. Naturally, therefore, the homodromous current was greater than the heterodromous.

Gotch has also drawn attention to the fact that in the electrical organ we have an opportunity of deciding the nature of the demarcation-current consequent on injury. Since in this organ the demarcation-current is always in the same direction as the excitatory-current, whatever may be the position of the injury, he concludes that the demarcation-current or current of rest is really in all cases an action-current due to the continued stimulation at the seat of injury.

On these three questions, but especially with regard to the nervous or muscular nature of the excitable tissue, additional evidence is furnished by Garten, whose research is devoted chiefly to the elucidation of three points—the effect of nerve-section and subsequent degeneration on the direct excitability of the electrical organ; the effect of drugs, such as curare, which are direct poisons for nerve-endings; and the action of veratrin as a specific muscular poison.

The results of these experiments are a strong confirmation of the views put forward by Gotch. During the first eight days after section of the nerves, the organs can be excited either directly or indirectly; from the eighth to the eighteenth day after section, the organ can be excited to discharge, but the shocks are weaker than normal. After the nineteenth day, however, no response is obtained to stimulation either of the nerve or of the electrical organ itself. Thus the irritability of the organ disappears with that of the nerve, whereas a muscle is excitable long after the degeneration of its motor nerve with end-plates is complete. It may be mentioned that the organ-current, or current of rest, and the irreciprocal conductivity diminish during the period of lowered irritability of the organ, and are absolutely abolished after the nineteenth day, thus pointing to the excitatory nature of both these sets of phenomena.

The experiments on the action of curare are less satisfactory, owing to the enormous doses (1 grm. for a fish of 1200 grms.) which are necessary to paralyse the indirect excitability of the electrical organs. Since in these large doses the curare excites central discharges, it is necessary to cut all the electrical nerves to prevent paralysis by fatigue. In this case, however, with a sufficient dose of curare, direct and indirect excitability are abolished simultaneously. The same interdependence of direct and indirect excitability is observed in paralysis by fatigue, in marked contrast to the behaviour of voluntary muscle, where a muscle on direct stimulation gives a practically normal contraction after complete fatigue by stimulation of its nerve.

Veratrin, which causes a marked prolongation of the excitatory change in skeletal muscle, was found by Garten to produce a somewhat similar effect on the electrical discharge of the torpedo. This drug, however, diminishes and very rapidly abolishes the direct and indirect excitability of the electrical organ, and no proof is afforded that the prolonged response may not be due to the state of artificial "fatigue" produced by the drug, or that it is in any way specific. Waller's experiments have shown that veratrin has practically no action on the nerve, and although Garten quotes certain of his own experiments which appear to indicate an action of this drug on non-medullated nerve, the strength of the solution employed must be regarded as too great for the demonstration of the specific action of the drug.

We cannot, therefore, regard the experiments with veratrin as detracting in any way from the support afforded to the nerve-ending theory of excitation by the results of nerve-section. It is remarkable that a change which, as the current of action in nerve, needs all the appliances of a well-fitted laboratory for its demonstration, should, by a mere subdivision of the fibrils and their enclosure in compartments separated by non-excitable partitions, be able to produce the strong shocks of high intensity which characterise the discharge of the whole organ. No better demonstration could be afforded of the futility of those hypotheses which would explain the passage of the nerve-impulse as a mere propagated polarisation, and would deny any energy-producing changes in the axis-cylinder itself. The absence of fatigue in medullated nerve does not imply absence of chemical change, but merely equivalence of disintegration and reintegration, an equivalence probably connected, as Waller has suggested, with the presence of a medullary sheath.

E. H. S.

## FLUORINE.

*Le Fluor et ses Composés.* Par M. Henri Moissan. Pp. xii + 396. (Paris: G. Steinheil, 1900).

THERE could scarcely be a greater contrast than that between the gaseous substances most recently added to our list of elements; fluorine on the one hand, argon and its companions on the other. The existence of the hypothetical element fluorine was postulated in many well-investigated compounds as early as the beginning of the present century; yet, on account of its intense chemical activity, fluorine was not prepared as a free element until 1886, despite the numberless attempts which had been made to isolate it in the intervening period. Argon, on the other hand, owing to its absolute inertness, and to the fact of its occurrence along with the very inert nitrogen, led an unsuspected existence until 1894, although it was contained in enormous quantities in the atmosphere—a constant subject of investigation. The compounds of fluorine, then, were known long before the element itself,—compounds of argon are still wanting. Indeed, as has been pointed out (Sedgwick, "Argon and Newton," p. 2), the name element in the ordinary sense cannot properly be applied to argon and its companions at all, since that term implies the existence, or at least the possibility of existence, of compounds concerning which we are still in total ignorance. As yet there is no chemistry of argon.

The time, however, has now arrived when fluorine and its compounds can be brought under review so as to give a picture of the element in itself and in its combinations, which in main outlines, at least, may be looked upon as final. Prof. Moissan was obviously the man to execute this task; he has fortunately undertaken it, and the book before us gives the result of his labours. As evidence of the extent of the author's research, we may adduce the bibliography given as appendix, which occupies eighty-five pages, and contains references to about six hundred books and papers. These references are arranged alphabetically according to authors, and also chronologically, beginning with Agricola, 1558, and ending with the year 1899.

In the book itself the author's investigations have naturally the first place, and one of the chief points of interest is that M. Moissan not only gives us an account of his apparatus, experiments and results, but also of the leading thoughts which guided him from one experiment to another, until the culmination was reached in the liberation of the gaseous element. The student beginning research could not find a more stimulating record of failure and eventual success than that afforded in Chapter i., on the isolation of fluorine. Chapter ii. deals with the most recent apparatus for the production of fluorine by electrolysis. At a temperature of about −80°, attained by the evaporation of a mixture of solid carbonic acid and acetone, it is possible to use an electrolytic vessel of copper instead of platinum, provided that the hydrofluoric acid employed is free from water. This substitution brings elementary fluorine within the scope of any well-equipped chemical laboratory. Chapter iii. deals with the physical properties of fluorine, its liquefaction, and the action of the liquid on various substances. In

Chapter iv. we have a systematic account of the action of fluorine on the non-metallic elements and on some of their compounds, together with a somewhat detailed study of the non-metallic fluorides. The action of fluorine on the metals and their compounds forms the subject-matter of Chapter v., the organic fluorine compounds receiving treatment in Chapter vi. The last chapter in the book deals with the atomic weight of fluorine, the volumetric composition of hydrofluoric acid, the action of fluorine and hydrofluoric acid on glass, and the position of fluorine in the system of the elements. The author definitely places fluorine at the head of the halogen family, sufficient stress, however, being laid on the points in which fluorine resembles the elements of the oxygen family; such as the ease with which it unites with carbon, and the analogies exhibited by hydrofluoric acid to some dibasic acids. A short summary of the properties of fluorine concludes the volume, and for frontispiece there is an excellent portrait of the author.

The book is as interesting as a monograph can well be, and M. Moissan has earned the gratitude of all chemists by thus placing before them a connected record of one branch of his splendid activity. J. W.

## OUR BOOK SHELF.

*A Text-Book of Physical Chemistry.* By Dr. R. A. Lehfeldt. Pp. xii + 308. (London: Edward Arnold, 1899.)

A FEW years ago the teacher of physical chemistry seeking a suitable elementary text-book, dealing with the more recent developments of the subject, which he could put into the hands of a class of students approaching the study of physical chemistry for the first time, was somewhat embarrassed to find one. This state of things is now changed for the better by the recent appearance of several very excellent works; among these Dr. Lehfeldt's book will take a high place. The author explains in his preface that the book "is intended to contain what a student—with limited time and many subjects to learn—may usefully read. It is by no means written to suit any examination, but still is written with the practical requirements of students in view."

Dr. Lehfeldt has succeeded in avoiding the unessential and in explaining the fundamental ideas of modern physical chemistry in a thoroughly lucid manner, so that a student who has grasped the contents of this book will experience little difficulty in appreciating the meaning of the larger handbooks or original memoirs.

An introductory chapter on physical units will be useful to chemical students, who are, perhaps, apt to be slipshod in such matters. This is followed by a chapter on molecular weights in gases and solutions, which includes electrolytes and the ionic theory, and by a very well-considered chapter on the connection between physical properties and chemical constitution. The principles of thermodynamics are then explained; and the two laws (*a*) of chemical equilibrium in a system of perfect gases at constant temperature, and (*b*) of the influence of temperature on chemical equilibrium are deduced from them. This chapter presupposes some knowledge of the elements of the calculus, but any student who wishes to understand physical chemistry must make up his mind to acquire the small amount of mathematical knowledge requisite.

The applications of the two thermodynamic theorems to chemical change and equilibrium in homogeneous and heterogeneous systems are then taken up. This treatment has the great advantage that the whole of the phenomena can be grouped in a very simple way, the close relationship of chemical and physical change is clearly brought out, and the student is not bewildered by the apparent multiplicity of the phenomena. The book concludes with a brief but most interesting chapter on the theory of the galvanic cell, and the connection between electromotive force and chemical affinity. The book may be unhesitatingly recommended as one of the best of its kind.

The only misprint we have noticed occurs on p. 141, line 18, where "increases" is written in place of "decreases." T. E.

*An Introduction to Analytical Chemistry.* By G. G. Henderson, D.Sc., M.A., and M. A. Parker, B.Sc. Pp. 228. (London: Blackie and Son, Ltd., 1899.)

THIS is a compact work covering the ground of ordinary qualitative analysis as well as the tests for a number of organic substances, and also containing an account of the most important processes of quantitative analysis.

Without being designed on any new plan or being explanatory to the fullest extent, the book is written in a scientific spirit. The authors state that they have made free use of the works of Dittmar and others, and it is perhaps not uncomplimentary to remark that the influence of that sterling chemist is apparent in the book.

The directions for work are clear and practical, and the analytical methods quite satisfactory. Perhaps the least useful part of the book is that dealing with organic substances and their separation from mixtures. This branch of analytical art is very difficult, and the particular form of it, which has been encouraged by certain examining bodies, has brought disaster to many a good student. It is difficult to understand what useful purpose is served by the efforts of second-year students to prepare for recognising the constituents of, say, a mixture of urea and an inorganic salt. It is of no importance to medical men, it does not help the teaching of organic chemistry, and it crowds out practical work which would be of real value. The examination of such mixtures is a matter for an analyst of mature knowledge and experience. A. S.

*Maryland Weather Service.* Vol. i. Pp. 566. (Baltimore: The Johns Hopkins Press, 1899.)

THE Maryland State Weather Service was established in 1892, and its reports and climatic charts are favourably known to meteorologists. In 1896 a plan of closer co-operation between the National and State Weather Bureaux was proposed by Prof. W. L. Moore and adopted. This marked the commencement of a new and very important period in the history of the Service, and the present volume is the first published since the two organisations have been in close connection. The energies of the Service are now to be devoted chiefly to the publication of special reports on the climatology of the State, and if the volume before us is to be taken as an earnest of future ones, we may be pardoned a feeling of envy at the sumptuous way in which scientific work of this kind is presented to the public in America. We notice that it is proposed to publish in the near future a full account of the climatic features of Maryland, in which the physiography, meteorology, hydrography, medical climatology, agricultural soils, forestry, crop conditions and the fauna and flora of the State will be considered.

The present volume is confined to the physiography and meteorology, and includes an introduction by Prof.

Bullock Clark, on the establishment and organisation of the Maryland Weather Service; a description of the physiography of Maryland, by Dr. Cleveland Abbe, jun.; a report on the meteorology of Maryland, by Dr. Abbe, Mr. F. J. Walz and Dr. O. L. Fassig; and a contribution on the aims and methods of meteorology, by Prof. Cleveland Abbe, already noticed in these columns (vol. lxi. p. 448). The illustrations are numerous, instructive, and of a very high class, most of them being full-page collotype plates or lithographs. No State or country has given to the scientific world a volume in which the operations of the "Weather Service" are interpreted more liberally, or the work presented in a more elaborate *format.*

*Volta e la Pila.* By Prof. Augusto Righi. Pp. 40. (Milan: Tip. Bernardoni di C. Rebeschini, 1900.)

THIS is an inaugural discourse delivered by Prof. Righi on September 18, 1899, at the National Electrical Congress at Como. It deals with (1) the science of electricity prior to Volta; (2) the scientific work of Volta considered apart from his discovery of the pile; (3) Galvani's discovery of electricity of contact; (4) the pile; (5) the theory of the pile; and (6) conclusions. In an appendix, Prof. Righi gives a note on the theories of the pile, in which he expresses favourable opinions on the "osmotic" theory.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### An Optical Phenomenon.

IN connection with Prof. Simon Newcomb's letter on "Terrestrial Gegenschein" (NATURE, October 5, 1899) and the subsequent letters of Mr. Mallock (NATURE, October 12 and November 9, 1899), I desire to call attention to an analogous and very beautiful phenomenon of perspective which I should have mentioned at the time but that the winter season of the year is not favourable to its observation in this country.

When the sun is high and shining brightly in a clear sky, let an observer stand so that the shadow of his head falls on the surface of water that is deep, clear, but not quite clear, and slightly agitated by the wind. He will observe that from the place where the shadow of his head falls shafts of light seem to radiate in all directions. When once well observed, the phenomenon is very striking, but it has surprised me to find how few persons have noticed it. I first observed it many years ago, when I used daily, about mid-day in summer, to cross the bridge over the channel leading to the boat store in the Portsmouth Dockyard, near the main entrance. But it was not till a year later, on Ulleswater, that I found the explanation. The lake was there turbid in parts from the washings of mines, but quite clear in others. Standing up in a boat, one could see the phenomenon very clearly where there was very slight turbidity, but not if the water was quite clear, nor if there was much turbidity, and never in a dead calm. This gave the explanation. The convexities of the surface, when there is a slight agitation, acting as lenses, split up the otherwise uniform illumination into separate, parallel shafts of light, each consisting of slightly convergent rays, which, traversing the liquid, are rendered visible by the suspended particles that they illuminate. These shafts seen in perspective have their point of apparent convergence exactly opposite to the sun, *i.e.* in the shadow of his head. If the water is smooth, there are no particles to illuminate and reveal the shafts; if too turbid (or too shallow), the light does not penetrate far enough. If the sun be too low in the sky, too little light enters the water; if it shines through clouds, so that the source is diffuse, a uniform illumination results. Hence the rays are not easily noticed in winter.

After the phenomenon has once been well seen under such circumstances as I have described, one can hardly enter a boat on a bright day without being haunted by it, and realising that, although the shadow of one's head may not actually fall on the water, yet every streak of light in the water radiates from it.

A. M. WORTHINGTON.

R.N Engineering College, Devonport, July 22.

### Temperatures of Recently Killed Chamois.

MR. E. N. BUXTON, in his fascinating "Short Stalks" remarks (p. 38, footnote): "A friend of mine once took the temperature of a freshly killed chamois, and it stood at 130° F." There is no doubt that many professional chamois hunters believe that the temperature of the animal is considerably higher than that of domestic animals.

During the last three years I have determined the rectal temperature of twenty-nine recently killed chamois.

These may be divided into three classes.

A.—*Those successfully stalked and dropped dead by the first shot.* (12 observations.)

With two exceptions, the temperatures, taken in every case within five minutes of death, lie between 101°·1 and 101°·9, the average being about 101°·5 F., or 38° 6 C.

The two exceptions were (i.) a kid four or five months old, the temperature of which was 103°·2 F., or 39°·6 C., and (ii.) a doe which had received a severe flesh-wound in the back eight days previously, the temperature of which was 102°·4 F., or 39°·1 C.

B.—*Those shot au galop.* (7 observations.) These animals all dropped dead in their tracks, or died almost immediately.

The temperatures on the whole were found to be distinctly higher than in class A, being 101°·5, 102°·3, 102°·4, 102°·9, 102°·9, 103°·5 and 104°·5 respectively.

The first four of these had run from 40 to 50 yards, the fifth about 200 yards, and the last two about 100 yards. The last two were young bucks, which, to judge from the appearance of their incisor teeth, were four and three years old respectively.

C.—*Those wounded at the first shot, but only brought to bag after some interval.* (10 observations.)

Here the temperatures are, on the whole, still higher.

The lowest (101°·7) was that of an animal which ran 50 yards after the first shot, and was then dropped dead by a second.

The next (102°·4) ran about 300 yards. The third (102°·9) was wounded in the stomach, then walked about 250 yards towards me, and was dropped by a second shot at about 30 yards.

The fourth (103°·1) ran about 200 yards. The fifth and sixth (103°·3 and 103°·5) were shot through the kidneys, but were not killed outright by the shot.

The remaining four showed temperatures of 104°·9, 105°·6, 106°·2 and 106°·7.

Of these the first had its fore-leg broken, and was recovered twelve hours later.

The second and fourth were recovered about half an hour after being wounded.

The third was an animal whose hind-leg was broken. It then escaped into another valley, and hid itself in a cave on a rock-wall, where it was spied about four hours later. A second shot failed to hit it, but drove it out of the cave. It then tried to climb the steep rocks above it, and after twice failing to overcome a *mauvais pas*, slipped and fell about 100 feet, and was killed by the fall.

Results similar to these were obtained in 1898 by a Swiss friend of mine. Some of the animals were driven by dogs, and these always showed a higher temperature than those stalked and killed by the first shot, the temperatures of the driven animals varying from 103°·6 to 105°·8.

The highest temperature obtained by him was 107°·6 (42° C.). This was an animal which was severely wounded in the back, then lost till twenty-four hours later, when it was found and killed by a dog.

How far the average temperature given under A represents the normal temperature of the living chamois, I am unable to say, because I do not know to what extent sudden death by a bullet would be likely to affect the reading of the thermometer. Perhaps some physiologist would kindly throw some light upon this point.

To save the trouble of calculation to any foreign reader who may see this letter, I may add that 38° C. = 100°·4 F., 39° C. = 102°·2 F., 40° C. = 104° F., 41° C. = 105°·8 F., 42° C. = 107°·6 F.

G. STALLARD.

Rugby, July 12.

### The London Mathematical Society.

A FEW months since it was announced in your columns that the Society had directed an index to the first thirty volumes of the *Proceedings*, and a complete list of members, to be drawn up by the secretaries. These have now been issued to members: the general public can have them from the publisher (F. Hodgson, 86 Farringdon Street) at the respective prices, 2*s*. 6*d*. and 6*d*. A free distribution of 1000 copies of the first part of the index, which comprises an arrangement of the papers in alphabetical order of authors' names, has been commenced, and upwards of 500 copies have been sent out. In the course of the existence of the Society some 440 persons have been recorded on the roll. This is not a great number, and some younger societies have shown greater vitality. Perhaps this issue may lead to the Society becoming more widely known. R. TUCKER.

### The Consultative Committee and Technical Education.

THE Council of the Association of Technical Institutions has had under consideration the "Draft Order in Council" constituting the Consultative Committee of the Board of Education.

It welcomes the appointment of the Vice-President of the Association, Mr. Henry Hobhouse, M.P., as a member of the Consultative Committee, and as a representative of agricultural education and of technical education in rural districts. But it views with astonishment and regret the fact that technical education in the great towns of the United Kingdom is wholly unrepresented, although there are upon the Consultative Committee two representatives of elementary education in the persons of the Dean of Manchester and Mr. Ernest Gray, M.P., three heads of secondary schools, viz. Mrs. Bryant, Dr. Gow and the Hon. and Rev. Edward Lyttelton, as well as a large number of persons intimately acquainted with literary education.

It seems to the Council a matter of the greatest national importance that there should be upon the body which is to advise the Board of Education an adequate number of persons who are well acquainted with the applications of scientific knowledge to industries and commerce, and with the best methods of giving such technical training in this country as shall enable us to meet successfully foreign competition.

In view, therefore, of the very serious damage which may be done to technical education, and thereby to the trade and commerce of the country, if the Committee to which the Board of Education will look for advice is composed of persons without adequate knowledge of the matters to which I have referred, I venture to ask you to allow me, through your columns, to draw the attention of Members of Parliament, manufacturers, and merchants to this subject, in the hope that they may take steps to secure that the constitution of the Consultative Committee may be modified in such a way that due provision may be made for the presence of persons possessing special knowledge of trade, manufactures, and technical education.

Merchant Venturers' Technical College, Bristol, July 21.

J. WERTHEIMER. (Hon. Sec.)

## *THE CENTENARY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.*

THE Royal College of Surgeons of England celebrates its centenary on July 25–27. The actual month of course in which George III. founded the College by Royal Charter was March, 1800, but in the spring of 1900 it would have been impossible adequately to marshal the forces of English surgery. Sir William MacCormac and Mr. Frederick Treves, to name no others, were, if we remember rightly, still in South Africa. The belated birthday of the College is to be fitly commemorated by a grand degree-giving, at which a number of representative European and American surgeons will receive the newly-created distinction of Hon. F.R.C.S. H.R.H. the Prince of Wales has already been presented with the diploma of Honorary Fellowship, a deputation from the College having waited on him on July 24. The form of words used in the Royal diploma is the same as that employed in all cases. "Know all men by these presents, that we, the Royal College of Surgeons of England, do hereby admit his Royal Highness Albert Edward, Prince of Wales, an Honorary Fellow of the College."

Besides the degree-giving there will be a conversazione, a grand banquet, a Presidential address of welcome, which will deal at length with the history of the surgeon's art, and a reception at the Mansion House. But all such august ceremonial should be regarded neither as an end in itself, nor as specially typical of the progress of surgical education.

The centenary of the Royal College of Surgeons marks, in fact, not so much the hundred and first birthday of a noble institution as the audit-day of English surgery. It is as such that it should be regarded by all thoughtful men. How stands the surgical art of to-day in comparison to that of the opening years of the century? The question requires no long answer: it is not necessary to deal at length with the profound revolution, wrought since the days of Hunter, in surgery, whether intra-cranial, intra-thoracic, or abdominal. It suffices to mention only anæsthesia and antisepsis. In the year 1800 these two great agencies for good were unknown—the surgeon had to arm himself for his task after the manner of a skilled slaughterer, and Death, as often as not, stalked at his elbow through the hospital wards or to the rich man's bedside.

At the beginning of the century, too, science was everywhere in its infancy. The surgeons, though they had ceased to rank with manicurists and barbers, were often little better than bone-setters. They dreaded operations—considered them a confession of weakness, and this through a general ignorance of how safely to operate. Medical etiquette, in those old days, was an affair of various interpretation: quackery preyed unreproved on the general ignorance. To-day surgery has become, as far as may be, scientific. The modern medical man is trained as a man of science; he is in England also subject to perhaps the severest code of honour known to history. The scientific spirit has so far permeated the public mind that even modern quackery is compelled to pose in the garb of research based on the inductive method. Graham, Buzaglo, and the inventor of the "metallic tractors" appealed in the year 1800 to just such confused instincts as possess the affrighted victims of the savage medicine-men described by Messrs. Spencer and Gillen. To-day the clever impostor takes in vain the sacred name of science, or if he make his appeal to the religious instinct, he is careful to do so almost as philosophically as a Brahmin or a Buddhist.

The progress of social relations is spoken of by jurists as one from status to contract; the progress of the medical sciences might as fitly be described as from fetich to reason.

In this progress the Royal College of Surgeons has been no unimportant factor. The very conservatism of that great society has been a source of strength. In countries where leading institutions are less tenacious of privilege, less rigidly decorous, the interests they protect tend incessantly to degenerate for lack of ideals, of ethics, and of breeding. The names of countries, especially young ones, will occur to the philosophic, where the medical profession suffers continuously from the unacademic spirit of its academies. Yet there can be no doubt that the conservatism of the College was at one time excessive.

This will be at once apparent to the readers of Sir William MacCormac's centennial address on the "History of Surgery and Surgeons." As a succedaneum to his text, sixty-one carefully prepared biographies of his predecessors in office have been published. Of these presidents certain of the earlier ones constitute an object-lesson in oligarchy and the art and craft of office-holding. Charles Hawkins, first Master of the College in 1800, had for years—since 1790—been Master of the old civic Corporation of Surgeons. Indeed, it died, through inadvertence, under his rule. He belonged to an office-holding race. His father, Sir Caesar Hawkins, the first baronet, and his uncle, Quennell Hawkins, both St. George's men, where office was bought for large sums of money paid to seniors, had been Serjeant Surgeons to George II., and as such were liable to accompany him on his campaigns. Whether they did so is doubtful; it was Ranby who attended the gallant little king at Dettingen. Charles Hawkins enjoyed the honours of the same office, which take us back in thought to Homer's Machaon and Podalirius, and to the Sanskrit word "Shalya," "an arrow-head," or "surgery." But beyond this we know very little of Charles Hawkins. There are others like unto him whom we need not specify. The "Dictionary of National Biography" knows them not. Their peculiarity was silence, "the fool's best friend." Conjointly they published nothing; an aversion to intellectual exertion seems to have distinguished them. But we can imagine them at least as strict upholders of dignified routine, as courtiers, as men of the world. The delightful eighteenth century died very hard in England—in Latin countries it is not dead yet—and these old gentlemen, with their powdered hair and voluminous cambric cravats, seemed to carry on the tradition of an ample age, where a fine face, a white hand, and a capacity for classical quotation fitted an average great man for any sort of position from the Papal chair to the presidency of the English College of Surgeons. Others there were, however, even in the early days of the College history, who struck a different note. Such were the terrible Abernethy, a man driven into savagery of manner by his innate sense of justice, which abhorred the quacks of his day and generation and their self-indulgent victims, suffering from avoidable ills, chiefly due to the effects of over-feeding and the "*alcoolisme des gens de bon ton.*" Such also the variable Lawrence, an early Darwinian, a passionate reformer and reform journalist, in association with the famous Wakley, an eloquent orator, and, in the end, a conservative College Councillor of the strictest.

In the College Library and Council Room during the centenary celebrations, an exhibition is being held of portraits, busts, relics and manuscripts illustrative of the history of the College, and this in itself bears witness to the changes which a hundred years can bring forth. Among the exhibits never, we believe, shown before, but now sanctioned by the lapse of long years, are papers of importance from the Owen collection. Here, for instance, is the Curator Clift's determined evidence against Sir Everard Home, Bart., who plagiarised from Hunter's papers and then destroyed them. In one exhibited letter Clift quotes Sir Everard's words, "all gone, every Jack of them," in reference to Hunter's descriptions of cases and specimens. This is not the place to discuss the Home—Hunter controversy, which has long ago been given over by the experts, but we may be allowed a postscript. The question between Hunter and Home should be judged from the point of view of 1820. Home was an old-fashioned Scotsman of a proud and ancient stock. Hunter came of a race of "bonnet-lairds." Home looked indulgently down on his brother-in-law, Hunter. These family sentiments are almost incomprehensible to an Englishman, but they rage even in the Scotland of to-day. Home thought he might fairly make use of his humbler connection's notes. He was no academic—had no scholarly regard for literary *meum* and *tuum*. How few have even to-day? Hunter's notes, on the other hand, to judge by the remaining specimens of them, were extraordinarily rough and often illiterate, though at all times they betray the great and ardent mind fretting and hurrying under inadequate powers of expression. William Clift also, John Hunter's amanuensis and subsequent defender, has been described by one who knew him well as a typical Cornishman, extremely garrulous, prone to repeat himself. There is in the College Library a "solander," *alias* box, full to the brim almost of Clift's repeated indictments against Home. The thing suggests "*idée fixe*."

Still, though Home acted according to the lights of his day and his order, he committed a crime of magnitude, and owing thereto the history of the great Hunterian Museum since 1800 has been necessarily one of re-construction. Clift began re-writing the Catalogue as it were from memory. He had worked so long with the great John Hunter that he knew how the master would have again spoken of numbers of specimens of which Home had burnt the descriptions. Richard Owen, Clift's son-in-law, was to Clift very much what Clift had been to Hunter. The young man worked ardently under his directions, sometimes aided by Benjamin Brodie, in his youth a zealous comparative anatomist. In one of his Museum Reports Richard Owen yearns for the days when Clift, and he, and a very few others, including Everard Home, worked incessantly in the Museum-room, undisturbed by the visits of students and sightseers.

The public were indeed discouraged from visiting Hunter's collections, not in any gross spirit of obscurantism, but half-unconsciously, half-hieratically, much as a modern undergraduate reading for a Pass degree is kept at arm's length by the learned Don who is the College librarian. In 1833 Earle, lecturing on the urinary apparatus, gave vent to one of those petulant outbursts which are more illuminating than pages of studied prose. The passage, now often quoted, appears in the *Lancet* of the period, and is a bitter satire on the uncatalogued and dusty condition of the then Museum. Earle, it seems, had searched in vain for hours for pathological specimens with which to illustrate his remarks. The whole amusing tirade, if we remember rightly, was discreetly suppressed by him in his republished lecture.

At the present moment the great Museum—and the Library, too, for that matter—can be read like a book. One of the most notable publications of the centenary is the first portion of the "Physiological Catalogue," which, with its finely executed plates, will remain an enduring monument to the graphic skill and scientific acquirements of the Conservator and his staff.

The Museum, the Library, and the College owe their being, as it were, to John Hunter; but their emergence from the coma of the first three decades of the century is in great measure due to Sir Richard Owen. It is notable that the moment he begins to lecture in 1835, Wardrop's grumbling commentary in the *Lancet* undergoes a change. It seems at first as though the serious young Conservator was not understood. What did he aim at? why should he do so well where others had wrought so indolently? Then gradually the *Lancet* critics change their tone, and bless where before they had cursed.

A lecture by Owen became in time one of the great social and intellectual functions of the London world. Science was not then so specialised as it is to-day, nor perhaps so divorced from the interests of the literary. Bishops presided over the British Association; hereditary peers over the Royal Society; the Prince Consort took an interest in microscopy; the poets had not yet become decadent or æsthetic; the Tractarian movement had not yet replunged the world of women in the ages of faith. The public mind, indeed, would seem to have been more liberal than now. To this mind—alert, interested, deeply curious—Owen addressed himself with zeal. It is singular to note, at this distance of time, that his lecture would end with a debate, in which the Dean of St. Paul's would heckle the professor.

The College Lectures became still more important when Huxley succeeded to the chair Owen had once occupied. Owen retired in 1855, after delivering a course on "The Structure and Habits of Extinct Vertebrate Animals." He had prepared a course for 1856, when, however, lectures were suspended. The Council, it seems, had carped at the long duration of Owen's catalogue-making, and Owen had addressed to them an eloquent *apologia* for his seeming delays. Hence, perhaps, Owen's retirement. In 1863 Thomas Henry Huxley began to lecture, his first course dealing with "The Structure and Development of the Vertebrate Skeleton." His first lecture was devoted to the glyptodon with much-broken carapace, now in the Museum. He continued to deliver a long annual course till succeeded by Flower in 1869. The late Sir William Flower's tenure of the chair, which he shared with the great but somewhat neglected William Kitchen Parker, brings us down to comparatively recent times.

It is as a lecturing body that the College should prove most interesting to the world of Science at large. The names of Owen and the greater Huxley link it with the grand world of Cuvier and Darwin. We might write at length of the beneficent work of the College in pathological anatomy, or serum-therapeutics, a work all the more praiseworthy because it has been sedulously and quietly carried on in despite of the clamours of a stupid section of the public. Of the College examinations it would also be possible to say much. As recently, it should be remembered, as 1860 a doctor could qualify without passing a written examination in medicine. Now, of course, it is scarcely possible, in view of the examinations of the Conjoint Board of the Colleges of Physicians and Surgeons, for any impudent dunderhead to launch himself in practice, and to pocket the fees of a public always a little in love with quackery and mystification. Of the College as a guardian of medical ethics and etiquette, a volume might be written. A hundred years ago the doctor was always satirised by all classes of writers as unscrupulous. Now that charge is only occasionally brought against him by the illiterate, who count for nothing in the long run. That this immense change has been effected is mainly due to the College. And here it is only fair, just reference having been made to the College Museum and Library, to mention the College Office. A long line of secretaries, from Okey Belfour to Mr. Trimmer and Mr. Cowell, have patiently and vigilantly guarded the surgical point of honour. If ever a black sheep has been driven out of the surgical flock it is the College Office that has weighed his demerits and impeached him in the first instance. And this not without deliberation, or, as it was once called, "prayer and fasting." On the other hand, if ever a practitioner has been wrongly accused of malpractice, or unprofessional conduct, it is the College Office that has been at the root of his rehabilitation.

To resume and to conclude—and with the thermometer at 87° it is as well to do so—the surgeon of 1900 is not as his far-off brother of 1800, and the College, in no small degree, has been responsible for the laudable and tremendous transformation. Mere literary men in England have no Academy at their head so drastic and salutary as the College to which surgeons can look up. The doctor in 1800 used occasionally to stipulate, when dealing with workhouse authorities, that he should not be required to treat fever cases. Fever, by the by, in the undrained London of the years prior to Sir John Simon's reforms, was a common cause of death among even the well-to-do. Now, to quote the sestet of an unpublished sonnet,

> "To-day skill'd Science runs where bullets hail,
> Or cholera's rife, for love of suffering man,—
> At the laboratory-table seeks
> Plague's grim bacillus, and, if need be, can
> Die as did Müller. Nor shall heroes fail:
> From Hunter on to Lister their fame speaks!"

VICTOR PLARR.

## ELECTRICAL POWER DISTRIBUTION.

IN a lecture on "Electricity as a Motive Power," delivered to the working men of Sheffield, August 23, 1879, the following question was asked: "And why not now? Why should not the mountain air that has given you workmen of Hallamshire in past times your sinew, your independence of character, blow over your grindstone again? Why should not division of labour be carried to its end, and power be brought to you instead of you to the power? Let us hope then that in the next century electricity may undo whatever harm steam may have done during the present, and that the future workmen of Sheffield, instead of breathing the necessarily impure air of crowded factories, may find himself again on the hill-side, but with electric energy laid on at his command."

The present year sees the dawn of the realisation of this idea of twenty-one years ago. For soon it will no longer be: "If," as I said on that occasion, "a workman could have transmitted to him, just at the time he might require it, a small amount of energy at, say, one halfpenny per hour per horse-power—which would be three or four times the actual cost of production with a very large steam engine—and if he could turn off the power like gas when he did not want it, how many of the smaller workmen of Sheffield would be glad to avail themselves of such a facility?"

To enable such a scheme to be carried out in this country, four Electric Power Distribution Bills have this year been brought before Parliament—one for the county of Durham, one for Tyneside, one for Lancashire, and one for South Wales. And in advocating their second reading on March 1, the President of the Board of Trade expressed the opinion that "the question which the House has to decide is a very important one, perhaps one of the most important ones that have come before the House by means of a private Bill for many years." For he pointed out that "the electrical enterprise of this country is in an exceedingly backward condition," and that:—"It may almost be said that there are villages in North America which are in possession of advantages in connection with electricity which some of our largest towns do not possess."

This opinion was shared by Sir James Kitson and the Committee of the House over which he presided. For from May 3 to well into this month, July, they sat deliberating as to whether, and under what conditions, permission should be given for electric energy to be distributed over nearly 3000 square miles of Great Britain.

A vast amount of evidence was taken regarding the effect on British industry, on the cost of producing manufactured products, and as to the growing up of new factories, and even of new trades, that might come into existence through a general distribution of electric energy. Employer after employer came forward and spoke of his individual need for electrical energy to work scattered tools in his factory, to ventilate and pump his mines, as well as to cut and haul his coal.

"Cheap power is the panacea for the evil effects of foreign competition" was urged again and again by the long stream of manufacturers who occupied the witness box for weeks. The advocates of this cheap power were marshalled in groups like bands of warriors, and, from the various classes of witnesses champions were selected who bombarded the Committee with proofs of the paramount importance of their cause, and overwhelmed the members when they struggled to grasp the arithmetic of "load factors," and begged to know how many Board of Trade units there might be in a horse-power.

At first we recognised many provincial dialects among the crowd in the Committee Room, but when it began to be realised that the inquiry would occupy more weeks than it was at first thought it would need days, the

Northumberland burr was left dominant, and remained so during the whole of May. Then a Lancashire wave rolled in, and it was not until the beginning of the fourth week in June that the "ll" and the "y" formed part of so many of the words that even counsel who had come through the Severn Tunnel to Westminster to plead their cause found some difficulty in pronouncing the names of persons and places.

But the advocates of the universal supply of "electricity in bulk" had not it all their own way, since opposed to them was a band of skirmishers who delivered well-planted criticisms aimed at exposing the grasping character of some of the projects and the desire—not even thinly concealed—of some of the promoters to crush out all small existing systems of electric distribution and to establish huge monopolies for purveying electric energy.

So that one had to moderate the enthusiasm called forth by the near prospect of electric energy being regarded as a public necessity, and therefore being generally distributed like water or gas, with the exercise of a cautious regard for the interests of those undertakers—to use the legal term—who had already been entrusted with spending the money of the ratepayers or of shareholders in establishing electric distribution systems in their own areas. For they contended that this proposal to supply the small and scattered manufacturers with very cheap electric power, which it was alleged would enable them to compete successfully with their more powerful rivals, could not be commercially realised, and that these power distribution schemes had for their object the catching of the popular vote and the passing of Bills which would enable their promoters to pick out those of the customers who were the plums among the consumers already supplied by means of the existing electrical undertakings.

For nine weeks the Committee listened to the arguments *pro* and *con.*, and the tolerance which they showed in patiently hearing questions asked by counsel which had been already asked in their absence and replied to by witnesses who were unaware that the same questions had been answered at length days before, showed how willing the members were to devote their time to a full understanding of the points at issue in order that they might be able to ultimately deliver a sound decision.

The articles of commerce, which we are accustomed to purchase may be divided into those that have weight and volume and those that have not, and it is generally in connection with the former that our system of weights and measures is employed—a pound of mutton, a yard of cloth, four ounces of letter carrying, a thousand cubic feet of gas, a mile of railway journey. But the advance of civilisation has gradually led us to regard as equally suitable for buying and selling other conveniences which it would be far more difficult to meter for the purpose of ascertaining whether we had received our fair supply. A year of police supervision, a length of street improvement, a winter of snow removal, a season of South African campaigning are considered as being furnished at a fair price only when the grumbling in connection with the supply is not too great and the articles in the *Times* are not too severe.

But there remains one commodity which, although it has neither weight, volume, nor linear dimension, can be metered with extreme accuracy, and the public demand for which is daily becoming greater and greater, and that is—energy. Hitherto the working of factories has been associated with water and coal, and either the factories have been built near the stream or in a coal region. When, however, such a site could not be conveniently found, then it has been the custom to carry at a dear rate a black, bulky, dirty substance by rail or water for miles to the factory, and, after strewing a certain portion of its dirt over the neighbourhood in the form of a descending cloud, to cart the remainder away as dusty ashes.

So accustomed are we to all this—so little does it strike us as incongruous that scuttles full of black lumps should be regularly brought into a drawing-room, no matter how valuable the pictures or rich the curtains and carpets, that we forget that our successors will look with more scorn on our customs than we do on those of our ancestors, seeing that, at least, their floor-coverings of rushes, intermingled with old bones and other refuse, could not be much injured by smoke or by dust.

Electric-lighting, electric-heating, electrically-driven machinery are all undoubtedly clean, but will the two latter pay as well as the former? On this point the evidence before the Committee of the House was somewhat conflicting. What, in fact, is the cost of carrying coal compared with the cost of electrically conveying the energy, or the "essence of the coal" as one of the counsel poetically termed it? Further, what is the saving produced by combining steam-engines, and working one very large engine instead of many small ones at different places?

Briefly, then, apart from all question of dirt, is it cheaper to burn the coal at the pit's mouth, and to convey the energy electrically to each of many machines situated within a radius of, say, ten miles from the electric generating centre, or to load the coal on railway trucks, carry it in different directions to many factories, unload, stoke the furnaces at many places, and distribute the energy from the many steam-engines by shafting, belting, rope-gearing, compressed air, or an electric current generated at the individual factory?

At first sight one would be inclined to answer that without doubt the electric driving of individual machines over an area of, at any rate, fifty square miles from a single centre must be the cheaper. For can we not employ quite thin electric mains and still have only a small percentage loss of energy in transmission, by using a very high electric pressure and sending through the mains a comparatively small current, whereas we have no means of compressing coal, so that not merely its volume, but also its weight and its cost of transport, can be greatly diminished for a given amount of coal-energy conveyed? No doubt; but Great Britain has its Board of Trade, and that body not unnaturally looks with disfavour on the overhead wires in Western America, which are maintained at so high an electric pressure that it is only the spitting and brush-discharge that occurs which prevent a higher pressure being employed. For that is how the commercial limit of 40,000 volts has been arrived at in the United States for overhead electric transmission of energy.

Eleven thousand volts is the highest potential difference that has hitherto been allowed—even for buried conductors—by our Board of Trade, and even that pressure has been employed in connection with only two systems of transmission, viz. the one from the London Electric Supply Company's generating station at Deptford to their transforming stations at Trafalgar Square, Bond Street, &c., and the other from the Metropolitan Electric Supply Company's new generating station at Willesden to their transforming stations at Amberley Road, Manchester Square, &c.

The promoters of the four Power Bills, therefore, do not contemplate using at the outset a higher pressure than 10,000 volts, or sending more than 1000 kilowatts—that is, 1340 horse-power—through a single underground cable. The evidence as to the cost of such a cable showed that it could be made and laid for something like 1400*l.* a mile; some of the witnesses said 1000*l.*, while others thought that was a "promoter's figure," since they had not succeeded in getting similar cables constructed and laid in trenches in their own districts under 1800*l.* a mile.

It is well known that the relatively high price of electric-lighting arises from the small fraction of the twenty-four hours during which there is any great demand for electric energy, so that it is necessary to fit up in an electric-light central station engines and dynamos which can develop something like ten times as much horse-power as would be necessary to deliver the same total amount of electric energy in the twenty-four hours if the demand were a steady one. This is expressed by saying that the "load factor" is 10 per cent. In one or two English towns the load factor is actually as low as 6, and in very few cases is it higher than 12 per cent.

Now it was urged that if an electric generating station, instead of supplying current simply for electrically lighting a single town, were to supply electric energy for all sorts of purposes throughout a large district, the load factor would be very much higher, and the cost of production would be proportionately diminished. For example, with electric tramway work the load factor is about 40 per cent., that is to say, about 40 per cent. as much electric energy is used by the cars as could be produced by all the engines and dynamos in the tramway station if they were working at full load continuously day and night. With factories again, it was estimated that a load factor of some 30 per cent. might be obtained. Hence it was urged that one of these large electric power stations might rely on a load factor of about 25 per cent.

With this load factor of 25 per cent., it was estimated by Mr. Ferranti, for example, that if a generating station were erected in the coal-fields at a spot with a good supply of water for condensing the steam, and if the plant capacity were about 16,000 horse-power—of which 4000 would be kept as a reserve—the entire cost of generating a Board of Trade unit would be about 0·44*d*., and the cost of transmitting it 0·2*d*. So that it could be sold to the consumer at 1¼*d*., and a good business done, as contrasted with the 4*d*. or 6*d*. per unit now charged to private consumers in English towns.

As opposed to this, it was urged by central station engineers and others that this supposed great economy to be obtained by erecting electric generating stations at the pit's mouth and transmitting the energy electrically through considerable lengths of buried conductors was imaginary; that in towns like Manchester, Liverpool, Southport, Bolton, Cardiff, Newport, &c., electric energy for driving machinery was already offered to the public at as low a price as the promoters of these Bills proposed to offer it, that the fraction of the cost of delivering a Board of Trade unit which could be debited to the coal alone was small, and that the proportion arising from the mere cost of carrying the coal was still smaller.

As a matter of fact, although the average prices obtained for private electric lighting are 3·49*d*., 4·04*d*., 4·10*d*., 4·68*d*., 4·69*d*., 5·29*d*. per Board of Trade unit by the Corporations of Manchester, Bolton, Southport, Cardiff, Liverpool and Newport respectively, any person in Manchester who desires to run an electromotor, no matter how small it may be, during the whole of the ordinary factory hours, only pays now 1¼*d*. a unit to the Corporation. In Bolton he is charged 1·35*d*. if he takes his full demand for 640 out of the possible 2184 hours in a quarter. Southport charges the Tramway Company 1¼d. per unit. Cardiff offers the unit at 2*d*. if 4000 units are taken per annum—which means a single motor of only 1 horse-power running for about eight hours a day for 300 days in the year. The Liverpool Tramway Company pays the Corporation only 0·9*d*. per unit; while in Newport, 1⅓*d*. is the price charged if more than 3000 units per quarter are taken.

The sweeping accusations, therefore, that some of the witnesses levelled against the local authorities of supineness, indifference to the public needs, &c., were hardly borne out; while such evidence as that of the electrical engineer of Southport, that the carriage of coal to that borough increased the cost of the unit by only one-twelfth of a penny, and of the electrical engineer of Manchester, that the charge for interest on the cost of *buried* cables added 0·49d. to the value of the Board of Trade unit if it were transmitted twenty-five miles, whereas the cost of conveying the equivalent amount of fuel by railway over the same distance only increased the value of a Board of Trade unit of energy by 0·059*d*., that is by only about one-eighth of the former, combined with the evidence that on the Continent and in America cheap *overhead* wire transmission was allowed, and therefore was generally adopted, led the Committee to realise the following, viz.:—that while the assent to the new proposals might confer a great boon on collieries and manufactories in scattered districts, a great wrong might be inflicted if safeguards were not introduced to prevent the introduction of the new electric schemes crippling the natural development of those systems of electric distribution which at present existed in this country, and which had been brought to their present condition by the expenditure of about 40 millions sterling during the past ten years.

In addition to the opposition to all the four Bills, made by private companies who had already obtained provisional orders to supply electrical energy, and by local authorities, some of whom had, and some of whom had not, obtained statutory powers to act as electrical suppliers, two of the Bills, viz. the Durham and the Tyneside, opposed one another. For whereas in the Durham Bill the district up to and including the south side of the Tyne is scheduled, in the other Bill both sides of the Tyne, from the mouth to Ryton, are included.

The promoters of the Tyneside Bill maintained that the *two* sides of the Tyne together naturally formed a *single* supply district, and that a company which had powers to supply the manufacturers on *both* sides with electric energy could do so more economically than if it was confined to the land along the north shore only. But they added that they had no objection to competition on the part of the proposed Durham Company or of any one else.

The Durham promoters urged that they were including in their area a lean portion towards the south of the county of Durham, which they could only undertake to supply if they were given the possession of the south bank of the Tyne undisturbed by competition on the part of the proposed Tyneside Company. It was also alleged that, although these various Bills passed their second reading because the President of the Board of Trade had stated that he had "an assurance from the promoters to the effect that they will undertake to agree to an amendment in Committee which would make it perfectly clear that they do not ask for the power to distribute even in bulk without the consent of the local authority," the Tyneside scheme really aimed at obtaining *private* way-leaves, and by skipping about the district by means of *overhead* wires to supply even private customers in retail without asking for the consent of any local authority. And it was pointed out that the assent to such a proposal would be manifestly unjust in view of the fact that those who were already supplying under "provisional orders," or who might obtain such orders, were compelled under the terms of such an order to supply every one within a certain "compulsory area" within a limited time, as well as being subject to comply with other obligations.

Serious opposition to the Tyneside Bill was also raised by the Newcastle Electric Supply Company. This is the company which for some years has been supplying electric current to the east of the district of Newcastle-upon-Tyne, but which, by arrangement with various local authorities and with the Walker and Wallsend Union Gas Company—which obtained last year a Provisional Order for supplying electric energy to the districts of Wallsend and Willington Quay—has this session been promoting a Bill for distributing electric energy throughout a considerable area along the north of the Tyne to the east of Newcastle.

Between the proposed Tyneside Company and the existing Newcastle-on-Tyne Company a battle royal raged in the Committee Room, not merely because the area proposed by the one included that proposed by the other, but because a certain site on the Tyne bank was scheduled by both companies as the land on which they proposed to erect a generating station.

The advocates of the Tyneside Company, led by Lord Kelvin, asked, in fact, for authority to erect three generating stations—the one just referred to, one immediately opposite on the south bank of the Tyne, and one on the same bank, but much further west.

The advocates of the Newcastle-on-Tyne scheme, on the other hand, pleaded that the first site should be left to them, and urged, not unreasonably, that if the Tyneside Company confined its attention solely to that small bit which lay on the north bank of the Tyne to the west of Newcastle, of the whole of the area it contemplated, it would have ample scope for the spending of its entire capital, viz. a million sterling.

Indeed, one of the grounds of opposition to all the four large schemes before this Committee was that, while enormous areas were scheduled in the Bills, throughout which it was proposed to distribute electric energy, the capital asked for by any one of these companies was only a few hundred thousand pounds, or not more than a million, even when, as in the case of the Tyneside Bill, it was increased to that amount while the Bill was before the Committee. To this the advocates of these four Bills replied that the amounts put down for capital, even as increased during the progress of the Bills through Committee, were only intended to enable a start to be made, and that after a few years the companies would necessarily come to Parliament again for a large increase in capital. Further, that while it was proposed to start with erecting in each of the four districts a single 10,000 horse-power electric generating station, in a few years 50,000 or more horse-power would have to be electrically delivered in each of these districts if the Bills passed.

Excepting the Newcastle-on-Tyne Bill, which came before another Committee, the Lancashire Bill was the most moderate. On the other hand, the South Wales Bill was the most grasping, for it was the only one which professedly aimed at obtaining powers to invade a town and break up its streets without the consent and even against the wish of the local authority if the person whom the company aimed at supplying with electric energy was a "wholesale customer." And such a customer was defined in the Bill as one who was prepared to take 20,000 units a year.

Those who drafted this Bill no doubt were under the impression that there were very few people in the 1050 square miles of the counties of Glamorgan and Monmouth covered by this Bill who at present took more than 20,000 units a year. And no doubt that was the case, for only some six could be cited by those who represented the Corporations of Cardiff and Newport. But hitherto it has been almost exclusively for lighting that people in these boroughs have taken electric energy, and when from the electric supply systems of these Corporations, or from the mains of some outside company—should such a company gain access—manufacturers begin to receive current for working electro-motors, then a 20,000 unit customer would only pay 83*l.* 6*s.* 7*d.* a year for his energy, at 1*d.* a unit, and therefore in no sense could he come under the category of "wholesale."

In fact, when the promoters of the South Wales Bill realised that even a 3 horse-power motor running continuously day and night—in connection, for example, with a blast furnace—would consume 20,000 units a year, and that a 9 horse-power motor working ten hours a day for 300 days in the year would require the same amount of electric energy, they saw that their "wholesale customer" would have to be thrown overboard.

In despair, however, the promoters still clung to the reed that a local authority could not if it would, and should not if it could, erect plant for supplying factories with electric energy on the large scale contemplated by these Electric Power Distribution Companies, and they urged that the ratepayers' money ought not to be used for speculative purposes, forgetful apparently that, even when a local authority has bought up an electric supply undertaking at twice the sum that it cost the private company to erect it, the rates have been ultimately relieved in consequence of the purchase, and the ratepayers therefore benefited by the local authority becoming a purveyor of electric energy.

Ultimately, on Wednesday, June 27, the chairman, Sir James Kitson, who it is important to remember is not merely an M.P., but what is far more important the head of a great manufacturing firm, a director of a great railway, and the ex-Mayor of a great city, made the following most excellent declaration:—

"A local authority which undertakes and is prepared to give a full and ample supply of electrical energy for all purposes to consumers within its district ought not, without its consent, to be required to give facilities for the supply, within its district, of electrical energy by other undertakers. But if a local authority is unable or unwilling to provide on reasonable terms and within a reasonable time a full and adequate supply of electrical energy for any purpose to any company or person applying for the same within its district, such company or person should be at liberty, after notice to the local authority, to obtain their supply from other authorised undertakers, and the local authority should be required to give all necessary facilities for this purpose. Any difficulty arising out of the above questions should be subject to arbitration as provided by the general Acts."

Doubtless this decision did not please all; but how acceptable was it to those who, like myself, have been hungering for the realisation of our dream of twenty-one years ago—"power brought to the workman, not the workman to the power"—but who have seen with apprehension the growth of obstacles nourished by England's spirit of masterly inactivity and by its not unnatural, nor wholly unwise, veneration of vested interests.

For now local authorities are put on their metal. If you realise, says Sir James Kitson's Committee, what are your duties in providing all your people with "an ample supply of electrical energy for all purposes," we will be no parties to any hindrance through competition being put in your way. But if your district be one in which bumbledon reigns supreme, then our declaration is that no municipal barrier shall be left standing to oppose the free entrance of those who come with offers of cheap electric energy.

Next, on Thursday, June 28, the formal statement was made by the Chairman:—"that the preamble of the South Wales Electrical Supply Bill is proved, also that the preamble of the Durham (County of) Electric Power Supply Bill is proved; and the preamble of the Tyneside Electric Power Bill is not proved to the satisfaction of the Committee, and that the preamble of the Lancashire Electric Power Bill is proved to the satisfaction of the Committee." Then followed the lengthy process of drafting the clauses, and finally, on July 16, these three Bills, of which the preambles had been reported by the Committee as proved, were read a third time in the House.

On the following day, the North Metropolitan Electric

Power Supply Bill, which asks for authority to supply electric energy over a smaller region, consisting of the districts of Hornsey, Hendon, Barnet, St. Albans, Hatfield, Hertford, Ware, &c., was, after being considered by another Committee of the House of Commons, read for a third time, and finally, on Tuesday, July 24, the Newcastle-on-Tyne Electric Supply Companies scheme already referred to in this article received the sanction of a Committee of the House of Lords.

The era of Electrical Power Distribution on a vast scale in our country has, therefore, begun.

W. E. AYRTON.

## THE DAILY WEATHER REPORT OF THE METEOROLOGICAL OFFICE.

THE Meteorological Council has made provisional arrangements for the sale of single copies of the Daily Weather Report at a penny each from the first of August next. The copies will be on sale from about 3 o'clock of the afternoon of the day of issue at the Meteorological Office and at the railway bookstalls of the following terminal railway stations in London: Victoria (S. E. & C. and L. B. & S. C.), Charing Cross, St. Pancras, King's Cross and Euston. Hitherto the issue of the reports has been confined to certain public offices and institutions, and to annual or quarterly subscribers. The distribution has been by hand or by book-post. The area within which delivery can be effected on the day of issue is necessarily very limited, and it is hoped that the facilities afforded by the new arrangement may bring the information which the reports contain within the reach of some of those interested in the subject who live outside the present limits of delivery on the day of issue. If the provisional arrangement should make it apparent that there is any public demand for the accommodation, efforts will be made to continue and extend it.

From the same date some modifications will be introduced into the form of the Report. The morning and evening observations of the telegraphic reporting stations will appear on the first page as usual, but the two charts on the second page, representing the morning distribution of pressure, wind and sea, and of temperature and weather respectively, will be supplemented by three smaller charts. One will represent the barometric distribution over the whole of Europe at 8 a.m. of the preceding day in order that the general atmospheric changes may be more readily traced. Another will represent mean monthly or bi-monthly morning isotherms for the British Isles, so that the distribution of temperature for the day may be easily compared with the normal distribution for the season as estimated for a period of twenty-five years. The third will represent the distribution of mean maximum temperature estimated in a similar manner.

There will also be several changes on the fourth page of the Report. Instead of "General Remarks on the Weather over Europe" there will be a table giving the latest information in the possession of the Office as to maximum and minimum temperature, rainfall, and weather at selected stations on the Continent and elsewhere which are beyond the area represented by the telegraphic reports. The selection of the stations will be mainly determined by the current interests of travellers, and will be varied from time to time according to the information available.

The information as to the weather in the British Islands will also be supplemented by data as to sunshine for the preceding day from a number of stations which will report by post, and it is intended, in course of time, to replace "yesterday's 2 p.m. reports" by postal reports of maximum and minimum temperature and rainfall for a number of inland stations which are expected to prove a useful addition to the telegraphic reports of the first page.

For convenience of reference a small supplemental table will give the Greenwich time of sunrise, noon, and sunset for four selected stations in the British Isles, so that the variation in the duration of daylight and the standard times of local noon for any locality may be ascertained.

W. N. SHAW.

## THE BRADFORD MEETING OF THE BRITISH ASSOCIATION.

THE local arrangements for the Bradford meeting of the British Association in September next are now rapidly approaching completion. The railway companies have agreed to give the usual special facilities, both to visitors who come to Bradford from long distances, and to members resident in Yorkshire who travel to and fro every day. Those persons who attend the meeting can obtain a return ticket from nearly all the railway companies at a fare and a quarter, provided they present to the booking-clerk a certificate, which can be obtained on application to the local office at 5, Forster Square. Any Members or Associates visiting Bradford day by day, and staying in places within fifty miles of the city, can obtain return tickets at the single fare on presenting their card of membership to the booking-clerk in Bradford. The following railway companies have entered into this arrangement:—the Caledonian, the Great Eastern, the Great Central, the Great Northern, the Great Western, Lancs. and Yorks., London, Brighton and South Coast, London and North Western, London and South Western, Midland, North British, North Eastern, South Eastern, Chatham and Dover, and the other companies belonging to the Associated Railways.

The local programme is now in the press, and will be issued within the next fortnight to the Members and Associates who have notified their intention of being present. The following items, however, will give a brief summary of the information contained in it:—

### GENERAL PROGRAMME.

*Wednesday, September* 5.—4 p.m.: Meeting of General Committee at the Town Hall; 8.30 p.m.: the President's Address in St. George's Hall.

*Thursday, September* 6.—3.30 p.m.: Reception at the Technical College (Textile Exhibition); 8.30 p.m.: the Mayor's Conversazione in St. George's Hall.

*Friday, September* 7.—8.30 p.m.: Lecture in St. George's Hall by Prof. Gotch, F.R.S., on "Animal Electricity"; 9.30 p.m.: Smoking Concert in the Technical College in honour of the President.

*Saturday, September* 8.—Excursions (half-day); 8 p.m.: Artisans' Lecture in St. George's Hall, by Prof. Silvanus Thompson, F.R.S.

*Sunday, September* 9.—10.30 a.m.: Sermon by the Bishop of Ripon in the Parish Church.

*Monday, September* 10.—3.30 p.m.: Corporation Garden Party in Lister Park; 8.30 p.m.: Lecture in St. George's Hall by Prof. W. Stroud, D.Sc., on "Range Finders."

*Tuesday, September* 11.—8.30 p.m.: Corporation Soirée in St. George's Hall.

*Wednesday, September* 12.—3.30 p.m.: Private Garden Parties; 8 p.m.: Full-Dress Concert in St. George's Hall (Festival Choral Society; Permanent Orchestra; conductor, Mr. F. H. Cowen; Miss Ella Russell).

*Thursday, September* 13.—Excursions (whole day).

The conferences of delegates of corresponding societies will be held on Thursday, September 6, and Tuesday, September 11, at 3 p.m., at the Reception Rooms.

The Reception Room at the Grammar School will be opened on Monday, September 3, at 2 p.m. to 6 p.m., and on the following week-days at 8 a.m. to 6 p.m. On Sunday, September 9, the Reception Rooms will be open from 9 to 10.30 a.m., and from 3 to 5 p.m.

The temporary Museum in connection with the Sections is this year being made a special feature, more particularly in regard to Geology, Botany and Zoology. Joint meetings are being held, on certain days, of the Geological and Botanical Sections, to take up the subject of Carboniferous fossils, and it is proposed to form a collection of fossils found in the neighbourhood to illustrate the papers as much as possible; and also to display photographs bearing on the subject, taken from the Geological Society's collection in London. These exhibits will form the nucleus of the Museum, but there will also be other collections bearing on the main subjects dealt with by some of the other Sections. At the Municipal Technical College there will be an Exhibition during the week illustrative of the staple trades of the district; visitors will pass from room to room, and will see the gradual development, through innumerable processes, of the most elaborate fabrics from the unwashed fleeces. On Thursday afternoon, September 6, the Exhibition will be opened by Mr. W. E. B. Priestley, the chairman of the College, and a Reception held, to which all visitors to the meeting will be invited.

The preparations for the Excursions and Garden-parties are nearly complete, and full details will be given in the next article.

RAMSDEN BACCHUS.

## NOTES.

PROF. R. LIPSCHITZ, professor of mathematics in the University of Bonn, has been elected a correspondant in the section of geometry of the Paris Academy of Sciences.

LORD KELVIN has been elected Master of the Worshipful Company of Clothworkers for the year 1900–1901.

SIR JOHN EVANS, K.C.B., F.R.S., has been elected chairman of the Society of Arts for the ensuing year.

MR. GRANT-OGILVIE, principal of the Heriot-Watt College, has been appointed director of the Museum of Science and Art, Edinburgh.

THE sixty-eighth annual meeting of the British Medical Association will be held at Ipswich during next week, commencing on Tuesday.

DR. M. ARMAND RUFFER, president of the sanitary, maritime, and quarantine board of Egypt, has recieved from His Majesty the Sultan of Turkey the Order and Insignia of the Medjidjieh of the Second Class.

A CONFERENCE on the housing of the working classes, under the auspices of the Sanitary Institute, will be held on July 30 and 31, in the lecture-room of the Royal Medical and Chirurgical Society. In connection with the conference an exhibition of models and plans will be held in the Parkes Museum.

IT is stated in the *Engineer* that of the fifty-five ships taking part in the naval manœuvres this year, the *Adrienne*, *Camperdown*, *Jaseur*, besides some others, are specially fitted for wireless telegraphy. The *Majestic* and the *Diadem* have also been fitted. Torpedo officers have charge of the installation in each case.

THE thirty-seventh annual meeting of the British Pharmaceutical Conference was opened in London on Monday, under the presidency of Mr. E. M. Holmes. An attractive programme containing illustrations of the house of the Pharmaceutical Society where the meetings will be held, the president, and places to be visited, appears as a supplement to the current number of the *Pharmaceutical Journal*.

WE learn from the *British Medical Journal* that the Madras Government has passed an order sanctioning the excess expenditure over the original grant of 600 rupees incurred by Capt. R. H. Elliott in connection with the prosecution of his researches into the properties of snake venom, and has made him an additional grant of 200 rupees to cover the cost of further experiments. The Surgeon-General has been requested to report if Capt. Elliott's services will be available for special duty at the end of September when his tour of service terminates.

PROF. HENRY F. OSBORN has been appointed to succeed the late Prof. O. C. Marsh as palæontologist in the United States Geological Survey. Prof. Osborn's special field of work will be to take charge of the vertebrate palæontology of the survey, especially with reference to the completion of the monographs for which the illustrations were prepared under the direction of Prof. Marsh. Prof. Osborn graduated from Princeton in 1877, and was professor of comparative anatomy there until 1890. He was appointed Da Costa Professor of Zoology at Columbia University in 1891, and curator of vertebrate palæontology at the American Museum of Natural History, New York. He is a member of the National Academy of Sciences and other scientific bodies, and is the author of numerous papers and memoirs on fossil mammals and reptiles.

THE seventy-second annual meeting of the German Association of Naturalists and Physicians will be opened at Aachen on Monday, September 17. At the first general meeting, the advances of natural knowledge and medicine during the present century will be surveyed. Prof. van 't Hoff will review the progress of inorganic science; Prof. O. Hertwig will discourse on the development of biology; Prof. B. Naunyn will deal with internal medicine, including bacteriology of hygiene; and Prof. H. Chiari will speak on pathological anatomy in relation to external medicines. At the second general meeting, to be held on September 31, several scientific subjects of current interest will be dealt with. Prof. J. Wolff will speak on the correlation between form and function of individual structures of organisms; Prof. E. v. Drygalski will describe the plan and purpose of the German Antarctic expedition; Prof. D. Hansemann will discourse upon cell-problems and their significance in the scientific foundation of the treatment of disease; and Prof. Holzaphel will take as his subject the development of German coal-measures. On September 19, the naturalists and physicians will meet in separate groups. The questions to be brought before the former group include the circulation of nitrogen in the organic world, by Prof. M. W. Beyerink; the latest investigations upon steel, by Prof. E. F. Dürre; and language and technical teaching from a scientific standpoint, by Prof. Pietzker. The chief subject to be discussed in the medical section is the neuron theory in its anatomical, physiological and pathological aspects, by Profs. Verworn and Nissl. The remainder of the meetings will be held in the various sections of the Association, and as more than three hundred communications will be made, there will be no lack of subjects for discussion. In connection with the meeting, an exhibition of physical, chemical, and medical preparations and apparatus will be held.

IN the course of his presidential address, delivered to the Society of Chemical Industry on July 18, Prof. Chandler referred to some of the work of American chemists, and the development of chemical processes of manufacture. Many important investigations in agricultural chemistry have been conducted by the chemical division of the United States Department of Agriculture, among them being the practical determination of the number and activity of the nitrifying organisms in soil, the influence of a soil rich in nitrogen on the nitrogen content of a crop, the manufacture of sugar from the sorghum plant, and the comparative study of typical soils of the United

States. Of agricultural experiment stations there are now 59, and the 148 chemists connected with them have done a large amount of original investigation in subjects more or less closely allied to agricultural and physiological chemistry. Prof. Chandler gave a comprehensive account of the chemical industries. In particular he referred to the progress made in electro-chemistry, and described the methods now adopted for the reduction of aluminium at Niagara, and also for the manufacture of carborundum and artificial graphite. Speaking of water-gas, he described the opposition against its introduction for illuminating purposes. The question came before the Health Department of New York, and, after careful investigation, the department decided that the gas was such an improvement in quality and price, while the increased danger as compared with that from old-fashioned coal-gas was so slight, that it was not wise to interfere with it. The water-gas industry has now taken almost complete possession of the whole country. There are at least 500 gas companies using water-gas wholly or in part, and it is estimated that in 1899 three-quarters of the entire consumption, or 52,500 million cubic feet, consisted of carburetted water-gas. At the close of the address the Society's medal, which is awarded not oftener than every two years, was presented to Dr. Edward Schunck, F.R.S., in recognition of his classical investigations on natural colouring matters and other researches in connection with technical chemistry.

WE learn from the *Times* that the Select Committee to which the Sea Fisheries Bill was referred, presented a special report to the House of Commons on Thursday last expressing the view that it would not be expedient to pass the measure into law without further inquiry and investigation. The committee regards it as proved beyond the possibility of dispute that there is a very great and serious diminution of the fish supply, that the ancient fishing grounds are much depleted, and that in default of a remedy the consequences to the fishing industry and the fish supply will at no very distant future be disastrous. The prohibition of the taking and killing of such fish is described as practically impossible without prohibiting trawling altogether. As regards the prohibition of fishing within certain areas where small fish more particularly abound, the Committee thinks that it is established that there are certain well-known areas in the North Sea where undersized small and young fish congregate, and that to prevent fishing in such areas would be of great value. It is pointed out, however, that such a result could not be obtained without joint international action among the Powers bordering the North Sea, and that the difficulties of such international action and the policing necessarily ancillary thereto are obvious. In conclusion, the Committee considers that no effort ought to be spared—first, to arrange for international treatment of the subject generally, and especially for regulation of the North Sea area; and, secondly, to provide for the adequate equipment of the Government department in charge of the subject, so that it may effectively pursue scientific investigation, and ascertain with sufficiency and precision what has been done in the way of scientific research or in the matter of practical legislation by other inquirers and by other countries.

MR. E. H. L. SCHWARZ sends us from Cape Town some interesting remarks upon the snake-stone, *apropos* of the facts stated by Mr. Hervey in NATURE of May 24 (p. 79) as to the use of a stone by the Malays as a remedy for poisonous bites. Snake-stones are fairly common in South Africa, and are described as white, porous stones, which, when applied to the place where the snake has bitten a person, adhere till all the poison is drawn out into them, after which they are placed in milk, which in turn draws the poison from the stones, and renders them again fit for use. The farmers firmly believe they are taken from the head of a snake. It is suggested that snake-stones are made of pumice. To the uneducated, the structure of pumice has a close resemblance to that of bone, and this may possibly explain the popular delusion that snake-stones are made of bone. Mr. Schwarz thinks that the black colour of the stone, described by Mr. Hervey, may have been due to blood, or the stone may have been a black variety of pumice, for there is an instance of originally black pumice having been thrown up near the lighthouse on Cape Agulhas. The fact that the fable of the stone having been taken from the head of a snake is exactly the same in the Malay States as is prevalent in South Africa is interesting, though the Malay slaves which the early Dutch obtained from Batavia in exchange for quaggas, zebras, ivory, &c., may have carried the legend with them. It is not an uncommon custom in Germany for people to carry about with them nuggets of raw gold to draw out of their bodies all the more subtle evils, such as those produced by spirits and devils, while for the grosser evils they carry a potato. Is the snake-stone legend a derivative of these, or are they subsequent to the snake-stone?

MAGNETIC observations were made at several stations upon the day of the recent total solar eclipse (May 28), under the direction of Dr. L. A. Bauer. A brief statement of the results is given in *Terrestrial Magnetism*. Ten observers were engaged in the work, and eight complete series of observations were obtained—seven for declination and one for horizontal intensity. All the stations show a magnetic effect, which cannot be referred to any other cause than that of the eclipse, the principal effect occurring, like the fall in temperature, some minutes after time of totality. The effect is as though part of the night hours were interposed among the day hours, *e.g.* the declination at all of the stations having passed the morning elongation and approaching the mean value of day, is *increased* about 20″–40″ if the declination be east, and *decreased* if the declination be west; whereas, the horizontal intensity approaching at the time its minimum value for the day, is *increased* for a brief period after time of totality. The observations and results will be published in full in a *Bulletin* of the U.S. Coast and Geodetic Survey.

THE hot and dry spell which set in over a fortnight ago promises still to continue, and although the mid-day temperatures are not generally as high as they were on several days last week, they are far in excess of the average. There have been three days at Greenwich with the shade temperature above 90°, the highest reading as yet being 94° on July 16. The nights are also excessively warm, and on the night of July 22–23 the lowest reading at Greenwich was 67°·6, which is warmer than any night in July or August at Greenwich since August 8, 1846, when the thermometer did not fall below 68°. During the last week there have been five successive nights without the thermometer falling as low as 60°. There has been no rain in London for three weeks, and the same dry weather has been experienced generally in the south-east of England. The conditions have been less settled over the northern and western portions of our islands, where rain has fallen at frequent intervals and no very extreme temperatures have occurred.

FROM Dr. Oliver Lodge, F.R.S., we have received the reprint of a very suggestive lecture on "Modern Views of Matter," delivered before the Literary and Philosophical Society of Liverpool in March last. In it Dr. Lodge discusses the atomic theory, the ether, the conception of "electrons," and the still more recent hypothesis of the existence of "corpuscles."

ARRANGEMENTS have been made for six popular science lectures for young people, under the general title of "The World we Live On," to be delivered in Kensington Town

Hall during October and November next, and we have no doubt they will be as "instructive and entertaining" as the programme promises, for the lecturers are all experienced exponents of science. The quotation "Pupils trained on books, and books alone, are mere passive recipients of other people's ideas," which we notice on the programme, is not a very happy one; for popular audiences are, after all, only "passive recipients" of the ideas of the lecturer. Popular lectures upon scientific subjects direct attention to natural phenomena, and occasionally induce people to devote serious attention to some branch of science. On this account they are valuable, but there is of course a great difference between listening to an eloquent lecturer, or witnessing striking demonstrations, and actually carrying out the most elementary experiments.

WRITING to Sir Henry Burdett with reference to Mr. Craggs's endowment of a travelling scholarship in connection with the London School of Tropical Medicine, Mr. Chamberlain recently remarked:—"My experience at the Colonial Office daily impresses upon me the extreme importance of doing something to make life in our tropical colonies more healthy for those who are engaged there in the work of civilisation, whether as administrators, missionaries or traders. Science has already given us promise of good results in the near future, and nothing, I believe, can conduce more powerfully to a speedy and satisfactory result than such researches as those which Mr. Craggs has in contemplation. I hope that his munificent action may be followed by other benefactors, so that the work may be simultaneously pursued in different countries." The scholarship is one of 300*l*. per annum, tenable for three years, and is for research in tropical disease. The first scholar is now attached to an expedition which is engaged in attempting to give practical application to the theory of the inoculation of the human being with the malaria parasite through the medium of the mosquito. The expedition has been equipped by the Colonial Office and is now stationed in one of the most malarious districts of the Roman Campagna. When this experiment is completed, at the expiration of six months, the scholar will proceed to the West Indies, thence to the West Coast and probably to the interior of Africa.

THE fourteenth volume (for the year 1898) of the *Analele* of the Meteorological Institute of Roumania has just been published Besides the usual tables, it contains several important memoirs. M. St. Murat compares the magnetic instruments of the Institute with those of the Observatory of Parc St. Maur, and describes the observations made during 1898. The director, Dr. Hepites, studies the climatology of Braila and of the Roumanian littoral of the Black Sea, the distribution of rainfall in Roumania during 1898 (this paper being illustrated by a series of monthly maps), and the earthquakes during the same year. Brief accounts are given of eleven shocks, all of them of very slight intensity.

IT appears from Part ii. of the Eighteenth Annual Report of the Fishery Board for Scotland that the salmon fishery for 1899 turned out considerably below the average of recent years. It is true that the weight of salmon forwarded by rail and steamship during the year was slightly in excess of that carried in 1898, but it was still 638 tons below the average; and such slight improvement as took place is attributed to the large run of grilse which occurred during the summer. Adult fish seem to have been comparatively scarce. As the inspector remarks, it is absolutely essential to the continuance of the Scottish salmon fisheries that a stock of breeding fish sufficient to counterbalance the loss caused by fishing, by the salmon's natural enemies and by disease, must be maintained by some means or other. It is satisfactory to learn that some proprietors have established hatching-stations in order to artificially increase this supply. The inspector is, however, of opinion "that if the present catching power continues to be developed, a very great increase in the number and in the capacity of hatcheries will be necessary to produce noticeable results." In artificially augmenting the stock of salmon we must necessarily be prepared to compete with a vast mortality.

AMONG several papers interesting to entomologists in the June number of the *Agricultural Gazette of New South Wales*, reference may be made to one by Mr. W. W. Froggatt, the Government entomologist, on insects living in figs. The interiors of young wild figs in all countries swarm with minute plant-feeding Hymenoptera of the family Chalcidæ. The males and females of these minute insects differ from one another in colour, size and shape; but the peculiar feature of the group is that, instead of the females being degraded into a wingless condition, it is the males that are devoid of wings, while they are also frequently blind, with abnormally short legs and aborted antennæ, A new Australian species is described and figured.

IN the *Victorian Naturalist* for June, Mr. Robert Hall gives an interesting account of the nesting habits of one of the Australian diamond-birds (*Pardalotus assimilis*). In common with some of their kindred, these birds make their nests at the end of a tunnel drilled by themselves in a bank. "The nest is made to fit in a cavity with a domed ceiling, excavated in the hard subsoil at the end of the tunnel. This tunnel is ten inches long, and is drilled with a slight upward tendency, as is usual in most ground-boring birds. The nest entrance is two feet below the surface of the ground, and in a creek-bank some nine feet above a stream." Both sexes take part in the drilling operations, one excavating while the other removes the rubbish, but it seems that the task of incubation falls to the share of the male.

IN the June issue of the *Johns Hopkins University Circulars* will be found an important communication by Mr. L. E. Griffin on the arterial circulation in the nautilus.

WE learn from the *Bulletin* of the New York Botanic Garden that the herbarium has acquired during the year specimens to the number of 70,000, and that over 4000 species and varieties of plants, belonging to 172 families and 1057 genera, are under cultivation in the Garden.

WE have received Supplement ix. to the *Journal of Reading College*, consisting of the sixth annual report on field experiments (for 1899), viz.:—field experiments in Dorset, Berkshire, Oxfordshire and Hampshire; spraying experiments on charlock; trials with sugar-beet; the manuring of crops; and notes on manures.

CONTRIBUTIONS from the Gray Herbarium of Harvard University, New Series No. 19, consists of a synopsis of the Mexican and Central American species of *Salvia*; a revision of the Mexican and Central American *Solanums* of the sub-section *Torvaria*; and some undescribed Mexican plants (chiefly Labiatæ and Solanaceæ), all by Mr. M. L. Fernald.

HERR PAUL SINTENIS announces that he is undertaking a botanical exploration of the mountain region on the confines of Turkestan and Persia, of the flora of which district very little is at present known. The expedition will probably extend through the present year. Application for sets of the plants collected should be made to Herr Baurath J. Freyn, Smichow-Prague.

THE Agricultural and Mechanical College of Texas, judging from the annual "Catalogue" for the session 1899–1900, is a well-appointed and flourishing institution. Full information as to the various departments of the college, courses of study, &c., is to be found in the "Catalogue," which also contains many full-page illustrations of the college buildings, interiors of the laboratories, &c.

THE *Journal* of the Straits branch of the Royal Asiatic Society for January, 1900, contains, *inter alia*, an important contribution by Mr. H. N. Ridley on the flora of Singapore. The district is a rich one, something like 1900 flowering plants, and 130 ferns being recorded. Mr. Ridley opens with an interesting introduction, in which he gives a sketch of the factors which determine or modify the vegetation. He also describes some interesting phenological facts, and finally gives a sketch of the history of the botanical work in the Island. The chief space is, of course, devoted to an enumeration of the plants, but it contains short notes respecting the more striking individual species.

THE revised edition of "First Records of British Flowering Plants," by Mr. W. A. Clarke, just published by Messrs. West, Newman and Co., is full of extracts of interest to every one who finds pleasure in the study of the British flora. To members of Field Clubs and Natural History Societies the book is particularly valuable. It gives, in the form of extracts from printed botanical works published in Great Britain, the earliest notice of each distinct species of our native and naturalised plants, the last edition of the "London Catalogue" being taken as a basis. The volume thus provides a concise answer to the question which a naturalist often asks, viz. : "How long has this plant been known as British?" An interesting analysis of the "first records" is given at the end of the book. William Turner was the first to record the majority of our native plants. His works, ranging from 1538 to 1568, contain notices of 238 flowering plants, and may be considered the foundation of our British flora. From Lobel (1570, &c.), Mr. Clarke obtains eighty first records and from Gerard's famous Herball (1597), 182 species, so that about 500 species of British plants were known and described three hundred years ago. The book in which these and many other particulars are given is one which every naturalist should keep handy for reference.

THE *Proceedings* of the London Mathematical Society (vol. xxxi.), containing papers read from April to December of last year, have just been published by Mr. Francis Hodgson. The titles and brief abstracts of the papers have already appeared among our reports of societies.

THE Great Eastern Railway Company's "Tourist Guide to the Continent," edited by Mr. Percy Lindley, contains concise notes and numerous illustrations of interesting and easily accessible places in Holland, Belgium, Germany, Switzerland, Norway, Denmark and Sweden. The book is a useful travelling companion for Continental tourists, and is as matter-of-fact as most guide-books.

THE volume of *Proceedings* of the forty-eighth meeting of the American Association for the Advancement of Science, held at Columbus a year ago, has just been received. The presidential addresses, papers and abstracts cover a wide field of scientific work. A noteworthy feature is the series of portraits of former presidents of the Association, accompanying an address by Dr. Marcus Benjamin.

THE value of a well chosen set of inorganic chemical preparations as a part of a course of general chemistry is now generally acknowledged, although the number of elementary text-books dealing with this branch of the subject is comparatively small. The works of Prof. Erdmann, of Halle, in this field are well known, and the English translation of his "Introduction to Chemical Preparations" (Chapman and Hall) by Dr. F. L. Dunlap, the German edition of which has already been noticed in these columns, will be of great service to students in England and America.

THE seventh part of vol. ii. of the seventh edition of Fresenius's "Quantitative Chemical Analysis," translated from the revised sixth edition by Mr. C. E. Groves, F.R.S., has just been published by Messrs. J. and A. Churchill. This completes the new edition of the work, which has been revised throughout. The special part, dealing largely with applications of chemical analysis to industrial products and other technical matters, has been considerably extended, and many new analytical processes have been introduced. The last section of the work includes sixty exercises especially designed for teaching the theory and practice of quantitative chemical analysis. In addition, there is an appendix containing analytical notes and tables for the calculation of analyses. Practical chemists and teachers are thus now provided with a complete new edition of a standard work on analysis.

THE reaction discovered by Lubawin of the formation of $\alpha$-amino-acids by the interaction of ammonium cyanide and aldehydes, has been extended by Dr. W. Gulewitsch to ketones, and in the current number of the *Berichte* he describes the details of the preparation of $\alpha$-amino-isobutyric acid from acetone, the yield under favourable conditions being as high as 74 per cent. of the theoretical. The same number of the *Berichte* also contains a masterly investigation of the action of soda solution upon nitrosobenzene by Prof. Bamberger. No less than twelve substances have been isolated from the products of this extremely complex reaction, including azoxybenzene, nitrobenzene, aniline, *p*-nitrosophenol, *o*-amidophenol, *p*-amidophenol, hydrocyanic acid, ammonia, and four new acids, and there are still further products awaiting investigation.

THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. P. M. Thornton; a Rhesus Monkey (*Macacus rhesus*) from India, presented by Miss A. N. Ball; a Humboldt's Lagothrix (*Lagothrix humboldti*) from the Upper Amazons, presented by Mr. W. S. Churchill; two Masked Paradoxures (*Paradoxurus larvatus*) from China, presented by Mr. W. T. Lay; a Senegal Parrot (*Poeocephalus senegalus*) from West Africa, presented by Mr. S. Cordwell; two Chukar Partridges (*Caccabis chukar*) from North-west India, presented by Mr. Chas. E. Pitman; a Missel Thrush (*Turdus viscivorus*), European, presented by Mr. J. B. Williamson; a Common Cuckoo (*Cuculus canorus*), British, presented by Miss Lucy Holland; two Larger Hill Mynahs (*Gracula intermedia*) from Northern India, a Mauve-necked Cassowary (*Casuarius violicollis*) from the Aru Islands, a Clumsy Tortoise (*Testudo inepta*) from Mauritius, four Elephantine Tortoises (*Testudo elephantina*) from the Aldabra Islands, an Alligator Terrapin (*Chelydra serpentina*), six Blanding's Terrapins (*Emys blandingi*) from North America, deposited; a Guira Cuckoo (*Guira piririgua*) from Para, six Painted Frogs (*Discoglossus pictus*), South European, purchased.

## *OUR ASTRONOMICAL COLUMN.*

### ASTRONOMICAL OCCURRENCES IN AUGUST.

August 4. 11h. 55m. Minimum of Algol ($\beta$ Persei).
7. 8h. 43m. ,, ,, ,,
7. 5h. Conjunction of Mars and Neptune. (Mars 1° 27′ N.)
9. 11h. 34m. to 12h. 40m. Moon occults the star D.M. – 16°, 5609 (mag. 6).
11. Maximum of August meteoric shower. Perseids. (Radiant 45° + 57°).

| | | |
|---|---|---|
| Aug. | 12. | 16h. 10m. to 17h. 10m. Moon occults κ Piscium (mag. 5). |
| | 13. | 20h. Venus at greatest brilliancy. |
| | 15. | Venus. Illuminated portion of disc = 0·280. |
| | 15. | Mars. ,, ,, ,, = 0·932. |
| | 18. | Saturn. Outer minor axis of outer ring = 18″·35. |
| | 18. | 12h. 42m. to 13h. 24m. Moon occults ι Tauri (mag. 4·7). |
| | 18. | 14h. 47m. to 15h. 39m. Moon occults 105 Tauri (mag. 5·8). |
| | 19. | Mercury at greatest elongation (18° 32′ W.). |
| | 20. | 22h. Venus in conjunction with moon. (Venus 1° 49′ S.). |
| | 22. | Jupiter 26′ S. of β Scorpii. |
| | 23. | Expected return to perihelion of De Vico–Swift's comet (1844–1894). |
| | 27. | 10h. 26m. Minimum of Algol (β Persei). |

NEW VARIABLE IN HERCULIS.—Prof. W. Ceraski, of the Moscow Observatory, communicates to the *Astronomische Nachrichten* (Bd. 153, No. 3650) the discovery of a new variable by Mdme. Ceraski on photographs taken by M. S. Blajko. The star's position is as follows:—

| R.A. h. m. s. | Decl. ° ′ ″ | Epoch. |
|---|---|---|
| 18 30 54·8 ... | + 25 55 49 ... | (1855·0) |
| 18 32 44·1 ... | + 25 57 54 ... | (1900·0) |

The star is not found in the B.D. At maximum the star is slightly brighter than 9th magnitude, decreasing to a minimum of about 12th magnitude. At present its brightness is increasing.

NEW STAR IN AQUILA.—A telegram from Prof. Pickering, Cambridge, Mass., dated 1900 July 9, states that the *Nova* of the 8th magnitude found by Mrs. Fleming in April 1899 is now a nebula of 12 magnitude. Its position is

| R.A. h. m. s. | Decl. ° ′ |
|---|---|
| 19 15 16 ... | −0 19 |

A further statement is made in the *Astronomische Nachrichten* (Bd. 153, No. 3651) that the measures are from the photographs.

METEORITIC THEORY OF THE GEGENSCHEIN.—In the *Astronomical Journal*, No 483 (vol. xxi. pp. 17–21), Mr. F. R. Moulton puts forward a mathematical analysis of the conditions which would appertain if the *Gegenschein* were due to the presence of a more or less condensed region of meteorites. The idea of the problem appears to have been suggested by remarks of Prof. Barnard (who has made consistent observations of the phenomenon during the last sixteen years) to the author.

Discovered by Brorsen about the middle of this century, very few systematic observations are recorded until those of Barnard, who has made careful determinations both of its position and shape. He comes to the conclusion that it is always exactly opposite the sun, or as nearly so as can be determined. Other observers have stated varying positions, but in the case of so difficult an object it is advisable to consider the more systematic records as having greatest truth.

After citing the well-known reasons for considering that interplanetary space is densely occupied by meteoric particles, moving with widely varying velocities in all directions, he supposes that a great multitude will at any time be situated at the opposition point, and that a considerable proportion of these would be under such initial conditions as to remain there for some time. Then the meteors being very small compared with the earth, they are treated as infinitesimal bodies, disturbing neither the earth nor each other. He also neglects the eccentricity of the earth's orbit. Then referring the motion of one meteor to rectangular axes with the origin at the centre of gravity of the sun and the earth, he traces the conditions for stability for a certain time. Then by slightly varying the conditions, he finds the nature of the movement of the infinitesimal body with special reference to the circumstances under which it will make periodic oscillations around certain points. The result of successive integration suggests that meteors passing near one of these selected points with the assumed conditions of motion would be subject to forces directed nearly to this point, and would have a tendency to revolve round it. Although after a few revolutions they might escape, the average result would be a condensation with respect to space, if not with respect to time. The difficult point now to determine is whether a sufficient number would be captured to become visible. If the meteors are revolving round the sun at a distance of about 900,000 miles greater than the earth's mean distance, they will be moving slower than the earth, which will gradually overtake them in longitude. As they approach opposition they will be retarded and drawn in towards the sun, their motion being thereby accelerated. The net result of these actions will be to bring the meteors into the plane of the ecliptic, thus causing the condensation at opposition, and explaining the tendency to an oscillation in latitude which has been observed.

Instead of being exactly opposite the earth, the point of condensation will be nearly opposite the centre of gravity of the earth and moon, and consequently the *Gegenschein* should have a monthly oscillation in longitude of the nature indicated by the observations of Douglass, but much less in extent. The oscillation in latitude would, however, be monthly also, instead of yearly, as the observations tend to indicate.

A phenomenon, observed so far by Barnard alone, is the series of marked changes to which the *Gegenschein* is subjected in short periods of time, being large and round in September and the beginning of October, becoming slightly elongated by the 4th or 5th, very much elongated by the 10th or 11th, and showing merely as a swelling on the zodiacal band by the 18th. Although this is not directly explicable, the shape of the *Gegenschein* will depend on the thickness of the zodiacal disc of meteorites, and if the opposition point should pass through a dense portion of the swarm it is readily conceivable that a change of form would ensue. The distance of the opposition point works out at 930,240 miles from the earth. The period of oscillation would be 183·304 days. It is thus suggested as possible that meteors may move for long periods of time in the vicinity of the opposition point, in sufficient numbers to cause the faint glow of the *Gegenschein* by reflecting the light of the sun. Reference is finally made to a paper by M. Hugo Glydén in the *Bulletin Astronomique*, Tome 1, where similar views are enunciated.

METEOR OF JULY 17.—A bright meteor was seen in many parts of the north of England on the evening of Tuesday, July 17, shortly before nine o'clock. A few particulars concerning the phenomena are given by correspondents in the *Yorkshire Post*. An observer at Menston-in-Wharfedale saw the meteor at a point about N.N.W. from that place, and about forty degrees above the horizon. At Wiseton, Notts, it was seen at 8.47, and at Bramhope at 8.48. At Armley, a hissing noise was heard, and the meteor seen to disappear close by.

## *THE GREAT EARTHQUAKE OF JUNE* 12, 1897.

THE investigation of the great earthquake of June 12, 1897, being the most extensive of which there is historic record, has naturally led to important additions to our knowledge. A detailed report of this earthquake, by Mr. R. D. Oldham, has been published by the Indian Government,[1] and its investigation suggested a line of further research, the results of which have been published in the *Philosophical Transactions* of the Royal Society.[2] The principal results described in these bulky publications are here given in the form of an abstract.

The known extent of the principal seismic area was about 1,200,000 square miles, a figure which will surprise many after the statement that this was the greatest earthquake of which there is historic record. One of the results of this earthquake was, however, a re-examination of the records of the great Lisbon earthquake of 1755, which has shown that the statements regarding it, copied from one text-book to another, are grossly exaggerated. The statement that it was felt in the lead mines of Derbyshire is shown, by reference to the original record, to be an error, the shock that was felt being clearly an independent, local, though possibly sympathetic, shock. Apart from this, there is but one doubtful record of its having been felt so far north as England, though its effects were visible, both in England and in Holland, in disturbances of the water in ponds. The accounts of its having been felt in Iceland and America refer to the sea-waves, which may travel to regions far beyond the utmost limit at which the shock could be felt. Omitting these records, taking only those which refer to the sensible shock, and rounding off the seismic area to an elliptical form, it is found to cover not more than 1,000,000 square miles; while if the shock of June 12, 1897, is treated in a similar manner, we obtain a total seismic area of over 1,750,000 square miles.

---

[1] "Report on the great earthquake of June 12, 1897." By R. D. Oldham. *Memoirs* of the Geological Survey of India, vol. xxix. 1899, pp. xxx + 379 + xviii; 44 plates, 3 maps, 51 woodcuts in text.

[2] "On the propagation of earthquake motion to great distances." By R. D. Oldham. *Phil. Trans.*, Series A, 1900, pp. 135–174.

Owing to the paucity of good records, the course of the isoseists could not be traced in detail. The outermost isoseist was, however, determined with approximate accuracy for about half of its circumference. The seismic area presents a peculiarity in that there is a detached area in the alluvium about Ahmedabad over which the shock was felt, though it was unfelt over a tract of about one hundred miles separating this alluvial area from the furthest limit at which the shock was felt on rock. It is also reported to have been felt at Burhanpur, on the border of the Tapti valley alluvium, though it was felt nowhere else in the neighbourhood. Outside the area over which it was felt there are records, in India, of the passage of the earthquake wave as indicated by the swinging of lamps, &c.

Apart from the records in India, there is good evidence that it was felt in Italy; the observers at Catania, Leghorn and Spinea di Mestre all record having felt a slight shock at the exact time when the instruments throughout Italy recorded the advent of the first phase of the disturbance due to this earthquake. Had there been only a single record, it might have been attributed to a distinct local shock; but these three separate records, all agreeing with each other in time, and also with the advent of the first tremors, which, having a period of about ·5 second, might have been sensible, leaves little possibility of doubt that the Indian earthquake was actually felt. The observers are, however, to be complimented on their acuteness of observation.

The epifocal area is of a peculiar shape. Situated in Western Assam and North-eastern Bengal, it is bounded on the south by a straight line running about E.S.E. for some 200 miles; on the north it is bounded by a nearly symmetrical double sigmoid curve, the maximum breadth being not less than 50 miles, and possibly as much as twice this amount. Over the whole of this area of not less than 6000 square miles, the intensity of the shock was in excess of 10 degrees of the Rossi-Forel scale, and alterations of level have taken place; while for a year and more afterwards earthquake shocks—some severe, but most feeble and local—were very frequent. The changes of level were not only shown by faults, one of which was traced for a distance of over 12 miles, and had in places a measured throw of over 30 feet, and by differential changes of level, whereby streams were dammed up into lakelets, but also by a remeasurement of some of the triangles of the great Trigonometrical Survey. As the whole of the triangles reobserved lay within the epifocal area, it is not possible to say what amount of actual change has taken place; but changes of position of one hill relative to another were determined, which reach as much as 24 feet in a vertical, and 12 feet in a horizontal, direction.

The results of the triangulation, as published by the Trigonometrical Survey of India, indicate an increase in the horizontal distances between the stations; but in the geological report it is shown that this is probably due to a shortening, by compression, of that side which was assumed as an unaltered base-line. The true nature of the focus is regarded as a thrust plane, from which minor faults branched off, and in places appeared as such, while elsewhere they died out before reaching the surface and merely caused those changes of level which, where other circumstances were favourable, led to the formation of lakes. No less than thirty of these were observed, the largest having a length of 1½ miles and a breadth of ¾ mile, and the smallest a few yards across; the depth varied from 1 to over 20 feet.

Within this epifocal area the violence was everywhere great, though subject to great local increase in the neighbourhood of the fault planes which extended upwards to the surface. Not only were upright stones broken, but sound hardwood trees of a diameter of 6 to 7 inches were snapped across by the violence of the motion they were subjected to; no masonry building was left standing, and the hill sides were scarred by landslips. In many places it was noticed that stones lying on the ground had been projected into and through the air.

The acceleration necessary to cause the fracture of standing monoliths, or sound hardwood trees, must have been great—much greater than the measured accelerations, as determined by West's formula from overturned tombstones, which range up to 32 feet per sec. per sec. It is doubtful, however, whether West's formula is applicable to cases where the height of the overturned column is less than three or four times its diameter; in the earthquake of 1897 all the high accelerations were obtained in places where there must have been a large vertical component in the wave motion, and the overthrow of squat pillars is regarded as a modified form of projection. It is improbable that accelerations of over 6 feet per sec. per sec. can occur, except in the vicinity of the epicentre, where there is a considerable vertical component in the wave motion, and the excessive accelerations which have been supposed to have been measured in the case of other earthquakes must be regarded with suspicion.

Opportunity was taken to review the various formula for deducting the accleration and velocity of movement of the wave-particle; these have been all collected in an appendix and discussed. One result of the discussion is in a manner reactionary, for the one quantity which it was believed could be determined with real accuracy, the velocity as deduced from projection, is shown not to be due to wave motion at all. The velocities deduced from observed projections are shown to lead to impossible results if combined either with the deduced acclerations or with any conceivable amplitude or period, and the conclusion is come to that the projection of solid objects was due, not to molecular wave motion, but to a molar displacement of the ground, resulting in permanent changes of level.

Instances of the rotation of objects, both within and without the epicentre, were numerous. As many as possible of these were carefully measured to determine, not only the angular rotation, but also the direction and amount of displacement of the centre of gravity. From a careful examination of the data, it is shown that none of the attempts to explain rotation by simple rectilinear motion are in accordance with the observed facts, and that it is necessary to accept the explanation of vorticose motion. This vorticose motion does not, however, take the form of angular rotation as has been assumed by some investigators, but the whole ground either moves in a more or less circular track, or is subject to a more or less rectilinear to-and-fro motion, whose direction changes continually in azimuth.

Over a large alluvial area the river channels were narrowed, railway lines bent into sharp curves, and bridges compressed and destroyed, much as in the Japanese earthquake of 1891. This compression is shown to have been due, in all cases, to displacement of the superficial alluvium, and not to any general compression. Over this same alluvial area fissures and sand vents were opened in myriads. With regard to the fissures, it is shown that Mallet's explanation of their formation by unsupported masses of clay being thrown off from free surfaces by their own inertia is incomplete, and that they were formed in places where no such action could have taken place. It is suggested that in such cases the fissures were due to the visible surface undulations which were noticed by many observers. The sand vents were formed in such numbers that large areas were temporarily flooded by the volumes of water which issued from them with such force that it rose in solid columns to a height of 3 feet and more from the ground, while splashes and spouts are said to have reached 18 or 20 feet in height. It is noteworthy that in several cases these sand vents are said to have been formed *after* the passage of the shock, and flowed for a period of half an hour or, according to some, several hours. This is attributed to the settling of clay beds on to underlying quicksands, which supported the overlying beds as long as these were continuous, but would not do so after they had been broken up by the earthquake.

Earthquake sounds were very loud and conspicuous, but the data available do not allow of much advance in this difficult branch of seismology. In some cases explosive sounds of short duration were heard after the earthquake had passed, and the connection of these with the "Barisal guns," "mistpœffers," "marina" and other similar phenomena is discussed, all being regarded as probably in the main seismic.

The most important results obtained are probably those connected with the rate of propagation. Numerous time observations in India yield a time curve with double curvature like that of Schmidt's "hodograph," but the curvature is too slight to accord with it, and the true time curve is shown to be most probably a straight line indicating a uniform rate of propagation of 3·0 km. per sec. Turning from the observed rate of propagation of the sensible shock to the distant records, it is shown that the records of the Italian seismographs exhibit three principal phases of motion, after each of which there is a marked diminution of movement. The first of these gives an average rate of propagation of 9 6 km. per sec., the second of 5·6 km. per sec., and the third, the phase of long period undulation, accompanied by marked tilting of the ground, a rate of transmission of 3·0 km. per sec. The agreement of this with the observed rate of transmission of the sensible shock is held to indicate that both are due to a form of wave motion which was propagated at a uniform rate along the surface of the earth. The first two phases, it is suggested, are due to wave motion transmitted through the interior of the earth, and as in the presumably isotropic, or nearly so, material of the interior of the earth a separation of condensational and distortional waves could take place, which Knott and Rudzki have shown to be impossible in the rocks of which the surface of the earth is composed, it is suggested that these two phases are due to the arrival of the condensational and distortional waves respectively, travelling by brachisto-chronic paths through the interior of the earth.

This suggestion is followed up in the second paper. The published records of distant earthquakes were looked up, and those selected of which the time and place of origin were known within a limit of error of 1 minute of time and 1 minute of arc respectively. Further, on account of the known impossibility of separation of the two simple forms of elastic wave motion in the surface crust of the earth, only those records were considered which came from a distance of not less than 20° of arc from the epicentre.

Seven distinct earthquakes were found of which the published records satisfied all these conditions, and as in some of them there was more than one shock, they constituted eleven distinct shocks. From the published records were extracted (1) the time of commencement of the record; (2) the time of any sudden increase of movement, when recorded; and (3) the time of maximum displacement. Tabulating these, it is found that each earthquake exhibits a three-phase character in the record; and, further, that if the times are plotted and a curve drawn through them, the time curves of the first two phases show precisely that curvature which Prof. Rudzki's investigations show to be characteristic of wave motion propagated along brachistochronic paths through the earth, where the rate of propagation increases with the depth. Continuing these curves by extrapolation to the origin, they give rates of propagation fairly concordant with the rates of propagation of condensational and distortional waves as experimentally determined for ordinary rock. As a subsidiary part of this investigation, it is shown that the "preliminary tremors" of earthquakes coming from Japan to Europe reach a depth of about ·45 of the radius from the surface, attain there a maximum velocity of 14·5 km. per sec. for the condensational, and 8·8 km. per sec. for the distortional wave, and traverse a medium which has, at that point, a bulk modulus of 17 times, and a rigidity of about 21·5 times that of granite.

The records of the third phase show some irregularity, but the time curve is a straight line, pointing to a uniform rate of transmission along the surface. There is, however, some indication that in the case of the greatest earthquakes it is higher than in the case of lesser ones; in other words, that the rate of transmission is in some way dependent on the magnitude of the earthquake, hence, probably, on the size of the wave. From this it is concluded that the propagation of these surface undulations is, in part at least, gravitational.

## EXPLORATIONS OF THE "ALBATROSS" IN THE PACIFIC.[1]

WE left San Francisco in August of last year, and in latitude 31° 10′ N., and longitude 125° W., we made our first sounding in 1955 fathoms, about 320 miles from Point Conception, the nearest land. We occupied 26 stations until we reached the northern edge of the plateau from which rise the Marquesas Islands, having run from station No. 1, a distance of 3800 miles, in a straight line.

At station No. 2 the depth had increased to 2368 fathoms, the nearest land, Guadeloupe Island, being about 450 miles, and Point Conception nearly 500 miles, distant. The depth gradually increased to 2628, 2740, 2810, 2881, 3003 and 3088 fathoms, the last in lat. 16° 38′ N., long. 130° 14′ W., the deepest sounding we obtained thus far in the unexplored part of the Pacific through which we were passing. From that point the depths varied from 2883 to 2690 and 2776, diminishing to 2583, and gradually passing to 2440, 2463 and 2475 fathoms until off the Marquesas, in lat. 7° 58′ S., long. 139° 08′ W., the depth became 2287 fathoms. It then passed to 1929, 1802 and 1040 fathoms in lat. 8° 41′ S., long. 139° 46′ W., Nukuhiva Island being about 20 miles distant. Between Nukuhiva and Houa-Houna (Ua-Huka) Islands we obtained 830 fathoms, and 5 miles south of Nukuhiva 687 fathoms. When leaving Nukuhiva for the Paumotus we sounded in 1284 fathoms about 9 miles south of that island. These soundings seem to show that this part of the Marquesas rises from a plateau having a depth of 2000 fathoms and about 50 miles in width, as at station No. 29 we sounded in 1932 fathoms.

Between the Marquesas and the north-western extremity of the Paumotus we occupied nine stations, the greatest depth on that line being at station No. 31, in lat. 12° 20′ S., and long. 144° 15′ W. The depths varied between 2451 and 2527 fathoms, and diminished to 1208 fathoms off the west end of Ahii, and then to 706 fathoms when about 16 miles N.E. of Avatoru Pass in Rairoa Island.

Between Makatea and Tahiti we made eight soundings, beginning with 1363 fathoms, 2 miles off the southern end of Makatea, passing to 2238, 2363 (the greatest depth on that line), to 2224, 1930, 1585, 775, and finally 867 fathoms off Point Venus.

The deep basin developed by our soundings between lat. 24° 30′ N., and lat. 6° 25′ S., varying in depth from nearly 3190 fathoms to a little less than 2500 fathoms, is probably the western extension of a deep basin indicated by two soundings on the charts, to the eastward of our line, in longitudes 125° and 120° W., and latitudes 9° and 11° N., one of over 3100 fathoms, the other of more than 2550 fathoms, showing this part of the Pacific to be of considerable depth and to form a uniformly deep basin of great extent, continuing westward probably, judging from the soundings, for a long distance.

I would propose, in accordance with the practice adopted for naming such well-defined basins of the ocean, that this large depression of the Central Pacific, extending for nearly thirty degrees of latitude, be named Moser Basin.

The character of the bottom of this basin is most interesting. The haul of the trawl made at station No. 2, lat. 28° 23′ N., long. 126° 57′ W., brought up the bag full of red clay and manganese nodules with sharks' teeth and cetacean ear-bones; and at nearly all our stations we had indications of manganese nodules. At station No. 13, in 2690 fathoms, lat. 9° 57′ N., long. 137° 47′ W., we again obtained a fine trawl haul of manganese nodules and red clay; there must have been at least enough to fill a 40-gallon barrel.

The nodules of our first haul were either slabs from 6 to 18 inches in length and 4 to 6 inches in thickness, or small nodules ranging in size from that of a walnut to a lentil or less; while those brought up at station No. 13 consisted mainly of nodules looking like mammillated cannon-balls varying from 4½ to 6 inches in diameter, the largest being 6½ inches. We again brought up manganese nodules at the equator in about longitude 138° W., and subsequently—until within sight of Tahiti—we occasionally got manganese nodules.

As had been noticed by Sir John Murray in the *Challenger*, these manganese nodules occur in a part of the Pacific most distant from continental areas. Our experience has been similar to that of the *Challenger*, only I am inclined to think that these nodules range over a far greater area of the Central Pacific than had been supposed, and that this peculiar manganese-nodule bottom characterises a great portion of the deep parts of the Central Pacific where it cannot be affected by the deposits of globigerina, pteropods, or telluric ooze; in the region characterised also by red-clay deposits. For in the track of the great equatorial currents there occur deposits of globigerina ooze in over 2400 fathoms for a distance of over 300 miles in latitude.

We made a few hauls of the trawl on our way, but owing to the great distance we had to steam between San Francisco and the Marquesas (3800 miles) we could not, of course, spend much time either in trawling or in making tows at intermediate depths. Still the hauls we made with the trawl were most interesting, and confirmed what other deep-sea expeditions have realised: that at great depths, at considerable distances from land, and away from any great oceanic current, there is comparatively little animal life to be found.

The bottom temperatures of the deep (Moser) basin varied between 34·6° at 2628 and 2740 fathoms, to 35·2° at 2440 fathoms, and 35° at 2475 fathoms; about 120 miles from the Marquesas.

---

[1] Abridged from letters written to the Hon. George M. Bowers, U.S. Commissioner of Fish and Fisheries, Washington, D.C., by Mr. Alexander Agassiz, leader of the expedition of the U.S. Fish Commission Steamer *Albatross* to the Pacific.

Our deep-sea nets not having reached San Francisco at the time we sailed, we limited our pelagic work to surface hauls, of which we generally made one in the morning and one in the evening, and whenever practicable some hauls with the open tow nets at depths varying between 100 and 350 fathoms. The results of these hauls were very satisfactory. The collection of surface animals is quite extensive, and many interesting forms were obtained. As regards the deeper hauls with the Tanner net, they only confirm what has been my experience on former expeditions, that beyond 300 to 350 fathoms very little animal life is found, and in the belt above 300 fathoms a great number of many so-called deep-sea crustaceans and deep-sea fishes were obtained. I may mention that we obtained Pelagothuria at about 100 fathoms from the surface.

On our way to Tahiti from the Marquesas we stopped a few days to examine the westernmost atolls of the Paumotus. Striking Ahii we made for Rairoa, the largest atoll of the Paumotu group. Skirting the northern shore from a point a little west of Tiputa Pass. we entered the lagoon through Avatoru Pass, anchoring off the village.

We made an examination of the northern side of the lagoon between Avatoru and Tiputa Passes. The lagoon beach of the northern shore is quite steep, and is composed of moderately coarse broken coral sand at the base, and of larger fragments of corals along the upper face, which is about 5 to 6 feet above high-water mark. These coral fragments are derived in part from the corals living on the lagoon face of the northern shore, and in part of fragments broken by the waves from somewhat below the low-water mark. The ledge which underlies the beach crops out at many places on the lagoon side of the northern shore; we traced it also along the shores of Avatoru Pass, and about half-way across the narrow land running between Avatoru and Tiputa Passes. It crops out also at various points between them in the narrow cuts which divide this part of the northern land of the lagoon into a number of smaller islands. These secondary passes leave exposed the underlying ledge, full of fossil corals.

It became very evident, after we had examined the south shore of the lagoon, that the ledge underlying the north shore is the remnant of the bed, an old Tertiary coralliferous limestone which at one time covered the greater part of the area of the lagoon, portions of which may have been elevated to a considerable height. This limestone was gradually denuded and eroded to the level of the sea. Passages were formed on its outside edge, allowing the sea access to the inner parts of the lagoon. This began to cut away the inner portions of the elevated limestone, forming large sounds, as in the case of Fiji atolls, and leaving finally on the south side only a flat strip of perhaps 2500 to 3000 feet in width which has gradually been further eroded on the lagoon side, and also on the sea face to leave only a narrow strip of land about 1000 feet in width and perhaps 10 to 14 feet in height, the material for this land having come from the disintegration of the ledge of Tertiary limestone, both on the sea face and the lagoon side.

The underlying ledge is not the remnant of a modern reef; its character is identical with that of the elevated limestones of Fiji, which are of Tertiary age, and the rock is in every respect the same as that I observed on many of the elevated islands of Fiji. The atoll of Rairoa is in a stage of denudation and erosion very similar to that of Ngele Levu, in Fiji, only in Ngele Levu the elevated limestone attains a height of about 60 feet. Our visit to the south shore of the lagoon, both on the lagoon side and on the sea face, left us no doubt regarding the character of the underlying ledge of the north shore. As soon as the south shore was sufficiently near, as seen from the lagoon side, for us to distinguish its character, we could see that the entire shore line was formed of a high ledge of limestone, honeycombed, pitted and eroded, both by atmospheric agencies and the action of the waves, in its lower parts both on the lagoon side and on the sea face. The great rollers of the weather side broke through between the columnar masses of the ledge into the lagoon, and as far as the eye could reach there extended a more or less continuous wall.

Crossing over to the weather side of the southern land of Rairoa in one of the passages between two of the islands, we came upon the limestone ledge, from 12 to 14 feet high and about 40 to 50 feet wide, which formed the sea face of the islands and islets, and extended far to the westward as a great stone wall more or less broken into distinct parts. We found this ledge to consist of elevated limestone as hard as calcite, full of corals, honeycombed and pitted, and worn into countless spires and spurs, and needles and blocks of all sizes and shapes, separated by deep crevasses or potholes, recalling a similar scene in Ngele Levu on the windward end of the lagoon. In the passages the parts of the ledge which had not been eroded extended as wide buttresses, gradually diminishing in height till they formed a part of the lagoon flat and extended out below the recent beach rock which covered it in short stretches.

The amount of water which is forced into such a lagoon as Rairoa is something colossal, and when we observe that there are but a small number of passages through which it can find its way out again on the leeward side, it is not surprising that we should meet with such powerful currents (7 to 8 knots in several cases) sweeping out of the passages on the lee sides.

The islands and islets of Rairoa are fairly well covered with low trees and shrubs and large groves of palm trees.

It was with great interest that we approached Makatea, as it is the only high elevated island of which Dana speaks as occurring in the western Paumotus. For though he mentions some others as possibly having been elevated 5 to 6 feet, yet he considered them all, as well as Makatea (Metia or Aurora, of Dana) as modern elevated reefs. Yet, from the very description given by him of the character of the cliffs and of the surface of Makatea, I felt satisfied that it was composed of the same elevated coralliferous limestone so characteristic of the elevated reefs of Fiji, and which, from the evidence of the fossils and the character of the rock, both Mr. Dall and myself have been led to regard as of Tertiary age.

The cliffs had the same appearance as those of Vatu Leile, Ongea, Mango, Kambara, and many other elevated islands of Fiji. There were fewer fossils, perhaps, but otherwise the petrographic character of the rock was identical with that of Fiji.

The south-western extremity of the island sloped gradually to the sea, and showed two well-defined terraces. The lines of these two terraces could, as a rule, be traced along the faces of the vertical cliffs by the presence of caverns along the lines of those levels, similar to the lines of caverns indicating the line of present action of the sea at the base of the cliffs.

During our stay in Papeete some time was spent in examining that part of the barrier reef of Tahiti which had been surveyed by the *Challenger*. We found the condition of the outer slope of the reef quite different from its description as given in the *Challenger* narrative. The growing corals were comparatively few in number, and the outer slope showed nothing but a mass of dead corals and dead coral boulders beyond 16 or 17 fathoms, few living corals being observed beyond 10 to 12 fathoms.

We also made an expedition to Point Venus, to determine, if possible, the rate of growth of the corals on Dolphin Bank from the marks which had been placed on Point Venus by Wilkes, in 1839, and by MM. Le Clerk and de Bénazé, of the French navy, in 1869. We found the stones and marks as described, but on examining Dolphin Bank in the steam launch I was greatly surprised to find that there were but few corals growing on it. I could see nothing but sparsely scattered heads, none larger than my fist! the top of the bank being entirely covered by Nullipores, although we sounded across the bank in all possible directions and examined it thoroughly. It is greatly to be regretted that Dolphin Bank was not examined, neither in 1839 nor in 1869, and notes made of what species of corals, if any, were growing on its surface; for an excellent opportunity has been lost to determine the growth of corals during a period of 60 years. The choice of this bank as a standard to determine the growth of corals was unfortunate, as it is in the midst of an area comparatively free from corals.

From Papeete we steamed back to Makatea, and examined the island more in detail. We crossed the island from west to east, the path leading down from the summit of the cliffs bordering the island into a sink at least 40 to 50 feet lower than the rim of either face of the island. The sink occupies a little more than one-third the length of the island. It is deeper at its southern extremity, where it is said to be 75 to 100 feet below the rim of the adjoining cliffs.

It is difficult to determine if this sink is the remnant of the former lagoon of the island, or of a sound formed during its elevation, or if it has been formed by the action of rain and atmospheric agencies. The amount of denudation and erosion to which this island has been subjected is very great, as is clearly indicated by the small cañons, pinnacles, and walls of limestone, as well as by the crevasses which occur in the surface of the basin in all directions. The extent to which this action has penetrated into the mass of the island is also plainly shown by the great number of caverns which crop out at all levels along the sea face of the cliffs, some of which are of great height, and extend as long galleries into the interior of the island.

From Makatea, we visited Niau, Apataki, Tikei, Fakarava, Anaa, Tahanea, Raroia, Takume, Makemo, Tekokota, Hikuero, Marokau, Hao, Aki-Aki, Nukutavake, going as far east as Pinaki, when we turned westward again and made for the Gloucester Islands. These, as well as Hereheretue, proved most interesting; they formed, as it were, an epitome of what we had seen on a gigantic scale in the larger atolls of the western and central Paumotus. We could see at a glance in such small atolls as Nukutipipi and Anu-Anurunga the connection between structural features which, in an atoll of 40 miles in length and from 10 to 15 miles in width, it was often difficult to determine.

The deepest sounding among the Paumotus was on the line to the northward of Hereheretue in the direction of Mehetia, where we found a depth of 2524 fathoms, and a continuation of the red clay characterising the soundings since we left Pinaki.

We have seen nothing in this more extended examination of the group tending to show that there has anywhere been subsidence. On the contrary, the condition of the islands of the Paumotus cannot, it seems to me, be explained on any other theory except that in their present condition they have been formed in an area of elevation—an area of elevation extending from Matahiva on the west to Pinaki in the east, and from the Gloucester Islands on the south to Tikei on the north.

All the Paumotu Islands we have examined are, without exception, formed of Tertiary coralliferous limestone which has been elevated to a greater or less extent above the level of the sea, and then planed down by atmospheric agencies and submarine erosion, the greatest elevation being at Makatea (about 230 feet), and at Niau, where the Tertiary coralliferous limestone does not rise to a greater height than 20 feet. At Rairoa it was 15 to 16 feet high. At other islands it could be traced only as forming the shore platform.

The appearance of the old ledge and of the modern reef rock is so strikingly different that it is very simple to distinguish the two, even where only comparatively small fragments are found.

In the Paumotus, the islands have been elevated to a very moderate height, and probably to nearly the same height, for the old ledge forming the base of the modern structure is found exposed nearly everywhere at about low-water, when it cannot be traced at a slightly greater elevation. This would readily account for the nearly uniform height of the islands throughout the group.

But there is another element which comes into play in this group, and has an important part in shaping the ultimate condition of these atolls. At the Fijis we have seen the submarine erosion continue until there is little left of many of the atolls beyond the merest small islet or rock to indicate its structure. In the Paumotus, in the great atolls which are evidently only the exposed summits of parts of ridges or spurs of an extensive Tertiary coralliferous limestone bed, the rim of the atoll is, after having been denuded to the level of the sea, again built up from the material of its two faces, which is thrown up on the wide reef flats both from the sea face and from the lagoon side.

Many of the lagoons are filled with shoals or ledges awash or a few feet above the sea-level. These shoals are parts of the old ledge which have not as yet been eroded, and the disintegration of which has gone far to supply the material for the land of the outer rims of the atolls.

The lagoons of these atolls have a general depth of 13 to 20 fathoms. In some cases they are somewhat deeper, as is stated, but there are no measurements, the greater depths, 30 fathoms or more, being due to orogenic conditions. Some of the atolls are quite shallow, as at Matahiva, as well as Pinaki, where the lagoon is not more than 2 to 3 fathoms, and Takume, where it is from 5 to 6 fathoms deep. Some of the smaller islets we visited, among which are Tikei, Aki-Aki, and Nukutavake, have no lagoons.

The only atoll we have seen the lagoon of which is entirely shut off from the sea is Niau. In this case the old ledge forming the rim of the land, which surrounds the nearly circular lagoon, is about a third of a mile in width and sufficiently high, 15 to 20 feet, to prevent any sea from having access to it except in case of a cyclone. It is very difficult in this case to decide whether this lagoon has been gradually filled up after elevation, or whether it is merely a sink on a more or less uneven limestone surface.

Dana and other writers on coral reefs mention a great number of lagoons as being absolutely shut off from the sea. I take it these statements are due to their descriptions being taken from charts, many of which, as in the cause of the Paumotus, are very defective. For nothing is easier than to pass at a short distance by the wide or narrow cuts which give in so many cases the freest access to the sea to the interior of the lagoons, and described as closed because they have no boat passages. I could mention, as instances of such lagoons, those of the atolls of Takume, Hikuero, Anaa, &c., which may be said to be closed, yet into which a huge volume of water is poured at every tide over low parts of the encircling reef flats.

The character of the coral reefs of the Paumotus is very different from that of other coral reef regions I have seen. Nowhere have I seen such a small number of genera, so many small species, and such stunted development of the corals. None of the great heads of the genera so characteristic of the West Indian regions, or of the Great Barrier Reef of Australia, are to be seen, with the exception of a couple of species of alcyonaria they are absent, so far as our experience shows, and there are but few sponges and gorgonians to be found among the corals.

The same paucity of animal life seemed to extend to the deep-water fauna. All the hauls we made off the islands, in from 600 to 1000 fathoms, usually the most productive area of a sea slope, brought nothing, or so little that we came to grudge the time spent in trawling on the bottom, as well as towing on the surface or near it, a great contrast to the conditions in the Atlantic in similar latitudes, and very different from our anticipations.

From Papeete we steamed to Aitutaki, Niue, and for the deep hole of the Tonga-Kermadec Deep, about 75 miles to the eastward of Tonga-Tabu, and in 4173 fathoms made a haul with the Blake beam-trawl, by far the deepest trawl haul yet made. We found in the bag a number of large fragments of a silicious sponge belonging probably to the genus Crateromorpha, which had been obtained by the *Challenger* in the Western Pacific, but in depths less than 500 fathoms. We also brought up quite a large sample of the bottom; it consisted of light brown volcanic mud mixed with radiolarians.

On our way back to Papeete from the Paumotus we examined the eastern coast of Tahiti, and from Papeete studied the western coast as far as Port Phaeton, at Tararoa Isthmus. We also examined, in a general way, the Leeward Society Islands; Murea, Huaheine, Raiatea, Tahaa, Bora-Bora, Motu Iti and Maupiti. There are excellent charts of the Society Islands, so that it was comparatively simple to examine the typical points of the group and to gain an idea of their structure so far as it relates to coral reefs. The Society Islands are all volcanic islands edged with shore platforms, some of great width, upon which the barrier or the fringing reefs of the islands have grown. The structure of the reefs of the Society Islands is very similar to that of the Fiji reefs round volcanic islands. A comparison, for instance, of the charts of Kandavu, Viti Levu, Mbengha, Nairai, and of other volcanic islands in the Fijis, with those of the Society Group, will at once show their identity. Huge platforms of submarine denudation and erosion characterise both, with fringing and barrier reefs determined by local conditions. Perhaps it is easier to follow the changes which have taken place in the Society Islands; and such islands as Tahaa and Bora-Bora, where we anchored, as well as Maupiti, are admirable examples and epitomes of the structure and mode of formation of the coral reefs of that group.

The only island of the Cook Group which we examined was Aitutaki, as Atiu is composed of elevated limestone, and Rarotonga is volcanic; I hoped we might find that atoll to be in part volcanic and in part composed of elevated coralliferous limestone; we found it to be volcanic, an island with the structure of Bora-Bora on a smaller scale.

We anchored at Niue, an island composed of elevated coralliferous limestone showing three well-marked terraces, the lowest of not more than 5 to 10 feet and in many places disappearing completely, the limestone cliffs rising vertically from the sea well into the second or even the third terraces.

The second terrace varies in height from 50 to 60 feet, the third from 90 to 100 feet. The second terrace is deeply undercut; and in the higher vertical cliffs extending into the third terrace from the sea, the former positions of the terraces are usually indicated by lines of caverns.

From Niue we went to the Tongas, which we found a most interesting group. The elevated Tertiary coralliferous limestones take here their greatest development, and are on a scale far beyond that of their development in the Lau Group of the Fijis, or the Paumotus. The first island of the Tongas we visited, Eua, is perhaps the most interesting of the islands composed of Tertiary elevated coralliferous limestone I have visited. From Dana's account of it, evidently given at second hand, I expected to find an island somewhat like Viti Levu on a very much smaller scale. But as we steamed up to it from the east there could be no mistaking the magnificent face of nearly vertical limestone cliffs forming the whole eastern face of the island, and at points rising to over a thousand feet in height. At all projecting points lines of terraces were plainly marked: at the northern point three could be followed, and at the southern extremity five, with traces of a sixth perhaps.

Upon rounding the southern extremity of the island we could see that the island was composed of two ridges, running north, separated by a deep valley, the western ridge being much lower than the eastern, not rising to a greater height than a little over 500 feet. The western ridge is also composed of limestone, and at the headlands we could trace three terraces.

We anchored at English Roads, opposite the outlet of the drainage of the interior basin, where a small river has cut its way through a depression in the shore terrace. On landing we followed the crest of the western ridge for a few miles and could see the whole valley forming the basin of the island lying between the two ridges, at our feet. Nothing could show more clearly that such an island was not an elevated atoll, but a plateau which had been eroded and denuded for a long period of time by atmospheric and other agencies.

To the westward of the Tonga Islands is a line of volcanic islands extending nearly 200 miles, at a distance of from 15 to 20 miles parallel with the trend of the four irregularly-shaped plateaux upon which rise the Tonga Islands.

The Tonga-Tabu plateau is separated from the Namuka Group plateau by a funnel-shaped channel with a depth passing rapidly into 300 fathoms from the 100-fathom line. The Namuka plateau is rectangular; its principal island is Namuka, where we anchored.

This part of the Tongas is, like the Lau Group in Fiji, made up of islands in part volcanic and in part composed of elevated coralliferous limestone.

The Haapai plateau is triangular, with isolated islands rising on the north-western side from the deep water separating it from the Vavau plateau. On the northernmost plateau of the broad ridge of the Tonga Islands is the Vavau Group, by far the most picturesque of the Tonga Islands. Several parts of the island of Vavau, as at the entrance to the harbour of Neiafu, and at Neiafu, are finely terraced; four terraces are indicated there, and other flat-topped smaller islands show traces of two or three terraces. The northern edge of Vavau Island rises to a height of more than 500 feet, and slopes in a general way southward and inland. The southern shore is deeply indented by bays and sounds, and flanked by innumerable islands and islets, some of considerable height (150 to 250 feet) which gradually become smaller and smaller as they rise towards the southward and eastward, these islands having been formed from the denudation and erosion of the greater Vavau. They form tongues of land and sea and sounds of all shapes and sizes, showing the traces of the former land-connections of the islands and islets, and their disintegration on the eastward and southward by the action of the sea.

It is evident that in the Tonga Group, which is a very extensive area of elevation, the recent corals have played no part in the formation of the masses of land and of the plateau of the Tonga Ridge, and that here again, as in the Society Islands and the Cook Islands, both also in areas of elevation, they are a mere thin living shell or crust growing at their characteristic depths upon platforms which in the one case are volcanic, in the other calcareous, the formation of which has been independent of their growth.

After leaving Suva we steamed to Funafuti, stopping on the way at Nurakita, the southernmost of the Ellice Islands. I was, of course, greatly interested in my visit of Funafuti, where a boring had been made under the direction of a committee of the Royal Society, in charge of Prof. David, of Sydney, after the first attempt under Prof. Sollas had failed. The second boring reached a depth of more than 1100 feet. This is not the place to discuss the bearing of the work done at Funafati, as beyond the fact of the depth reached we have as yet no final statement by the committee of the interpretation put upon the detailed examination of the core obtained, and now in the hands of Prof. Judd and his assistants. In addition to the above-named islands, we also examined Nukufetau, another of the Ellice Group.

After leaving Nukufetau we encountered nothing but bad weather, which put a stop to all our work until we arrived under the lee of Arorai, the southernmost of the Gilbert Islands. On our way from Tapateuea we steamed to Apamama and Maiana, which we examined, as well as Tarawa. We next examined Maraki. Both Maraki and Taritari, the last island of the Gilberts which we examined, are remarkable for the development of an inner row of islands and sand-bars in certain parts of the lagoon parallel to the outer land-rim, a feature which also exists in many of the Marshall Islands atolls.

We spent about three weeks in exploring the Marshall Islands, taking in turn the atolls of the Ralick Chain to the north of Jaluit: Ailinglab Lab, Namu, Kwajalong and Rongelab; and then the atolls of the Ratack Chain: Likieb, Wotje and Arhno. The atolls of the Marshall Group are noted for their great size and the comparatively small area of the outer land-rims, the land-rims of some of the atolls being reduced to a few insignificant islands and islets. In none of the atolls of the Ellice, Gilbert or Marshall Islands were we able to observe the character of the underlying base which forms the foundations of the land areas of these groups. In this respect these groups are in striking contrast to the Paumotus, the Society Islands, the Cook Group, Niue, the Tongas, and the Fiji Islands, where the character of the underlying foundations of the land-rims is readily ascertained. But, on the other had, these groups give us the means of studying the mode of formation of the land-rims in a most satisfactory manner, and nowhere have we been able to study as clearly the results of the various agencies at work in shaping the endless variations produced in the islands and islets of the different atolls by the incessant handling and rehandling of the material in place, or of the fresh material added from the disintegration of the sea or lagoon faces of the outer land, or of the corals on the outer and inner slopes. It has been very interesting to trace the ever-varying conditions which have resulted in producing so many variations in the appearance and structure of the islands and islets of the land-rims of the different groups.

The boring at Funafuti will show us the character and age of the rocks underlying the mass of recent material of which the land-rim, not only of that atoll, but probably also that of the other atolls of the group and of neighbouring groups, is composed, though, of course, we can only judge by analogy of the probability of the character of the underlying base from that of the nearest islands of which it has been ascertained. When we come to a group like the Marshalls, we have as our guide only the character of the base rock of the islands of the Carolines, which is volcanic; while Naru and Ocean Islands, to the west of the Gilberts and to the south-west of the Marshalls, indicate a base of ancient Tertiary limestone.

The Marshall Islands, as well as the Ellice and Gilbert, seem to be somewhat higher than the Paumotus; but this difference is only apparent, and is due to the difference in the height of the tides, which is very small in the Paumotus, while in these groups it may be five and even six feet.

From Jaluit we visited among the Carolines, the islands and atolls of Kusaie, Pingelap, Ponapi, Andema, Losap, Namu, the Royalist Group, Truk and Namonuito, obtaining thus an excellent idea of the character of the high volcanic islands of the group from our examinations of Kusaie and of Ponapi, while the others represent the conditions of the low atolls, having probably a volcanic basis, but this was not observed at any of those we examined.

The reefs of the volcanic islands of the Carolines are similar in character to those of the Society Islands, though there are some features, such as the great width of the platforms of submarine erosion of Ponapi and of Kusaie, and the development of a border of mangrove islands at the base of the volcanic islands, which are not found in the Society Islands.

The Truk Archipelago was perhaps the most interesting of the island groups of the Carolines, and it is the only group of volcanic islands surrounded by an encircling reef that I have thus far seen in the Pacific which at first glance lends any support to the theory of the formation of such island-groups as Truk by subsidence. This group was not visited by either Darwin or Dana; and I can well imagine that an investigator seeing this group among the first coral reefs would readily describe the islands as the summits, nearly denuded, of a great island which had gradually sunk. But a closer examination will readily show, I think, that this group is not an exception to the general rule thus far obtaining in all the island groups of the Pacific I have visited during this trip; that we must look to submarine erosion and to a multitude of local mechanical causes for our explanation of the formation of atolls and of barrier and encircling reefs, and that, on the contrary, subsidence has played no part in bringing about existing conditions of the atolls of the South and Central Pacific.

Nowhere have we seen better exemplified than at Truk how important a part is played by the existence of a submarine platform in the growth of coral reefs. The encircling reef protects the many islands of the group against a too rapid erosion, so that they are edged by narrow fringing reefs, and nowhere do we find the wide platforms so essential to the formation of barrier reefs. The effect of the north-east trades blowing so constantly in one direction for the greater part of the year is of course very great; the disintegration and erosion of islands within its influence is incessant, and their action undoubtedly one of the essential factors in shaping the atolls of the different groups, not only according to the local positions of the individual islands, but also according to the geographical position of the groups. Thus far I do not think any observer has given sufficient weight to the importance of the action of the trades in modifying the islands within the limits of the trades, nor has any one noticed that the coral reefs are all situated practically within the limits of the trades both north and south of the equator.

The soundings made going west from Jaluit to Namonuito indicate that the various groups are, as is the case with the neighbouring groups of the Marshalls and Gilberts, isolated peaks with steep slopes rising from a depth of over 2000 fathoms. The line we ran from the northern end of Namonuito to Guam developed the eastern extension of a deep trough running south of the Ladrones. The existence of this trough had been indicated by a sounding of 4475 fathoms to the south-west of Guam made by the *Challenger*. We obtained, about 100 miles south-east of Guam, a depth of 4813 fathoms, a depth surpassed only, if I am not in error, by three soundings made by the *Penguin* in the deep trough extending from Tonga to the Kermadecs, and by three soundings made by the U.S.S. *Nero* also to the eastward of Guam.

Guam is not wholly volcanic; the northern half consists of elevated coralliferous limestone. The vertical cliffs bordering the eastern face rise from a height of 100 to 250 or 300 feet at the northern extremity, and resemble in a way similar islands in the Paumotus (Makatea), Niue, Eua, Vavau and others in the Fijis which had made their cliffs a familiar feature in our explorations. In fact, outside of Viti Levu and Vanua Levu, this is the largest island known to me where we find a combination of volcanic rocks and of elevated coralliferous limestone. The *massif* forming the southern half of the island is volcanic, and the highest ridge, rising to about 1000 feet, runs parallel to the west coast, the longest slope being toward the east.

This volcanic mass has burst through the limestone near Agaña, and the outer western extension of the coralliferous limestone exists only in the shape of a few spurs running out from the volcanic mass, the largest of which are those forming the port of San Luis d'Apra. Near the northern extremity of the island a volcanic mass, Mount Santa Rosa, has burst through the limestone and rises about 150 feet above the general level of that part of the island.

We left Guam in time to reach Rota by day, and found that this island is a mass of elevated coralliferous limestone, the highest cliffs of which reach a height of 800 feet. Perhaps in none of the elevated islands have we been able to observe the terraces of submarine elevation as well as at Rota.

It is quite probable that others of the Ladrones, like Saipan, and the islands to the south, are composed in part at least of elevated limestone, judging from the hydrographic charts and the sketches which accompany them. On many of the northern Ladrones there are active volcanoes, so that it is very possible that the volcanic outbursts which have pushed through the limestones, or have elevated parts of the islands of the group, are of comparatively recent date.

During the last part of our cruise, from Suva to Guam, the unfavorable weather greatly interfered with our deep-sea and pelagic work; in fact with the exception of the soundings made to develop as far as practicable the depths in the regions of the various coral-reef groups we visited, we abandoned all idea of carrying out the deep-sea and pelagic work planned for the district between the Gilbert and Marshall and Caroline groups. To our great disappointment hardly any marine work could be accomplished, and our investigations were limited almost entirely to the study of the coral reefs of the regions passed through.

We were everywhere received with the greatest cordiality and courtesy: by the Governor of the Paumotus, the King of Tonga, Sir George O'Brien (the High Commissioner of the Western Pacific at Suva), Mr. E. Brandeis (the Landes-Hauptmann in charge of the Marshall Islands at Jaluit), and the Governor of the Carolines, and the Japanese authorities.

The work of the expedition was divided between Drs. W. M. Woodworth, A. G. Mayer, and my son Maximilian, who accompanied me as assistants; and Mr. C. H. Townsend, Dr. Moore, and Mr. Alexander of the Fish Commission, who had also been detailed as members of the expedition.

I must also thank Capt. Moser and the officers of the *Albatross* for the untiring interest shown by them during the whole time of our expedition in the work of the ship, which was so foreign to the usual duties of a naval officer.

---

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

Mr. R. S. Clay, late lecturer in physics at the Birkbeck Institution, has been appointed principal of the Wandsworth Technical Institute.

The Secondary Education Bill was read a second time in the House of Lords on Monday, after a discussion in which objection was raised to the limited character of the measure, and the large powers reserved for the Board of Education. It is not proposed to carry the Bill beyond the second reading this year.

The first response to Mr. Chamberlain's appeal for further funds for the scientific department of the Birmingham University has been received from Sir James Chance, who has given the sum of 50,000*l*., subject to conditions to be arranged with the University Council. The endowment fund of the University now amounts to about 400,000*l*.

The Pass List for the 1900 D.Sc. Examination of the University of London contains the following names:—Experimental Physics: Reginald Stanley Clay, Richard Smith Willows, Harold Albert Wilson. Chemistry: Thomas Slater Price. Botany: Miss Maria Dawson. Zoology: Edgar Johnson Allen, Charles William Andrews.

Some interesting particulars with regard to chemical and technical education in the United States were given by Prof. Chandler, of New York, in his presidential address to the Society of Chemical Industry last week. The most striking feature of the American system of higher and technical education is the fact that most of the institutions have been founded and maintained by liberal gifts of money from wealthy citizens, in many cases made during the donor's lifetime, and that only a small number have been endowed or supported by the public funds. Thus in 1899 over 33 million dollars were given in this way, the largest sum being the 15 million dollars given by Mrs. Leland Stanford, together with large tracts of land, to which as yet no precise value can be attached, to complete the endowment of the Leland Stanford Junior University. There are in all 174 donors, averaging 190,000 dollars each. Schools of chemistry are now so numerous in the United States that it is almost impossible to state their exact number, but Prof. Chandler said it is more than 100. In all there are 480 universities and colleges, and 43 technical schools. In 1899 there were 9784 students pursuing professional courses in the schools of engineering, while 1487 graduated that year, receiving the degree of civil, mechanical, electrical, or mining engineer. The value to the industrial development of the United States of such an army of thoroughly-trained engineers and chemists cannot be too highly estimated.

The operations of the Technical Instruction Committee of the Cheshire County Council are extensive and satisfactory. All the sums received under the Local Taxation (Customs and Excise) Act of 1890 have been devoted to the promotion of technical instruction in Cheshire from the commencement. The Technical Instruction Committee has framed a scheme of work which has gradually embraced the whole county, and has provided for the various and special requirements of the different districts, as well as of the county at large. The annual report just received records a year's work of steady progress and development, more especially in regard to relatively advanced instruction, and improved methods of carrying on the classes. During the year ending March 31, 1900, the grants made for purposes of technical instruction amounted to nearly 17,000*l.*, and this sum will be considerably increased during the ensuing year. A number of secondary schools receive grants from the Committee, and it is proposed to increase the payments to such schools. As has been before remarked in these notes, assistance thus given is having a very important effect upon the character of the education in secondary schools; for a condition of the grant is that scientific subjects should be taught, and proper laboratory accommodation provided. We read, for instance, in the present report: "All the schools to which grants for building and equipping laboratories and lecture rooms were made have completed these additions, hence they are in a much better position to give sound instruction in science subjects, and especially in the practical stage, than they were formerly." It is well to bear in mind the beneficial influence which Technical Instruction Committees have thus had upon the curricula of Grammar Schools and others of the old-fashioned type. Among other matters dealt with in the report are experiments on tuberculosis in cattle, for which the Committee made a grant of 250*l.*, and experimental work in agriculture.

## *SOCIETIES AND ACADEMIES.*

### PARIS.

**Academy of Sciences**, July 16.—M. Maurice Lévy in the chair.—On the uranium radiation, by M. Henri Becquerel. By mixing uranium chloride with barium chloride and precipitating with sulphuric acid, a precipitate of barium sulphate is obtained which is more or less radio-active according to the quantity of barium salt introduced. The radio-activity of the uranium salt remaining undergoes a corresponding diminution. It cannot be settled from these experiments whether uranium salts possess a radio-active power of their own, or whether this property is due to an admixture of an impurity.—Preparation and properties of two borides of silicon, by MM. Henri Moissan and Alfred Stock. By heating together, with special precautions, in a tube of infusible material a mixture of silicon and boron in the electric furnace, two new borides of silicon are produced, $SiB_3$ and $SiB_6$, which can be separated by taking advantage of the facts that $SiB_3$ is more readily attacked by fused potash, and $SiB_6$ is more readily destroyed by concentrated nitric acid. Both compounds resist the attack of most reagents and are very hard, scratching ruby with facility.—On the crystallisation of gold, by M. A. Ditte. Gold leaf, heated with a mixture of salt and sodium pyrosulphate or ferrous sulphate, is attacked, and shows traces of crystalline structure, although the temperature has been far below that of the fusion of gold. Platinum gives rise to similar phenomena under the same treatment.—On the solubility of calcium phosphate in the water of soils in presence of carbon dioxide, by M. Th. Schlœsing. Neutral $Ca_3(PO_4)_2$, obtained free from sodium salts, is practically insoluble in water free from dissolved carbon dioxide. The solubility increases with the amount of dissolved carbonic acid, but if this is accompanied in solution with the corresponding amount of calcium bicarbonate, the solvent action is practically destroyed.—New researches on double fertilisation in angiosperms, by M. L. Guignard. In addition to the cases previously given of double fertilisation in monocotyledons, this has now been observed in *Narcissus poeticus* and *Scilla bifolia*. In dicotyledons, *Anemone nemorosa* has been most completely studied.—The movements of the air on encountering surfaces of different forms, by M. Marey.—Observations of the planets (F.G.) and (F.H.) made with the large equatorial of the Observatory of Bordeaux, by MM. G. Rayet and F. Féraud.—On the formation of coal basins, by M. Grand'Eury. Remarks on the mode of formation of the Loire basin.—M. Lipschitz was nominated a correspondent in the section of Geometry.—On the instability of certain periodic solutions, by M. Levi-Civita.—On the ternary bilinear forms of Hermite, by M. Louis Kollros.—On the law of corresponding states, by M. Daniel Berthelot. After discussing various modifications that have been suggested for bringing Van der Waals' formula into closer agreement with experiment, the author concludes that the three constants $f_c$, $v_c$, $T_c$ are not sufficient to rigorously define the function $f(p, v, T)$ of a substance. It is necessary to add two new constants, $T_m$ and $v_m$, corresponding to the displacements of the zeros of volume and temperature.—On the temperature of maximum density of aqueous solutions of ammonium chloride and lithium bromide and iodide, by M. L. C. de Coppet. The molecular lowering of the temperature of maximum density varied from 7·16 for ammonium chloride to 8·31 for lithium iodide.—On the electrolytic estimation of bismuth, by M. Dmitry Balachowsky. It is possible to get a coherent metallic deposit of bismuth allowing of washing, provided the following conditions are observed: slight acidity of the solution, absence of large quantities of halogen ions, matt electrodes, and low current density.—On the amalgams of sodium and potassium, by MM. Guntz and Férée. Four amalgams of mercury and sodium were isolated and analysed, $Hg_8Na$, $Hg_6Na$, $Hg_5Na$, $Hg_4Na$. Similar amalgams, although less clearly defined, were obtained with potassium.—On the reduction of tungstic anhydride by zinc: preparation of pure tungsten, by M. Marcel Delépine. Tungsten of a purity varying from 98·5 to 100 per cent. is obtained by heating zinc with tungstic anhydride or with ammonium tungstate.—Action of reduced nickel upon acetylene, by MM. Paul Sabatier and J. B. Senderens. Acetylene does not react upon reduced nickel in the cold if precautions have been taken to remove all traces of hydrogen from the metal by heating it in a current of nitrogen.—Action of cyanacetic esters with substituted acid radicles upon diazobenzene chloride and tetrazodiphenyl chloride, by M. G. Favrel.—On the limits of grafting in plants, by M. Lucien Daniel.—Action of dry and moist air upon plants, by M. Eberhardt. Compared with dry air, moist air increases the development of the plant, both leaves and stem, the diameter of the latter being reduced. It tends to exaggerate the leaf surface and to diminish the quantity of chlorophyll contained in the leaves.—The volcanic rocks of the Somali Protectorate, by MM. A. de Gennes and A. Bonard.—On a marine formation at the bottom of the Cañon of Regalon, by M. David Martin.—On certain substances specific in pellagra, by MM. V. Babès and E. Manicatide.

THURSDAY, AUGUST 2, 1900.

## WEAPONS AND WOUNDS.

*Les armes blanches; leur action et leurs effets vulnérants.* By H. Nimier, Professeur au Val-de-Grâce, and Ed. Laval, médecin aide-major de première classe. Pp. 448. (Paris: Félix Alcan, 1900.)

*Les projectiles des armes de guerre; leur action vulnérante.* By the same authors. Pp. 212. (Paris: Félix Alcan, 1899.)

*Les explosifs, les poudres, les projectiles d'exercice; leur action et leurs effets vulnérants.* By the same authors. Pp. 192. (Paris: Félix Alcan, 1899.)

THESE volumes, although their titles are formidable enough, can scarcely be said to exhaust the subject of the means invented by man for the special purpose of destroying his own race. Prof. Nimier, one of the authors, is well known as a writer on military medical subjects, and no doubt he has thought it unnecessary to repeat much of what he has already written on these and cognate subjects. The volumes, however, fill considerable gaps in our own literature. We have few writers in this country whose works stand out prominently as works of importance on the same subjects during the present century. Guthrie and Ballingall are practically the only writers whose contributions to the subject cover the period between the Peninsular and the Crimean Wars. Since then, Longmore's classical work on gunshot injuries was the sole work of reference until a year or two ago, when Stevenson, his successor in the Army Medical School at Netley, brought our knowledge of the injuries likely to be produced by modern fire-arms up to date. On the Continent the system of compulsory military service is responsible for the fact that these subjects excite widespread interest amongst the general and scientific public to a much greater extent than in England; and many important additions have been made to the literature of wounds in war by continental writers within the last few years.

The bulkiest of these three volumes treats of a class of weapons which nowadays play a comparatively unimportant part in wars between civilised Powers—namely, the bayonet, sabre, sword, lance and arrow. This volume also contains a chapter on defensive armour. We were much disappointed in finding that its bulkiness, instead of being due to pages full of historical detail, as we had anticipated, depends largely upon needless repetitions of the diagnosis, prognosis and treatment of the wounds produced in the different regions and tissues of the human body by the various weapons included in the term *armes blanches*. These repetitions are wearisome and unnecessary. The wounds produced by side-arms differ in no way from the contused, incised, punctured or poisoned wounds described in text-books on general surgery. In other words, there is no *specialism* in the subject for the student of physical, military or medical science, except perhaps that portion of it which deals with arrows and arrow poisons.

The volume, however, is of much value as a work of reference for any one desirous of comparing the shape and construction of the side-arms used by the several European Powers. The chapters on the bayonet and mixed types of bayonet are specially interesting in this respect. The introduction of the magazine rifle has led to important changes in the length and weight of the bayonet and to its probable use in future wars. The short knife-bayonet is now almost universally adopted; the shortest being the 21 centimètre long Norwegian bayonet, used with the Krag-Jörgensön rifle; as compared with the British Lee-Metford bayonet of 30 centimètres. The Austrian, German, Italian and Spanish bayonets hold an intermediate position between these two. Russia and France, on the other hand, still retain the long, narrow-pointed bayonet. Thus the Russian bayonet, 1891 pattern, measures 43 centimètres, and the French Lebel bayonet 52 centimètres with a weight of 466 grammes. Some idea of the slender stiletto-like proportions of the latter may be formed from the fact that, although nearly twice as long, it weighs actually less than the Lee-Metford bayonet. The authors enter somewhat fully into reasons why the Russians and French prefer this long weapon of offence to the shorter bayonet, which they describe as being intended more for lopping branches of trees and digging trenches than for any other purpose in war. They agree in thinking that, in modern pitched battles, the last phase, namely, the charge, *restera à l'état purement platonique*, one side yielding to the other without waiting for cold steel. But surprises, night attacks and assaults on convoys are circumstances of war which will occur as frequently in the future as in the past; and it is these that render the retention of the bayonet as a weapon of offence of paramount importance. The Russians recognise this fact so well that their cavalry carry a bayonet for use with the carbine. The authors also refer to the national temperament of the French as one of the reasons why they have not followed the example of neighbouring European countries in adopting a bayonet more suitable for camp purposes than as a weapon of offence. The French, they say, are specially fond of side-arms as weapons, by which we assume that the national temperament urges them to get to close quarters as soon as possible. This, however, seems scarcely sufficient reason for the preference they have for a long narrow bayonet. Our own soldiers, at any rate, have amply proved in the present campaign in South Africa that the short, stout bayonet possesses destructive and moral effects possibly equalled, but certainly not excelled, by the longer weapon. The authors have little to say that is of interest with regard to the sabre, sword and lance. The type of these weapons is practically the same in all civilised countries, and the chapters on them are mainly descriptive.

Arrows and arrow poisons are fully discussed, the chapter on them being mainly a *résumé* of the investigations made by the French naval surgeons, Le Dantec, whose tables of the geographical distribution and classification of arrow poisons are given in detail. The subject is occupying much attention at present in this country in consequence of the rapid extension of European spheres of influence in the African Hinterland, where poisoned arrows are so widely used by aboriginal tribes. Those who are interested in the subject will find accurate and important details in this chapter, but it must be confessed that English readers have fuller historical and scientific information available on arrow poisons in the inaugural address delivered by Prof. Stockmann, of Aberdeen University, to the North British Branch of the Pharmaceutical Society in 1898 (*Pharmaceutical Journal*, November 26 and December 3, 1898). It is interesting to note how thoroughly Prof. Stockmann's ethnological distribution of arrow poisons—a distribution which is extremely well marked—agrees with that of the French writers. In their description of the methods adopted for the propulsion of arrows and similar projectiles, the authors make no mention of the use of the blowpipe, a somewhat formidable weapon in the hands of Bornean aborigines.

In the chapter on defensive armour there is a guarded reference to what may prove of considerable importance in the future. In the helmet and cuirass we still possess the relics of a period when nations fought with sword and lance; but the opinion is gradually gaining ground that the use of defensive armour in the form of shields for protection against the projectiles of modern fire-arms may become a feature in future wars. The Danish Army have already adopted a form of shield for this purpose, and the principle is also recognised in the use of shields with the quick-firing automatic guns of the Maxim type.

The authors' contribution to the subject of projectiles deals with modern fire-arms only; and, with the exception that the projectiles of the automatic guns are not considered at all, the information on the subject is concise and complete. Modern small-arm projectiles are exceptionally well described. The physical qualities of these projectiles are remarkably similar in the different European countries, the chief variation in form being in the calibre of the bullet, which is between 6·5 and 7 millimètres sectional diameter for Italy, Holland, Norway, Roumania and Spain, and between 7 and 8 millimètres for other countries, the smaller calibre of the former being compensated for by greater length. The dynamic properties, however, have considerable and important variations, which the authors describe with the lucidity and precision characteristic of French writings on subjects of this nature. The chief practical interest in the dynamics of projectiles lies in the relationship between these properties and the surgical results. The principle to which the modern small-arm projectile owes its origin is indicated in the formula $f = mv^2$. In other words, the production of a bullet with a high rate of velocity at the expense of mass has been the object attained in the adoption of magazine rifles. But it is gradually dawning upon the military mind that the equation of work, expressed by the formula $o = \frac{mv^2}{2}$, does not express accurately the relative values of velocity and mass in the surgical results. The first occasion on which our own troops used the high velocity small calibre bullet in actual war—namely, in Waziristan in 1895—proved the fallacy of the formula in this respect; and it is now fairly well recognised that the mass of the projectile is probably as important a factor in producing surgical disaster as its velocity. No doubt the actual power of penetration and the resistance required to bring the projectile to a state of rest is accurately expressed by the formula; but it is this very power of penetration, depending so much on increase of velocity combined with reduction of mass, that has earned for the modern bullet the epithet humane. To pursue the subject further would lead to a variety of speculations as to the nature of the weapon of the future. The authors clearly recognise this, and are inclined to regard the action of the United States of America in reducing the diameter of the projectile of the naval small arm to 6 mm. as indicating a tendency to convert modern firearms into *carabines de salon* or *fusils d'enfants*. They are apparently much in sympathy with the use of bullets that deform or expand on impact, or at any rate produce shock, and fear that the agitation against these bullets will only lead to the use of some more deadly projectile in the future. These expanding or deforming bullets and their effects are fully described. The best known example is the soft-nosed Lee-Metford bullet, but the authors refer also to the use of the Lebel bullet with the hard envelope stripped at the apex. They state, however, that the latter does not expand on impact, although it produces shock. Another interesting example of the expanding bullet is the Swiss bullet, which has the lead core naked at the base instead of at the apex. The deformity in this bullet after impact, by the incurving of the soft base, is said to be as great as, if not greater than, the deformity at the apex of the Dum-dum type of bullet. The explosive effects sometimes caused by high velocity bullets are also very clearly discussed, but no new light is thrown upon this very curious phenomenon. The authors adhere to the generally accepted theory that the effects are due to secondary energy transmitted to tissues of a certain nature or in a certain state of tension. The possible part played by ricochets, deformities, and varying angles of impact is not mentioned in this connection. There is also entire absence of any reference to the use of true explosive bullets, which, although abolished by international agreement in 1868, are alleged to have been employed by some Boer commandos in the war that is now being waged in South Africa. The chapter on artillery fire is interesting and valuable, and concludes with a suggestive article on the moral effects of this branch of the service. In other respects the dynamics and ballistics of artillery projectiles and the wounding effects of fragments of shells, projectiles, &c., are worked out on the same lines as in the chapters on small-arm projectiles.

In the volume on explosives there is a variety of details, not readily obtained elsewhere in the same compact form, and on this account it is perhaps the most valuable of the three volumes to the student of military surgery or medical jurisprudence, to whom it is chiefly of interest. The effects of the various explosives in use are amply illustrated by historical incidents, especially incidents connected with anarchist attempts and with explosions in stores, ships and arsenals. The explosives used in the cartridges of the small-arms of different countries are also well described and compared. The authors include in this volume a chapter on the accidents connected with sapping and mining, a subject which we do not remember to have seen noticed in other works of a similar nature. The physical phenomena of a peculiar form of *intoxication* or suffocation to which sappers are liable are fully described and not generally known in this country.

The complete absence of bibliographic references is a notable defect in the volumes, more especially as they are mainly compilations of the works of other writers and investigators, whose names appear frequently in the authors' pages. In fact the reader, who might wish to consult the original works, will have great difficulty in knowing where to look for them. We are always glad, however, to welcome any contribution to a literature which is so meagrely represented in our own country.

W. G. M.

## *PLANTS OF THE PAST.*

*Éléments de Paléobotanique.* By R. Zeiller. Pp. 421. (Paris; Carré and Naud, 1900.)

SOME of the most striking advances in botanical science during the last two or three decades have been in the domain of Palæobotany. The study of fossil plants is now generally recognised as a science of primary importance, which affords, not merely useful data for the stratigraphical geologist, but furnishes valuable information as to the course of plant evolution, and enables us to connect some of the phyla of the plant-kingdom at points where their common origin is clearly indicated. Prof. Zeiller, of the École des Mines, Paris, has played a prominent part in placing fossil botany on a thoroughly scientific basis; his work, which embraces a wide field, is characterised by a philosophical handling of facts, a thoroughness of treatment and a breadth of view that are too frequently lacking in scientific writings of the present day. In the book before us Prof. Zeiller has performed a difficult task with considerable success. Within a small compass he has included a systematic though necessarily brief account of the more important types of fossil plants, and concise and clearly-written chapters on various subjects of geological and botanical interest. The illustrations are well executed, and it is a pleasure to note that many of them are new. In the section treating of the preservation of plants as fossils, Zeiller draws attention to a method of examination of "impressions" which he has used with considerable success. It is often possible, after suitable chemical treatment, to examine microscopically the thin carbonaceous film, which may sometimes be detached from the surface of a plant fragment lying on a slab of shale, and in this way to obtain important information as to anatomical details.

Some interesting examples of the Siphoneæ are figured and briefly described; but one or two of the examples quoted, *e.g.* the supposed *Caulerpa* from the Kimmeridge Clay, are of very doubtful value. The fossil Myxomycetes of Palæozoic age, described by Renault and other authors, should be mentioned with a word of caution as to their acceptance as undoubted Mycetozoa. In describing the vascular cryptogams, Zeiller notes the danger of attaching too much importance to the presence or absence of secondary wood, or to the isosporous or heterosporous character of a genus; mistakes made in the past, which have persisted for many years, emphasise the need of this caution.

In discussing the systematic position of various extinct generic types of exceptional interest which point to a common origin of cycads and ferns, Zeiller speaks of the collateral form of the vascular bundles as one of those cycadean characters which is met with also in recent ferns. It is, however, important to bear in mind the fact that in the collateral bundles of *Ophioglossum* and other ferns the protoxylem occupies an endarch position, while the cycadean type of bundle is usually mesarch.

The chapter on fossil ferns is particularly well done, and contains much that is new. The genus *Microdictyon*, mentioned by Zeiller as a mesozoic fern closely allied to *Laccopteris*, is hardly sufficiently distinct to be retained as a separate type.

The enlarged photograph of a leaflet of the well-known "fern," *Alethopteris Serlii*, given to illustrate the occurrence of what may possibly be traces of sporangia, does not afford satisfactory evidence that this fern-like frond bore fern-like sporangia. We are still in want of convincing evidence as to the nature of the reproductive organs of both *Alethopteris* and *Neuropteris*, genera in which the characters of ferns and cycads were combined.

A drawing is given of an exceptionally fine example of a rhætic fern—*Clathropteris platyphylla*—from Tonkin; as Zeiller has shown, this plant may be compared with the recent genus *Dipteris*, which, like *Matonia pectinata*, represents a tropical survival of a widely-spread mesozoic family of ferns. The inclusion of the genus *Sagenopteris* with the Hydropterideæ, rather than with the Filices, is perhaps a little rash, as the evidence so far available as to the reproductive organs is by no means conclusive.

A good description is given of the genus *Sphenophyllum*, but it is to be regretted that exigencies of space prevent full justice being done in this and other cases to the account of anatomical features. Zeiller discusses the possibility of *Sphenophyllum* having lived as a water-plant in the Coal period forests, but it is perhaps more probable that its long and slender stems were supported, like lianas, by the boughs of stouter trees.

In dealing with the Calamarieæ, Zeiller does full justice to the work of English authors, and discusses controversial points with admirable judgment and an open mind. The genus *Sigillaria* is described as a true lycopodiaceous plant, agreeing in certain respects with *Isoëtes*.

In the account of fossil cycads, Zeiller, like other authors, quotes an example of a cretaceous *Cycas* carpophyll, figured by Heer, from Greenland; the figured specimen, which the writer has seen in the Copenhagen Museum, is not sufficiently well preserved to be determined with certainty, and bears but a distant resemblance to Heer's figure. The genus *Podozamites*, placed by Zeiller among the Cycads, may possibly be more correctly included in the Coniferæ, but it is a type of somewhat doubtful position. The flowers of *Zamites gigas*, usually known as *Williamsonia*, mentioned in the section dealing with the Bennettiteæ, are usually of Inferior Oolite rather than Lower Lias age.

Prof. Zeiller gives a useful summary illustrating our knowledge of fossil angiosperms; as he points out, the literature on Tertiary plants is in urgent need of revision at the hands of experienced systematists. The concluding chapter, dealing with the bearing of palæobotanical evidence on plant evolution, is full of interest, and particularly valuable as being written by one who possesses both a wide knowledge of the available data and the power of critically weighing the evidence. Referring to the comparative study of species of fossil plants, Zeiller writes:

> "Les Espèces, commes les genres, se succèdent par voie de substitution et non par voie de transformation graduelle, et il en parait être de même à tous les niveaux."

A very useful bibliography of writings referred to in the text is given at the end of the volume. A. C. S.

## PHOTOGRAPHY IN NATURAL COLOURS.

*Lehrbuch der Photochromie* (*Photographie der natürlichen Farben*). Von Wilhelm Zenker; neu herausgegeben von Prof. Dr. B. Schwalbe. Pp. xiii + 157. (Braunschweig: Vieweg und Sohn, 1900.)

IN 1868, after long study and repetitions of Edmond Becquerel's experiments on photochromy, Dr. Wilhelm Zenker himself printed and published a "Lehrbuch der Photochromie," which contained a physical explanation of the colour-correctness of these photochromatic images. Zenker's book did not have a wide circulation—it would be difficult, perhaps, to name any one in England who has read it—and it was not until 1890 that Lippmann, by founding a *new* method on the principle suggested by Zenker, drew a slightly increased attention to Zenker's labours. That the attention was only slightly increased was due to two causes: firstly, the rather astonishing *results* of Lippmann and others helped to overshadow the *principle* of Zenker in the eyes of most people; secondly, among all those whose pursuits have any claim to be considered as scientific, English photographers are especially noticeable for their deliberate ignorance of the creative work of the past in photography.

For the latter reason, chiefly, the present writer has given, during the past year, a rather full analysis of Zenker's work in "Camera Obscura," and we have now a reprint, in good *English* type, of the book. In the words of the preface, "The more modern researches on photography in natural colours have shown that the way and the explanations of modern attempts are connected in many respects with Zenker's ideas." The volume contains besides a portrait of Zenker, a sketch of his life and index of his works by Prof. Gustav Krech; and, finally, Herr E. Tonn gives (pp. 131–157) an account of the further development of photochromy on the foundations of Zenker's theory. We shall notice these briefly in their order; but, with regard to the "Lehrbuch" itself, shall abstain from entering at all fully into the subject of its contents, as in the above-cited reference there is already a full account of it in English.

Wilhelm Zenker (1829–1899) cultivated many different branches of knowledge. His first papers (1850–1866) were zoological; the "Lehrbuch" was his first contribution to photography; and his other papers were on colour-perception (1867), photography and physical optics, astrophysics, and, in later life, meteorology. The "Lehrbuch," however, is probably the most important of his works, and it is to be hoped that now, with this excellent reprint, his methods will have some influence on English photography.[1]

The book is divided into three parts: (1) Considerations on colours ("Das Wesen der Farben"); (2) Account of his predecessors' work in photochromy ("Die Wiedergabe der Farben"); and the third part ("Theorie der Photochromie"), after an account of the theories of Seebeck, Becquerel and others, contains Zenker's own ideas (pp. 116–129). There are one or two useful notes to this section.

Herr Tonn's section, with one exception, seems very complete, and full references are given. It is, however, a pity that the very pregnant hint of Lord Rayleigh should be unnoticed (*Phil. Mag.*, 1887). Lord Rayleigh, independently of Zenker, and starting from totally different considerations, indicated in a footnote the Zenker principle, and even went farther; for not only did he seek to *explain* the results of Becquerel by this principle, but seemed to see the possibility of a *new* method of photochromy based on it. It would be interesting to have some account of Lord Rayleigh's then promised experimental investigations. If Herr Tonn knew this paper, it is difficult to understand how he resisted the temptation of comparing Rayleigh and Zenker—Zenker who was so clearly a non-mathematician.

The chief value of the book, the writer persists in believing, is not historical—for it *has* not had very much influence in the moulding of thought—but is in its spirit; the influence of its point of view and methods is needed above all at the present time for English photographers; this does not mean, of course, the small number of English *photo-chemists*.

PHILIP E. B. JOURDAIN.

## OUR BOOK SHELF.

*Die Harze und die Harzbehälter.* By A. Tschirch. Pp. viii + 417. (Leipzig: Gebrüder Borntraeger, 1900.)

THE author has spent eight years in collecting and arranging the scattered facts relating to the obscure group of organic compounds which are classified as resins by virtue of a common physical characteristic.

What Kekulé termed "the chemical lumber room" contained at one time a collection of similar obscure groups, such as the alcaloids, colouring matters, tannins, aromatic compounds, &c.; but since the year when that chemist gave to the world his benzene formula, the lumber room has been industriously ransacked and its contents dragged forth into the light of day. Perhaps the resins have received the scantiest share of attention; partly, no doubt, owing to the practical difficulties which they offer to the chemist.

We know nothing of the molecular state which finds its physical expression in these amorphous, translucent compounds, nor how to bring them into a condition of ascertained purity. How often does a promising research miscarry by the unwelcome appearance of resinous products! Nevertheless the mass of research which has accumulated on the subject fills 400 closely printed pages.

A great amount of this research gives very little indication of the nature of the resins themselves. The older chemists distilled them and obtained products such as benzoic acid, toluene, turpentine, &c. At a later date this severe method of treatment was replaced by the milder action of fused potash, with the result that a number of new aromatic acids and phenols were discovered. At the present time the separation of the various constituents of a resin is effected by the use of solvents and the numerous reagents which the resources of modern organic chemistry can offer. The results do not carry us very far. As the author says, "our march of conquest has only begun, and the present volume may suggest a successful plan of campaign." J. B. C.

---

[1] His work for the Paris Academy prize in 1868 stands in close relation to his theory of photochromy (see Fizeau's report, *Compt. rend.*, lxvi., lxvii.). Zenker's memoir was never published, and Otto Wiener (*Wied. Ann.*, 1890, 1895) later and independently followed the same train of thought. (*Cf.* also Cornu, Poincaré, Potier and Berthelot, *Compt. rend.*, cxii.; and Drude, *Wied. Ann.*, xli., xliii.).

*The Lepidoptera of the British Islands: a Descriptive Account of the Families, Genera and Species Indigenous to Great Britain and Ireland, their Preparatory States, Habits and Localities.* By Charles G. Barrett, F.E.S. Vol. vi. Parts 59-70. Heterocera (Noctuina—Geometrina). Pp. 388. Plates 233-280. (London: Lovell, Reeve and Co., Ltd., 1900.)

THE present instalment of Mr. Barrett's great work includes 110 species, from *Hoporina croceago*, Schiff., to *Halix wauaria*, L., and is written in the same exhaustive manner as previous volumes, giving all the information that a collector of British Lepidoptera (as such) is most likely to require. To Continental entomologists who wish to acquire an accurate knowledge of our limited insular fauna it would also prove very useful; though it is to be regretted that the bulk of the book, which may be expected to extend to nearly twenty volumes, and the unavoidable costliness of the larger edition issued with plates (which are not included in the cheap edition), must necessarily tend to restrict the sale. Those requiring it may therefore be recommended to obtain it volume by volume, or in monthly parts, as it appears, rather than to wait till the whole work is completed. We need not repeat our comments on earlier volumes, which will equally apply to the one before us; but the accounts given of the habits of the various moths discussed are always interesting, and sometimes curious; thus we learn that the rare *Cerastis erythrocephala*, Schiff., after its discovery in 1847, was met with occasionally till 1859, when it seems to have almost disappeared till 1872 and 1873, since when only one specimen, taken in 1894, has been found in England. The periodicity of the appearance of many species in these islands is curious, and has never been fully explained, for the causes which appear applicable to some cases will not explain others; and, moreover, uncertainty in the appearance of species seems to increase rather than to diminish. English names are not a conspicuous feature in this book, but Mr. Barrett notes that a recent writer has called *Xylina conformis*, Schiff., "The Conformist," and the next species, *X. lambda*, Fab., "The Nonconformist"! The resemblance of species of *Calocampa* and *Cucullia* to bits of stick is commented on; in fact, certain moths and larvæ thus fill the gap in our protected fauna caused by the absence of the stick insects proper, or Phasmidæ, which are not found nearer to our shores than the South of France. Several species noted in this volume seem to be now extinct in our islands; thus, *Chariclea delphinii*, L., does not seem to have been taken in England since about 1815. Their place has been taken by others; for example, the northern migration of *Plusia moneta*, Fab., reached England in 1890, and is probably still extending. Other moths of interest are those with cannibal larvæ, such as *Scopelosoma satellitia*, L., *Heliothis armigera*, Hübn., &c. There are many other interesting observations, which we have no room to quote, in the present volume, comprising, as it does, the conclusion of the Noctuæ, the Deltoidæ, and the first few species of the Geometræ. We may, however, note that the enigmatical *Sarrothripa revayana*, Schiff., is regarded by Mr. Barrett as a true *Noctua*, and is placed at the end of the *Noctuae Trifidae*.

W. F. K.

## LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Plankton of the Bay of Biscay.

WITH the valuable assistance of Mr. L. A. Borradaile, of Selwyn College, Cambridge, I have just completed a series of observations on the plankton of the Bay of Biscay extending over about three weeks, by means of opening and closing nets, as well as ordinary tow-nets. Our observations point to the fact (unexpected at any rate by myself) that the smaller Mesoplankton practically ceases at a depth of about 1000 fathoms. This conclusion agrees with that reached by Prof. Chun on the basis of the *Valdivia* Expedition (Deutsche Tiefsee Expedition, 1898–99, p. 44), with which, however, we were unacquainted until we had arrived at it independently. Below this limit we almost always captured a few specimens, as to which it was doubtful whether they were alive when captured, or were merely corpses of a shallower fauna sinking to the bottom, but in a few cases we at present incline to assign them to a living Mesoplankton.

We have also taken about 90 hauls under varied conditions at varied depths between 100 fathoms and the surface, which will eventually, we hope, give a fairly accurate basis for the determination of the vertical movements of the Epiplankton.

Our thanks are due to the Lords Commissioners of the Admiralty for placing the ship at our disposal, and to Captain Field and the other officers of the *Research* for their ungrudging assistance. G. HERBERT FOWLER.

H.M.S. *Research*, Devonport, July 27.

## THE TEACHING OF MATHEMATICS.

I THINK it very important to try to get a view of our system of teaching mathematics which is not too much tinted with the pleasant memories of one's youth. Like all the men who arrogate to themselves the right to preach on this subject, I was in my youth a keen geometrician, loving Euclid and abstract reasoning. But I have taught mathematics to the average boy at a public school, and this has enabled me to get a new view. I have seen faces bright outside my room become covered as with a thin film of dulness as they entered; I have known men, the best of their year in England in classics, lose in half an hour (as men did in the first day of slavery in old times) half their feeling of manhood; and I have known that, as an orthodox teacher of mathematics, I was really doing my best to destroy young souls. Happily, our English boys instinctively take to athletics as a remedy, and I know of nothing which gives greater proof of the inherent strength, in good instincts and common sense, of our race than this refusal to allow one's soul to be utterly destroyed. I have also mixed much with engineers, who really need some mathematics in their daily work, men who say that they once were taught mathematics, and I know that these men never use anything more advanced than arithmetic, and actually loathe a mathematical expression when it intrudes itself into a paper read before an engineering society. Of all branches of engineering, electrical engineering relies most upon exact calculation. Well, the average electrical engineer in good practice would rather work a week at many separate arithmetical examples than try for an hour to get out the simple algebraic expression, which includes all his week's results and much more. Yet he has passed perhaps certain rather advanced examinations in mathematics. Furthermore, those engineers who can most readily apply mathematics to engineering problems, almost invariably descend to the position of teachers and professors in schools and colleges, and they seem to lose touch completely with the actual life of their profession.

I have studied these phenomena very carefully, and I affirm that they are directly traceable to the absurd thing called mathematical teaching in schools and colleges.

The framers of educational methods took in their youth to abstract reasoning as a duck takes to water, and of course they assume that a boy who cannot in one year understand a little Euclid must be stupid. In truth, it is a very exceptional mind, and not, perhaps, a very healthy mind, which can learn things or train itself through abstract reasoning; nor, indeed, is much ever learnt in this way. Do we philosophise about swimming before we know how to swim; or about walking or jumping, or cycling or riding a horse, or planing wood, or chipping or filing metals, or about playing billiards or cricket? Is it through philosophy that we learn a game of cards, or to read or to write? No; we first learn by actual trial; we practice as our mind lets us; we philosophise afterwards—perhaps long afterwards. Then if we are too clever or stupid, we insist on teaching a pupil from the point of view which we have at the end of our studies, and we refuse to look at things from the pupil's point of view.

What a natural but ghastly statement the boy made who said: "Yes, Euclid and Xenophon, the beasts, wrote books for the third and fourth forms"! It is even a ghastlier notion that the jokesomeness of a philosopher, the unessential fringe of a subject, often becomes the soul-destroying, weary, worrying study of a schoolboy.

In a short article I shall not attempt to put forward my views as to how mathematics ought to be taught; I have published some of them in a summary of lectures on "Practical Mathematics," published by the Science and Art Department, and in my "Calculus for Engineers."

We let a Board School boy jump over all the ancient philosophy of arithmetic with its twenty-seven independent Greek characters (for our ten figures), the study of which required a lifetime, so that only old men could do multiplication, and they not only needed many hours to do one easy bit of multiplication, but declared that if the art were not practised every day it could not be remembered. Why not also let a boy jump over all the Euclidian philosophy of geometry, and assume even the forty-seventh proposition of the first book of Euclid to be true? Why not let him replace the second and fifth books of Euclid by a page of simple algebra, and give him much of the sixth book as axiomatic? If you must insist on abstract reasoning, you had better remember that nothing is really axiomatic; but any well-established truths may be looked upon as fundamental or axiomatic, and a system of abstract reasoning may be founded upon them. At present, a man at Cambridge finishes just where the really interesting and useful part of mathematics begins. There would not indeed be much difficulty in framing a course in which he would begin by studies where the studies of good mathematicians now end. This has been tried and proved successful. The present rules of the game are really a little too absurd. A difficult vector subject like geometry must be studied before algebra. Simple exercises on squared paper, well within the capacity of even illiterate persons, must not be approached until one has wasted years on higher algebra and trigonometry and geometrical conics, because they belong to the subject of co-ordinate geometry. It is assumed that it is not until after co-ordinate geometry is thoroughly studied that a man can take in the idea which underlies the calculus, an idea which is possessed by every young boy with absolute accuracy, and by every healthy mind.

Some friends of mine assert that no boy or man ought to be allowed to use logarithms until he knows how to calculate logarithms. They say this, knowing that the calculation is a branch of what is called higher mathematics, and that the average schoolboy, after six years at mathematics, finds it hopeless to even begin the study of the exponential theorem. It is a hard saying! It is exactly like saying that a boy must not wear a watch or a pair of trousers until he is able to make a watch or a pair of trousers. I am an advocate for the use by all students of all appliances which may be useful to them, whether made by tailors, or watchmakers, or instrument makers, or builders, or pure mathematicians. We need not believe a craftsman when he tells us that we cannot utilise his results without practising his trade. Nevertheless, it is good to be able to do some things for one's self, such as sewing on buttons, or using the lathe or a blowpipe, or the development of a little mathematics. If readers will refer to the above-mentioned *summary* they will see that I consider a good system of mathematics teaching of fundamental importance in the education of all men.

I must not dwell any longer on the imperfections of the existing system, but I hope that even readers who do not quite agree with me that much of the sixth book of Euclid ought to be regarded as axiomatic, will agree that what we usually call arithmetic is useless. For races not troubled with our abominable system of weights and measures, the whole of arithmetic consists merely of multiplication and division. To them a decimal is no more difficult to understand than an ordinary number. It is supposed that an English boy understands at once the meaning of 4,590,000 or 4590 or 459, but that such a number as 45·9 or ·459 or ·00459 is beyond his comprehension. I say that this is a difficulty artificially maintained by our stupid methods of teaching. Like the rest of our stupid methods, it is due to our unscientific ways of thinking. Because the embryo passes through all the stages of development of its ancestors, a boy of the nineteenth century must be taught according to all the systems ever in use and in the same order of time. The decimal system of stating numbers is 700 years old in Europe, but it was not till 280 years ago that Napier invented the use of decimals and the decimal point. Think of compelling all emigrants to pass to America through Cuba, because Cuba was discovered first. Think of making boys learn Latin and Greek before they can write English, because Latin and Greek were the only languages in which there was a literature known to Englishmen 450 years ago.

Again, the ingenious teachers of last century incorporated every kind of arithmetical example in a book and called each kind by a slang name—practice, interest, discount, tare and tret, alligation, position, &c., and we must teach exactly as they did. I do not mind retaining the buttons at the back of my coat; many useless ancient ceremonies may still be practised, and I shall not object. I can even admire them, but the unscientific waste of the valuable youth of millions of our people, now that we are face to face with nations who are determined to destroy England through commerce and war, is so abhorent to me that I cannot think of it with patience. It is not merely in arithmetic and geometry, but in the higher parts of mathematics that this waste goes on. Newton employed geometrical conics in his astronomical studies, and mechanics was developed; and therefore it is that every young engineer must study mechanics through astronomy, and he dare not think of the differential calculus till he has finished geometrical conics. The young applier of physics, the engineer, needs a teaching of mathematics which will make his mathematical knowledge part of his mental machinery, which he shall use as readily and certainly as a bird uses its wings; and we teach him in such a way that he hates the sight of a mathematical symbol all his life after.

It is just as in classics. Ask the average man if he ever reads anything now in Latin or Greek; ask him about anything to which he devoted ten years of his study at school, and he will answer that the only men he knows of who read the classics are a few famous scholars and the cads who read with delight cribs of the *Odyssey* and the *Iliad* just as if they were novels, because they never had the advantage of a classical education. But, of course, his mind was trained, he can always say that.

The authorities of the Science and Art Department recognise that apprentices and others attending evening classes may possibly benefit by a course of study very different from what is necessary if students are being prepared for university and other examinations. Hence, in addition to their very complete orthodox courses of instruction, they recognise the new method of study, the most elementary part of which is beginning to get crystallised in the following syllabus. There is also an "Advanced" syllabus, which is too long to be published here. I would advise interested persons to write to the Department for copies, and also for the report on the result of last year's examination, as well as for copies of the examination papers and of the above-mentioned summary.

I venture to hope for criticism of this syllabus—first, from men like my Cambridge friends, who are quite sympathetic, but who think the method one fit for evening classes only; second, from men who think with me that the method is one which may be adopted in every school in the country, and adopted even with the one or two boys in a thousand who are likely to become able mathematicians; third, from other men. Whatever be the point of view of any critic, he must surely feel that exhaustive criticism is important, for there are many large technical schools in England in which the method has already been adopted, the orthodox system being quite given up. I have been informed that the method is spreading rapidly in Germany also. I can already see from the exceedingly interesting examination results that crystallisation is proceeding rapidly, and if criticism is to be of value, now is the time for it. I hope also that the seemingly bumptious manner in which I criticise orthodox methods of teaching will not induce contemptuous indifference in men of thought. I hold a brief in the interests of average boys and men; my strong language and possible excess of zeal are due to the fact that nearly all the clever men have briefs on the other side.

JOHN PERRY.

## PRACTICAL MATHEMATICS.

### ELEMENTARY STAGE.

*Arithmetic.*—The use of decimals; the fallacy of retaining more figures than are justifiable in calculations involving numbers which represent observed or measured quantities. Contracted and approximate methods of multiplying and dividing numbers whereby all unnecessary figures may be omitted. Using rough checks in arithmetical work, especially with regard to the position of the decimal point.

The use of $5{\cdot}204 \times 10^5$ for 520400 and of $5{\cdot}204 \times 10^{-3}$ for ·005204. The meaning of a common logarithm; the use of logarithms in making calculations involving multiplication, division, involution and evolution. Calculation of numerical values from all sorts of formulæ.

The principle underlying the construction and method of using a common slide rule; the use of a slide rule in making calculations. Conversion of common logarithms into Napierian logarithms. The calculation of square roots by the ordinary arithmetical method. Using algebraic formulæ in working questions on ratio and variation.

*Algebra.*—To understand any formula so as to be able to use it if numerical values are given for the various quantities. Rules of Indices.

Being told in words how to deal arithmetically with a quantity, to be able to state the matter algebraically. Problems leading to easy equations in one or two unknowns. Easy transformations and simplifications of formulæ. The determination of the numerical values of constants in equations of known form, when particular values of the variables are given. The meaning of the expression "A varies as B."

Factors of such expressions as $x^2 - a^2$, $x^2 + 11x + 30$, $x^2 - 5x - 66$.

*Mensuration.*—The rule for the length of the circumference of a circle. The rules for the areas of a triangle, rectangle, parallelogram, circle; areas of the surfaces of a right circular cylinder, right circular cone, sphere, circular anchor ring. The determination of the area of an irregular plane figure (1) by using a planimeter; (2) by using Simpson's or other well-known rules for the case where a number of equidistant ordinates or widths are given; (3) by the use of squared paper whether the given ordinates or widths are equidistant or not, the "mid-ordinate rule" being used. Determination of volumes of a prism or cylinder, cone, sphere, circular anchor ring.

The determination of the volume of an irregular solid by each of the *three* methods for an irregular area, the process being first to obtain an irregular plane figure in which the varying *ordinates* or widths represent the varying *cross sections* of the solid.

Some practical methods of finding areas and volumes. Determination of weights from volumes when densities are given.

Stating a mensuration rule as an algebraic formula. In such a formula any one of the quantities may be the unknown one, the others being known.

*Use of Squared Paper.*—The use of squared paper by merchants and others to show at a glance the rise and fall of prices, of temperature, of the tide, &c. The use of squared paper should be illustrated by the working of many kinds of exercises, but it should be pointed out that there is a general idea underlying them all. The following may be mentioned:—

Plotting of statistics of any kind whatsoever, of general or special interest. What such curves teach. Rates of increase.

Interpolation, or the finding of probable intermediate values. Probable errors of observation. Forming complete price lists by shopkeepers. The calculation of a table of logarithms. Finding an average value. Areas and volumes, as explained above. The method of fixing the position of a point in a plane; the $x$ and $y$ and also the $r$ and $\theta$, co-ordinates of a point. Plotting of functions, such as $y = ax^n$, $y = ae^{bx}$, where $a$, $b$, $n$, may have all sorts of values. The straight line. Determination of maximum aud minimum values. The solution of equations. Very clear notions of what we mean by the roots of equations may be obtained by the use of squared paper. Rates of increase. Speed of a body. Determination of laws which exist between observed quantities, especially of linear laws. Corrections for errors of observation when the plotted quantities are the results of experiment.

In all the work on squared paper a student should be made to understand that an exercise is not completed until the scales and the names of the plotted quantities are clearly indicated on the paper. Also that those scales should be avoided which are obviously inconvenient. Finally, the scales should be chosen so that the plotted figure shall occupy the greater part of the sheet of paper; at any rate, the figure should not be crowded in one corner of the paper.

*Geometry.*—Dividing lines into parts in given proportions, and other illustrations of the 6th Book of Euclid. Measurement of angles in degrees and radians. The definitions of the sine, cosine and tangent of an angle; determination of their values by drawing and measurement; setting out of angles by means of a protractor when they are given in degrees or radians, also when the value of the sine, cosine or tangent is given. Use of tables of sines, cosines and tangents. The solution of a right angled triangle by calculation and by drawing to scale. The construction of a triangle from given data; determination of the area of a triangle. The more important propositions of Euclid may be illustrated by actual drawing; if the proposition is about angles, these may be measured by means of a protractor; or if it refers to the equality of lines, areas or ratios, lengths may be measured by a scale and the necessary calculations made arithmetically. This combination of drawing and arithmetical calculation may be freely used to *illustrate* the truth of a proposition.

The method of representing the position of a point in space by its distances from three co-ordinate planes. How the angles are measured between (1) a line and plane; (2) two planes. The angle between two lines has a meaning whether they do or do not meet. What is meant by the projection of a line or a plane figure on a plane. Plan and elevation of a line which is inclined at given angles to the co-ordinate planes. The meaning of the terms "trace of a line," "trace of a plane."

The difference between a *scalar* quantity and a *vector* quantity. Addition and subtraction of vectors.

Slope of a line; slope of a curve at any point in it. Rate of increase of one quantity $y$ relatively to the increase of another quantity $x$; the symbol for this rate of increase, namely, $\frac{dy}{dx}$; how to determine $\frac{dv}{dx}$ when the law connecting $x$ and $y$ is of the form $y=ax^n$. Easy exercises on this rule.

In setting out the above syllabus the items have been arranged under the various branches of the subject.

It will be obvious that it is not intended that these should be studied in the order in which they appear; the teacher will arrange a mixed course such as seems to him best for the class of students with whom he has to deal.

## ANALYTICAL PORTRAITURE.

IT seems well to put on record the principal results of experiments that I have recently made to *isolate the particulars* in which one portrait differs from another. They had a measure of success, but not enough to deserve illustration or lengthy description. The objects I had hoped to attain are important; namely, to define photographically the direction and degrees in which any individual differs from the race to which he belongs, the race being represented by a composite picture of many individuals belonging to it. Or, again, to define the particulars in which any variety of a plant or animal differs from its parent species. Or to define family features; or to isolate expressions, recollecting that these consist both of subtractions from, and additions to, the features as seen in repose.

My starting point was that the exact superimposition of a rather faint positive upon its rather faint negative produces an approximately uniform grey, when they are viewed as a single transparency. Thus, I photographed a rotating disc that had been faced with white paper and divided into concentric rings. The innermost disc was left white, the outermost ring was painted black, and the intermediate rings contained successively increasing proportions of black to white. The photographic negative showed rings of graded tints, and from this I took a positive by contact. Subsequently applying the positive to the negative, film to film, and viewing them as a transparency, a nearly uniform grey surface was produced. It was necessary to superimpose them with exactness; otherwise the edges of the rings were conspicuously dark in one part, and light in the opposite part. Another test experiment was to paste together thicknesses of tracing paper—two-fold, three-fold, &c., up to twelve-fold—to cut distinctively shaped snippets of these and to variously distribute them over the surface of a glass plate, which was then photographed, and a positive taken as well. On treating the positive and negative as above, all the tints between those of the three-fold and the nine-fold inclusive produced a uniform grey.

Let A and B be any two pictures whose respective negatives and positives will be called *neg. a*, *pos. a*, *neg. b*, *pos. b*. My object was to produce photographically a third pictue X which should express the difference between A and B; that is, should be equal to A—B, or else a fourth picture Y which should represent B—A.

It will, however, be simpler to treat the problem at first as an optical one, based on the following equations:—

$$\text{(I.) } pos.\ a + neg.\ a = grey\text{; (II.) } pos.\ a + x = pos.\ b$$

(if treated as a photographic problem, (II.) would be replaced by $pos.\ a + x = neg.\ b$). From these we obtain

$$\text{(III.) } pos.\ a + \{pos.\ b + neg.\ a\} = pos.\ b + grey$$

and

$$\text{(IV.) } pos.\ b + \{pos.\ a + neg.\ b\} = pos.\ a + grey.$$

Calling the terms within brackets by the name of "transformers," the transformer of $b$ into $a$ is the negative of the transformer of $a$ into $b$. The two terms within brackets may be "composited" together on equal terms, then the result may be composited with the first term, allowing two-thirds of the total time of exposure to the transformer, and one-third to the first term. Or, what comes to the same thing in the end, all three terms may be composited in equal shares, allowing one-third of the total time of exposure to each. The transformers in (III.) and (IV.) being respectively $x + grey$ and $y + grey$, are nearly equivalent for the purposes of the inquiry to $x$ and $y$, because the addition of a uniform shade of grey has little or no effect on pictorial resemblance. A portrait does not cease to resemble the original when it has become somewhat browned by exposure to a London atmosphere, or when it is viewed in shade, or under a tinted glass. Its distinctiveness depends on the *differences* (not the ratios) being preserved between the tints of all adjacent elements of its surface. Of course the grey must not be too dark; otherwise the deeper tints of the portrait would appear indistinguishably black.

This method of transformation succeeds fairly well. I changed an F on a white ground into a good G on a grey ground, and I changed with passable success one portrait A on white ground into another portrait B on grey ground, but the transformer itself gave little of that information to the eye which I had expected. It *must* have nearly isolated, but it failed to exhibit in an intelligible form the differences between A and B. Then I photographed two faces, each in two expressions, the one glum and the other smiling broadly. I could turn the glum face into the smiling one, or *vice versa*, by means of the suitable transformer; but the transformers themselves were ghastly to look at, and did not at all give the impression of a detached smile or of a detached glumness.

Part of the ghastliness was due to the different densities of the superimposed positives and negatives, which did not neatly obliterate one another in the unchanged portions of the face, and part was due to their not being superimposed in the best possible way. There can be no doubt of the best fit when engaged in making the transformer of an I into an L; but the eye must determine the best fit and proportions of the two components of the transformer of one portrait into another. I cannot yet make up my mind whether or no the process admits of substantial improvement, but feel sure that the only satisfactory experiments now would be those made by two converging lanterns on a screen, one at least of which admits of easy and delicate adjustment in direction and in the intensity of its illumination. The most suitable portraits for the attempt are apparently such as are popularly, and sometimes reproachfully, termed "artistic," that is to say, with blurred outlines and medium tints; certainly not those which in photographic language are called "plucky." I have no means in my house for experiments of this kind, but perhaps a trial might be made in some laboratory where they exist. The point is to ascertain whether the images of *neg. a* and *pos. b* can be so combined on the screen as to give an intelligible and useful idea of the differences between A and B.

FRANCIS GALTON.

## A RECOLLECTION OF KING UMBERTO.

HOW enthusiastically the late King of Italy could devote himself to the welfare of science and art, those of us who were at Como last September had an opportunity of seeing. One very hot day he arrived with the Queen and the Duke of Naples by train from their palace at Monza, near Milan. First they made an official inspection of the galleries and machinery in the Silk and Electricity Exhibition, then they visited the Exhibition of Sacred Art, and, after lunch, they opened the Electrical Congress, held to celebrate the Volta centenary.

This was a no mere regal opening occupying a fraction of an hour, for a solid afternoon's work was done in receiving various addresses and listening to a long lecture on Volta and his pile, in which Volta's work was described at length, and even discussed from the modern standpoint of the ionic theory of voltaic action. Finally, the king had several foreigners presented to him, and he chatted with us about the things in which *we* were interested.

But even this was not enough for one day's work, since, before leaving, the Royal party went to the cathedral to listen to the new oratorio, *The Nativity*, which was exciting so much interest in Como at that time.

Such a keen personal interest in science and art made the king much loved by a people who venerate even the tomb of a worker like Volta. And those of us who saw King Umberto only at Como last year feel that it is not merely a king, but a friend who has now been killed.

W. E. Ayrton.

## NOTES.

On Monday next, August 6, the International Congress of Physics will be opened at Paris with an address by the president, Prof. Cornu. The Congress will then be divided into the seven following sections, which will meet in the rooms of the Société française de Physique: (1) general questions, instruction, measurements; (2) mechanical and molecular physics; (3) optics; (4) electricity and magnetism; (5) magneto-optics, radio-activity, discharges in gases; (6) cosmical physics; (7) biological physics. As many of our readers are aware, much attention has been given to the organisation of the Congress. The secretaries of the committee, Prof. Poincaré and Dr. Guillaume, have been entrusted with the production of three volumes, already in the press, containing more than seventy reports on physical questions of current interest and importance, contributed by physicists of various nationalities. Among the subjects dealt with by British physicists are: the movements produced in an indefinite solid by the displacement of a material body, by Lord Kelvin; the constant of gravitation, by Mr. C. V. Boys; the propagation of electricity, by Prof. Poynting; electric discharges in gases, by Prof. J. J. Thomson; properties of alloys, by Sir W. C. Roberts-Austen; and the unit of heat, by Mr. E. H. Griffiths. In addition there are contributions by Profs. Lorentz, van 't Hoff, Warburg, Voigt, van der Waals, H. Poincaré, Cornu, Lippmann, Potier, Becquerel, Arrhénius, Exner, Spring and others. The sectional meetings will partly be held simultaneously and partly at different hours, in order to give members an opportunity of hearing papers of interest to all physicists. In addition to the serious work of the Congress, provision has been made for lighter entertainment. The Municipal Council of Paris will hold a reception on Tuesday, August 7, and the French President will give a reception to the members on August 9. Prince Roland Bonaparte will give a soirée on August 11, and in his splendid library an exhibition of new apparatus and experiments will be held. There is thus every promise that the meeting will be both interesting and pleasant to all who are able to take part in it.

It is announced that permission has been granted for the Institution of Electrical Engineers to hold a reception in the British Royal Pavilion in the Paris Exhibition from 5 to 7 p.m., on Wednesday, August 22, and that arrangements for the reception are being made accordingly.

We learn from *Science* that the New York Board of Estimate and Apportionment has authorised the expenditure of 200,000 dollars for the Botanical Garden, and 150,000 dollars for an addition to the American Museum of Natural History.

Mr. Leonard S. Loat, who is investigating the fishes of Egypt for the British Museum and the Egyptian Government, was last heard of at Korti, where he reports (on May 18) a hot wind and a temperature of 115° in the shade. He had sent home upwards of 2200 specimens of Nile-fishes to the Natural History Museum, and as soon as the river had risen sufficiently would proceed to Senaar and Khartoum.

Mr. J. S. Budgett, who is engaged in collecting fishes on the River Gambia, dates his last letters (June 22) from McCarthy's Island in the interior. There had been a disturbance in the colony, and one of the Commissioners and a party of police were believed to have lost their lives; but this had not affected Mr. Budgett's operations, and he had a large number of Polypteri and Protopteri in floating cages in the river. He was in good health, and expected to be home again in September.

The Rocky Mountain Goat (*Haploceros montanus*) in the Zoological Society's Gardens has now put on its full white summer dress, and is well worthy of inspection. This animal, until lately, was supposed to be the only representative of the Mountain or Goat-like Antelopes in the New World, but a second species of the same genus has recently been discovered in Alaska, and named by Mr. D. G. Elliott, of Chicago, *Oreamnus kennedyi*. The form is no doubt closely allied to *Nemorhaedus* of the mountain ranges of Asia, and probably found its way to the New World in company with the Rocky Mountain Sheep and Wapiti Deer.

The *Electrician* states that the German Electro-Chemical Society is arranging to hold its seventh annual meeting at Zürich on August 5-7. In addition to the reading of a number of papers, visits are to be paid to the Polytechnic and to the works of the Oerlikon Co.

The Moxon gold medal of the Royal College of Physicians, founded in 1886 in memory of the late Dr. Walter Moxon, and awarded every third year for distinction in clinical medicine, has been awarded to Sir William T. Gairdner, K.C.B., F.R.S., Emeritus professor of medicine in the University of Glasgow. Prof. Clifford Allbutt will deliver the Harveian Oration on October 18 (St. Luke's Day); and Dr. A. E. Garrod, the Bradshaw Lecture in November. Dr. Henry Head has been appointed the Goulstonian, Dr. J. Frank Payne the Lumleian, and Dr. Halliburton the Croonian Lecturer for 1901, and Dr. J. W. Washbourn the Croonian Lecturer for 1902.

We are indebted to Mr. C. Repington, of Bridge End, Ockham, Surrey, for some eggs of the Wood Leopard Moth (*Zeuzera Æsculi*). They resemble strings of small oval beads, of a yellowish testaceous colour. The moth, although reputed scarce, is commoner round London than is generally supposed, and would be very destructive, if its numbers were not kept down by birds, notably by sparrows and woodpeckers. The eggs might be reared by placing them in chinks of the bark of almost any deciduous tree (apple, elm, &c.). The larvæ feed, like those of the Goat Moth (*Cossus ligniperda*), in the wood of growing trees, but are much less common.

Questions referring to the Marine Biological Association were asked in the House of Commons on Thursday last, and were replied to by Mr. Ritchie as follows:—"In 1885, the Treasury, when agreeing to a grant to the Plymouth laboratory of the Marine Biological Association, made it a condition 'That the council undertakes to place space in the Plymouth laboratory at the disposal of any competent investigator deputed by a recognised authority to carry out any investigation into fish questions for which the laboratory can give facilities.' The Board of Trade have never employed any naturalist to make investigations on fishes at the laboratory, and they have no staff or funds to devote to such a purpose. I have no information as to what has been done by other Government authorities. The Board of Trade have occasionally consulted the council of the Marine Biological Association on fishery subjects. The latest occasion had reference to the question of a fisheries exhibit at the Paris Exhibition. The inspectors of the Board of Trade have on many occasions consulted the officials of the association in an informal manner. The association were not directly consulted by of the Board Trade as to the Bill dealing with undersized fish, which, however, was founded on the recommendations of the Select Committee of 1893, who took evidence from the association."

THE sixty-eighth annual meeting of the British Medical Association was opened at Ipswich on Tuesday under the Presidency of Dr. W. A. Elliston. An address in medicine was delivered on Wednesday by Dr. Philip Henry Pye-Smith, F.R.S.; an address in surgery will be delivered to-day by Dr. Frederick Treves; and an address in obstetrics will be delivered by Dr. William J. Smyly on Friday. The scientific business of the meeting is being conducted in thirteen sections, as follows, namely: Medicine; surgery; obstetrics and gynæcology; State medicine; psychology; physiology; pathology; ophthalmology; diseases of children; pharmacology and therapeutics; laryngology and otology; tropical diseases; navy, army and ambulance. The exhibits in the annual museum held in connection with the meeting are arranged in the following sections:—Section A: Food and drugs, including prepared foods, chemical and pharmaceutical preparations, &c.; Section B: Instruments, comprising medical and surgical instruments and appliances, electrical instruments, microscopes, &c.; Section C: Books, including diagrams, charts, &c.; Section D: Sanitary appliances and ambulances.

THE address of Mr. E. M. Holmes, the president of the British Pharmaceutical Conference held in London last week, and most of the papers read and discussed at the meetings, are published in full in the current number of the *Pharmaceutical Journal*. Mr. Holmes reviewed the progress of science, so far as it affected pharmacy, during the present century, and indicated some of the changes which have occurred. Referring to the subject of an international Pharmacopœia, he remarked:—"A General Pharmacopœia, that would enable a pharmacist to dispense a prescription with uniformity in any pharmacy on the Continent, may be regarded as a Utopian rather than a practical idea, and could only be attained by alphabetically arranging in dictionary form all the formulæ in all the known pharmacopœias. But there can be no reason why an approach towards it should not be made by a congress of medical men and pharmacists, limiting their attention, in the first place, to poisonous preparations only, and, in order to avoid international jealousies, adopting as a standard the formulæ that approach nearest to decimal proportions. The comparison of different formulæ is rendered a simple matter by the publication of the different strengths of preparations of the various pharmacopœias in Squire's 'Companion to the British Pharmacopœia.' The next step might be to make uniform the strength of the most generally used preparations that are not poisonous. A really useful International Pharmacopœia cannot be otherwise than a gradual growth."

AMONG the papers printed in the *Pharmaceutical Journal* are several of interest outside pharmaceutical circles. Mr. E. J. Parry shows that the so-called santalol, which exists to the extent of about 90 per cent. in sandal-wood oil, is a mixture of two or more bodies of an alcoholic nature, one of which is that to which the name santalene has been applied. Mr. T. H Wardleworth deals with some pharmaceutical and economic plants of Jamaica. As the result of a visit to that island he is of opinion that pharmacists would do well to attempt to obtain from British colonies supplies of many drugs which at present come from other parts of the world. Messrs. T. Tyrer and A. Levy continue their investigation on melting points, the substances more recently examined being salicylic acid, salol, carbolic acid, menthol, and thymol. Messrs. C. T. Tyrer and A. Wertheimer have made a careful physical examination of American, Russian, and French turpentine oils and terebene made therefrom, and propose, at some future date, to investigate similar products from all possible sources. As a general rule they find that the higher the initial rotation of American turpentine the smaller is the product of inactive mixture capable of steam distillation and the higher the specific gravity. French turpentine has a greater tendency to oxidise than American, being intermediate between that and the Russian oil. Dr. F. B. Power summarises the methods which have been advocated for the preparation of mercurous iodide, and gives the results of determinations of the amount of iodine or pure mercurous iodide contained in specimens of the compound made in different ways. These results indicate that precipitated mercurous iodide is quite uniform in composition and also sufficiently stable when properly protected. Mr. E. Dowzard thinks that useful information may be obtained by determining the viscosity of essential oils. A specimen of pure lemon oil had a viscosity of 139·6, whilst that of citrene was found to be 195·8, and that of a mixture of citrene with 7·5 per cent. of citral was 114·9.

H.M.S. *Viper*, which it will be remembered is driven by the "Parsons' steam turbine system" (built by the patentees at their works at Newcastle for the British Government, and described and illustrated in NATURE of March 1), has this month not only broken her own record of 35½ knots, but proved to possess qualifications equally important in marine engineering. On six consecutive runs (says *Engineering*, July 20) the following speeds were attained:—

| Time on measured mile | Equivalent speed in knots |
|---|---|
| m. s. | |
| 1 38$\frac{2}{5}$ | 36·585 |
| 1 41$\frac{2}{5}$ | 35·503 |
| 1 37 | 37·113 |
| 1 38$\frac{2}{5}$ | 36·585 |
| 1 37 | 37·113 |
| 1 39$\frac{4}{5}$ | 36·072 |

The mean of two runs with and against the tide was 36·845 knots. The Admiralty mean of the six runs over the mile, with and against the tide, was 36·581 knots, which speed was also the mean for the hour's run. The mean revolutions for the hour's run was 1180 per minute. The steam pressure in the turbines ran up to 200 lbs. per square inch, and the mean pressure in the stokeholds was 4½ inches. Another important feature of the trials was that the *Viper* worked up from a speed of 14 knots to 36·585 knots in twenty minutes; almost as much importance is attached to this as to the high speeds attained, both being very valuable considerations in war vessels and cross channel boats. The trials, it is stated, worked without a hitch, and vibration was practically imperceptible in any part of the vessel.

ACCORDING to a writer in the *Times*, several earthquake shocks were felt at Bognor on July 18, between 10 and 11 p.m. Another correspondent suggests that they were merely the reports of the naval salute fired at Cherbourg on the departure of the French President at the times mentioned. The character of the disturbances, as described, certainly bears out this view. Similar movements and rumbling sounds were also observed at Torquay at the same time. Bognor is eighty-nine miles, and Torquay 101 miles, from Cherbourg.

THE Faculty of Sciences of the University of Rome proposes to publish by subscription a complete collection of the works of the late Prof. Eugenio Beltrami. The collection will probably extend to three or four large volumes of 2000 pages in all, and a copy will be sent to subscribers of 2*l.* and upwards. Subscriptions are to be sent to Isaia Sonzogno, secretary of the Scuola d'Applicazione per gli Ingegneri, 5, Piazza San Pietro in Vincoli, Rome.

IN a pamphlet, entitled the "Inidikil System," Mr. A. Lincoln Hyde suggests a decimal system of weights and measures for the English speaking people based on taking the inch as the fundamental unit. One of the author's main arguments for the proposal appears to be the failure of the metric system to obtain public favour in Great Britain and America, and he therefore thinks it desirable to make another attempt at decimalising our weights and measures.

IN the *Proceedings* of the Rochester Academy of Sciences, vol. iii. Brochure 2, Prof. Arthur L. Baker gives a general summary of vector analysis, and a short note on the graphic representation of imaginaries—both suitable for teaching purposes.

PART 13 of the *Rendiconti del R. Istituto Lombardo* contains two mathematical papers—one by Dr. Duilio Gigli, on helicoidal and ruled surfaces in elliptic space; the other by Signor U. Amaldi, on commutative linear substitutions. In the former, Dr. Gigli, starting with the classical methods of Beltrami, deduces certain theorems relating to ruled surfaces in space of constant curvature, exactly analogous to those known to exist in Euclidean space. The second paper deals with certain generalisations enunciated by Schlesinger in his note, "Ueber vertauschbare lineare Substitutionen" (Crelle, 1899), to which Amaldi applies certain synthetic methods due to Prof. Pincherle.

IN connection with the view that phosphorescence is due to movements of the ether determined by the vibrations of material particles, much interest attaches to the question as to whether the intensity of phosphorescence is modified by a magnetic field. Some experiments described by M. Alexandre de Hemptinne in the *Bulletin de la Classe des Sciences* (Brussels) appear to answer this question in the negative. In one experiment the phosphorescent substance was contained in a tube about 30 cm. long, placed between the poles of an electromagnet. The middle part of the tube was thus submitted to a field of about 30,000 C.G.S. units, while at the ends the magnetic force was comparatively feeble. The tube contained sulphide of calcium or of zinc, prepared after Becquerel's methods, and it was excited by being exposed to the sun. On observing the tube in a dark room it was seen to be uniformly phosphorescent throughout its length; it remained phosphorescent for a considerable time, and gradually the intensity diminished, but at no stage of the experiment was any difference of intensity noticeable from one end of the tube to the other. In order to make more exact observations, M. de Hemptinne constructed a phosphoroscope of sufficiently large dimensions to contain an electro-magnet. Although this method was much more sensitive than the preceding one, not the slightest difference could be observed in the behaviour of sulphide of lime, sulphide of zinc, nitrate of uranium, diamond and other more or less phosphorescent substances when submitted to a magnetic field of about 32,000 units.

HIGH summer temperatures have continued to prevail over the southern portion of our islands, but there has been an absence of the excessive heat which was experienced in the preceding week. Heavy thunderstorms occurred over a large part of England on July 27, resulting in a fairly heavy rain over London and smaller amounts in many parts of the country. Two quite separate storms passed over the metropolis, one in the afternoon and the second late in the evening. The lightning flashes were very frequent and unusually brilliant. At Greenwich, the rainfall accompanying the thunderstorms measured 0·84 inch, while in Westminster it only amounted to 0·42 inch. The weather has been generally cooler since the storms, although the thermometer in the south of England is well above the average. The mean temperature for July was 4° above the average at Greenwich; the mean of the maxima was 78°, and of the minima, or night readings, 57°. The total rainfall for the month at Greenwich was 1·41 inches, which is more than an inch less than the average.

A PAMPHLET on the organisation of the meteorological service in Japan has been published by the Tokio Observatory, for presentation to the Paris Exhibition. This service, which is very complete, consists of eighty stations of the first and second orders, and of about 900 stations at which only rainfall or temperature is recorded. The departmental stations, in accordance with the decree establishing the service, are established in suitable places, chosen by the Ministry of Public Instruction, and any persons wishing to establish additional stations have to obtain the authority of that Ministry. Electrical, earthquake, and other exceptional phenomena are regularly observed, in addition to the usual meteorological observations. All vessels belonging either to the imperial or merchant service, which are over 100 tons burden, are compelled to make observations at regular intervals, six times daily, and the logs are forwarded to the central observatory. There is also a regular service of weather telegraphy and storm warnings. The observations made three times daily are published in *Weather Reports*, together with forecasts for the following day. The average success of these forecasts amounts to 82 per cent., and of the storm warnings to 70 per cent. In addition to the *Daily Weather Report*, monthly and yearly bulletins are issued; these are naturally written in the Japanese language, but an English translation of the titles and important phrases is added. The present director of the service is Prof. K. Nakamura, graduate of the Tokio University; the staff and attendants of the central observatory amount to fifty-three in number.

THE ethnology of ancient history, deduced from records, monuments and coins, is a subject in which M. Charles de Ujfalvy has made some important investigations. In *l'Anthropologie*, tome ix., he has published a memoir on the White Huns. The Huns artificially deformed their heads so as to greatly increase their height (*déformation relevée* of Broca). They were nearly related to the Hoa of the Chinese annals (which name is merely the origin of the word Hun), to the Yé-tha of the Chinese (who must not be confounded with the very different Yué-tchi), and to the White Huns or Ephthalites of Byzantine and Armenian authors. The Hûna kings of India practised the same cranial deformation, as is shown by their effigies represented on their coinage. The Ephthalites practised polyandric customs, and their women wore special horned head dresses. Traces of polyandric habits, as well as of these extraordinary coiffures, are still to be met with, after more than twelve hundred years, in certain regions of the old Ephthalitic empire.

THE second part of vol. xxviii. of the *Morphologisches Jahrbuch* is entirely taken up by two profusely illustrated memoirs on the morphological anatomy of Vertebrates. In the first of these Dr. S. Paulli continues his elaborate investigations into the extent and form of the air-chambers in the mammalian skull; dealing in this section with the morphology of the ethmoid bone and the relations of the aforesaid chambers in Ungulates. Perhaps the most striking feature in this communication is the labour expended in working out the details of the labyrinth formed by the ethmoid and surrounding structures, as is well displayed in the text-figures, which resemble puzzles of an unusually complex type. Very unexpected is the discovery that the structure of the ethmoid divides the more typical Ungulates into two groups, one represented by the Ruminants and the other by the Suina and the Perissodactyla. As this grouping so completely traverses the classification indicated by other parts of the organisation, it may be that the feature in question is purely adaptive. In the general structure of the ethmoid the elephant resembles more typical Ungulates. The second of the above-mentioned memoirs is a continuation of Dr. B. Haller's study of the Vertebrate brain; the present section dealing with the Pond-Tortoise (*Emys orbicularis*). At the conclusion of his paper the author refers to the structural resemblances between the reptilian brain on the one hand and that of Monotremes and Marsupials on the other. He is led to conclude that a commissure connecting the hemispheres of the brain was developed in an extinct forerunner of the reptiles, which formed the ancestral type of both the Sauropsida and the Mammalia.

TWENTY years ago the late Dr. Dobson described a new species of Australian bat, remarkable for its white head and lower surface of the body, under the name of *Megaderma gigas*. From that time to this the species has been known solely by the type specimen—a male. In No. 7, vol. iii. of the *Records* of the Australian Museum, Mr. E. R. Waite describes a second example, this time a female, obtained in West Australia. To the same journal Mr. Waite likewise contributes a paper on additions to the fish-fauna of Lord Howe Island, in the course of which he describes four new species, one of them being assigned to a new genus. Several of them belong to the coral-eating Chætodonts. The author draws attention to the circumstance that since the transparent larval form to which the name Leptocephalus was assigned in 1763 is now ascertained to be the young of the Conger-eel, the generic title Conger has to give place to Leptocephalus. As this latter name is now no longer available for other similar larvæ of which the adults are unknown, he adopts for them the name Atopoichthys, lately proposed by Garman.

THE July number of the *Biologische Centralblatt* contains an interesting note by Dr. R. Stölzle on the position taken by K. E. von Baer with regard to the origin of the human race. Reference is made to von Baer's opposition to the doctrine of descent from lower animals (1) in pre-Darwinian times; (2) after the appearance of "The Origin of Species"; and (3) after the publication of "The Descent of Man."

CAPTAIN R. H. ELLIOTT, who has been for some time conducting researches into the nature and action of snake venom in India, arrives at the following conclusions in the *British Medical Journal*:—(1) The snakemen of South India are certainly ignorant of any method of producing in themselves a highly-developed condition of immunity. (2) Some few of them appear to practise the swallowing of venom, or the inunction of venom into their limbs, but it is doubtful if they do so with any well-defined object. It is possible that they thus obtain some degree of immunisation. (3) They confine themselves almost exclusively to the cobra, and escape harm by their intimate knowledge of the methods of handling this snake.

A COPY of the second edition of a catalogue of the fossils in the students' stratigraphical series of the Woodwardian Museum, Cambridge, by Mr. H. Woods, has been received.

THE plants collected on the Antillean cruise of the yacht *Utowana*, in Bermuda, Porto Rico, the Caymans, Cozumel, Yucatan, and the Alacran shoals, between December 1898 and March 1899, are described, under the title *Plantae Utowanae*, by Dr. Charles Frederick Millspaugh, in vol. ii. No. 1 of the botanical series of the Field Columbian Museum.

PROF. W. H. CORFIELD'S two Harveian lectures on disease and defective house sanitation have been translated into Hungarian by Dr. Frank, of Budapest, for the Royal Society of Public Health of Hungary. Dr. Frank remarks in the preface that the lectures "merit the attention of Hungarian readers because they explain the views of a prominent English hygienist, and also because the sanitary arrangements of dwellings in Hungary are much more unsatisfactory than those in England."

THE additions to the Zoological Society's Gardens during the past week include a White-fronted Capuchin (*Cebus hypoleucus*) from Central America, presented by Mr. W. H. Laws; a Two-spotted Paradoxure (*Naudinia binotata*) from West Africa, presented by Mr. Robert H. Gush; a Levaillant's Amazon (*Chrysotis levaillanti*) from Mexico, four Lorikeets (*Trichoglossus rubritorques*) from North-west Australia, six Roofed Terrapins (*Kachuga tectum*) from British India, two Alligator Terrapins (*Chelydra serpentina*), an American Box Tortoise (*Cistudo carolina*), a Sculptured Terrapin (*Clemmys insculpta*) from North America, deposited; two —— Buntings (*Emberiza sulphurata*) from Japan, purchased; an Altai Deer (*Cervus eustephanus*), three Crested Pigeons (*Ocyphaps lophotes*), a Spotted Pigeon (*Columba maculosa*), four Vinaceous Turtle Doves (*Turtur vinaceus*), bred in the Gardens.

## OUR ASTRONOMICAL COLUMN.

COMET BORRELLY BROOKS, 1900 *b*.—Several telegrams received from the *Centralstelle* at Kiel announce the appearance of a new comet in the constellation Aries. The following are the positions given:—

| 1900 | R.A. h. m. s. | Decl. | Observer. |
|---|---|---|---|
| July 23d. 12h. 50·0m. (Marseilles Mean Time) | ... 2 43 33 | ... +11° 51′ | ... Borrelly. |
| July 23d. 13·00h. (Geneva Mean Time) | ... 2 43 40 | ... +12° 30′ | ... Brooks. |
| July 24d. 12h. 57·1m. (Strassburg Mean Time) | ... 2 44 26 | ... +14° 32′ 42″ | ... Kobold. |

A later circular from Kiel furnishes an ephemeris for further observations of the comet, prepared by Herr J. Möller from measures of July 24, 25 and 26.

*Elements.*

$T =$ 1900 Aug. 3, 298. Berlin Mean Time.

$$\left.\begin{array}{l} \omega = \phantom{3}12^{\circ}\ 30'{\cdot}2 \\ \Omega = 328\ \phantom{0}1{\cdot}8 \\ \iota = \phantom{3}62\ 35{\cdot}6 \end{array}\right\} 1900{\cdot}0.$$

$\log q = 0{\cdot}00636$

CATALOGUE OF DOUBLE STARS.—The *first* volume (1900) of the *Publications of the Yerkes Observatory* of the University of Chicago has recently been distributed; it contains a list of 1290 double stars, discovered from 1871–1899 by Prof. S. W. Burnham, now on the staff of the Yerkes Observatory. The majority of the measures have hitherto only been published in sections, comprising portions of nineteen different catalogues, and the work of bringing so large a mass of material together was commenced during the author's connection with the Lick Observatory (1888–1892). While working with the large instrument there, many of the more difficult pairs were re-measured, and their positions carefully re-determined by comparison with the newer star catalogues of the *Astronomischen Gesellschaft*, Cordoba, &c., instead of those of Lalande and Argelander. As, however, in the present work no attempt has been made to supersede other star catalogues with respect to the absolute positions, it has not been thought worth while to bring the co-ordinates past the epoch 1880.

Commencing astronomical observations in 1861 with a very small instrument, Prof. Burnham obtained a six-inch equatorial from Alvan Clark in 1869, with which he commenced systematic work on double stars in 1872. Since that time his observations have been made with instruments of varying aperture, 9·4, 12, 15·5, 16, 18·5, 26, 36 and 40 inches respectively.

Especially interesting is the fact that a great proportion of the pairs discovered have been found to be physically binary, and that these are generally closer and more difficult to measure compared with those in slower motion.

A special list of quadruple stars is given, and various measures have been obtained by the co-operation of other observers with different instrumental equipment. The stars are arranged in order of right ascension; and besides the present elements, a short description of special particulars with comparative previous measures are added to each where necessary, and several illustrations are given of the instruments used in the course of the work.

## SOME RESULTS OBTAINED WITH A STORAGE BATTERY OF TWENTY THOUSAND CELLS.[1]

THE remarkable development of practical employments of electricity have put the professor of physics at a disadvantage, compared with the electrical engineer. The latter has at his service thousands of electrical horse-power, while the college instructor can barely obtain fifty. The engineer can experiment with enormously strong currents and study their effects in chemical industries, and in the production of intense heat. Thus the study of the manifestations of electricity on a great scale seems to be relegated to the electrical engineer.

There is one direction, however, in which the university professor can enter into competition with the engineer and even surpass him in resources. This direction is in the field of high electromotive force; and I wish to call your attention to some results which I have obtained with a storage battery of twenty thousand cells. For several years I have had at my command ten thousand cells; and the plant has proved so practical that I resolved last autumn to double the number of cells. The battery is now finished, and you will have an opportunity of seeing its manifestations.

With twenty thousand cells of the Planté type I can obtain forty-two thousand volts, and by the use of Leyden jars I can step up to three million. I cannot go higher, for the very interesting reason that air at atmospheric pressure becomes a fairly good conductor beyond two million volts, and it is impossible to charge Leyden jars to this potential, or to produce sparks in a laboratory of greater length than seven feet. To obtain the greatest manifestations of three million volts, it would be necessary to put the apparatus in an open field at least thirty feet from the ground, and remote from all other objects. Jars and circuits charged to this high voltage emit a luminous discharge to the floor of the room and to the brick walls, and indicate by this inductive discharge the presence of steam pipes twenty feet distant. The air breaks down quickly under this powerful electric stress, and, indeed, acts like a rarified gas.

Nevertheless discharges of electricity six and seven feet long are of interest, especially to many of you who are citizens of Boston, where Benjamin Franklin was born. These discharges closely resemble lightning, and one can reproduce all the photographic effects obtained by students of this astounding natural phenomenon. I have discovered the interesting fact that these long sparks are oscillatory.

The method of proof is this: I connected the condensers which were used in series to produce the high potential of three million volts, in multiple with a known self-induction. The discharge was then photographed. Here is one of the results: The distance between these bead-like figures from centre to centre represents one five-thousandth of a second (Fig 1). When the condensers are connected in series through the same self-induction the discharge still remains oscillatory, but of a much higher period; we are sure of this fact from Lord Kelvin's discussion of the limits of oscillatory action. You will perceive from Fig. 1 that I have been able, by means of the large battery and the large condenser, to photograph comparatively slow oscillations. I have lately succeeded in obtaining photographs of oscillations eight hundred a second; and experiments on the permeability of iron wire with powerful discharges with such low periods are now in progress.

That most discharges of lightning are to-and-fro, or oscillatory, I feel sure, and I have outlined my method of proof; but this was hardly necessary, for the photographs of the long sparks show on mere inspection the to-and-fro motion, for on the line of discharge forks can be observed pointing in opposite directions, showing that the discharge changed from positive to negative. These forks, or branching discharges, have an interesting peculiarity, which was brought out in the following manner. A sheet of plate glass about five feet square was placed between the terminals of the high potential apparatus, and a minute hole was bored in the middle of this plate.

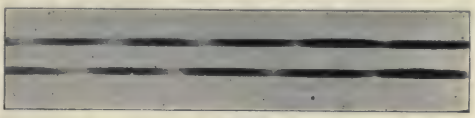

FIG. 1.]

This hole could be made very small by plugging the orifice with paraffin, and making needle-holes in the paraffin. When the spark terminals were opposite the hole, each a foot and a-half from it, the spark sought the hole. A photograph of the spark (Fig. 2) shows an apparent breadth of spark much greater than the diameter of the hole; indeed, the minute size of the latter cannot be reproduced on the negative; while the spark seems to the eye to be an eighth of an inch in thickness, and actually measures about a millimetre in diameter on the negative. The reason of this phenomenon, I believe, is that only a portion of the discharge passes through the hole. This can be shown in the following manner. The terminals were not placed opposite the hole, but to one side of it, about a foot from it, and about half a foot from the glass. The discharge then jumped to the glass (Fig. 3), and pursued a devious way to the hole. When the hole was completely filled with paraffin the spark still jumped to the glass, apparently piercing a hole through it; but this was impossible, for the thickness prevented this. The discharge was continued evidently by an inductive action. I next restored the orifice, and, keeping the spark terminals in the last position referred to, I hung a large sheet of paraffined paper

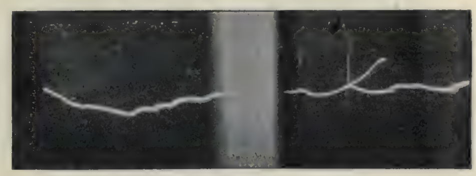

FIG. 2.

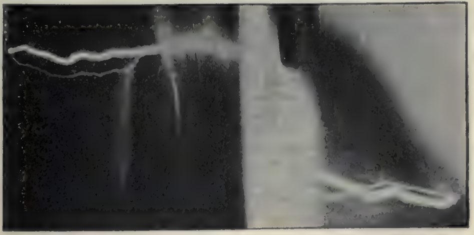

FIG. 3

---

[1] Paper read by Prof. John Trowbridge at a meeting of the American Academy of Arts and Sciences, held in the Jefferson Physical Laboratory, Harvard University, Cambridge, U.S.

on the glass, and a photograph of the spark was taken. It was found that an explosion occurred at each change in direction of the spark, or at each fork in it. The two effects are shown in Fig. 4 and Fig. 5; and you will see that even the sinuosities are reproduced by a rent in the paper. In the case of a thunderstorm, may not the peculiar rolling of the thunder be due to the successive explosions along the path of a single discharge some hundreds of feet apart?

But I will not dwell longer upon the fascinating study of lightning in a laboratory; for I wish to call your attention to larger fields of inquiry which the possession of this great battery opens. One of the most promising is that of spectrum analysis. In connection with the battery I have three hundred glass plate condensers, one-eighth of an inch thick, and about ten by eighteen inches coated surface; this condenser is charged in multiple to a potential of twenty thousand volts. The glass of the thickness of one-eighth of an inch stands this stress; but I can not use my full voltage of forty thousand, for the glass plates are immediately pierced. To utilise this voltage it will be necessary to employ plates a quarter of an inch in thickness. This is an interesting proof of the large surface density furnished by the battery. The noise of the discharge from this condenser is like the report of a pistol.

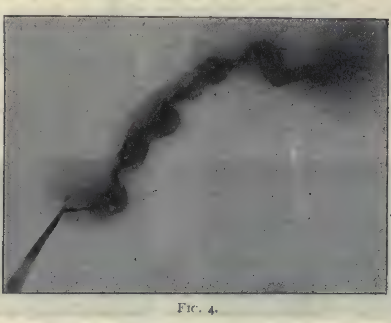

FIG. 4.

FIG 5.

Here is an example of its great heating effect. An iron wire was stretched across the spark terminals. This was deflagrated (Fig. 6), while at the same time a spark passed between the terminals. The surrounding air was filled with the scintillating sparks of iron. This shows that it is not impossible that sparks may be formed inside a metallic cage or enclosure; for we can conceive of such an enclosure as a multiple circuit around a spark gap.

By means of the discharge of these condensers charged to a difference of potential of forty thousand volts, I can produce probably the highest degree of instantaneous temperature which has been reached. I have been obtaining instantaneous photographs of the spectra of gases and of the vapour of metals. One discharge, with a Browning direct vision spectroscope, will give a photograph of the spectra of hydrogen, and ten or twelve discharges are sufficient when a short focus grating is employed with a fairly fine slit. I find it desirable to use a peculiar end-on tube for the study of hydrogen. It is of the nature of a Crookes' tube, one end being blown into a very thin bulb; this tube can be heated to a very high temperature during the process of exhaustion to drive out the water vapour.

I have thus submitted hydrogen to a higher temperature than it has been possible to reach before, and the study of the spectra promises to have a bearing on stellar spectra. The advantage of an intense source of light, and consequently of a short time of exposure, is very great; for a large amount of fog is thus escaped, and faint lines come out which escape observation by the comparatively long exposures hitherto necessary.

There is another direction in which this battery can be used, which promises to be of importance in surgery. It furnishes a new source of the X-rays.

The greatest need in the scientific study, and also in the employment of the X-rays in surgery, is a steady source of them. All the methods now in use give a light which is far from constant; the electrical impulses which produce the rays are unequal in strength, and even when they are equal they are generally alternating in character. This to-and-fro action tends to produce a blurring of the shadows, for fluctuating electrical impulses sent through an X-ray tube are apt to give a shifting radiant point.

The ideal method of producing the rays is by the employment of a large storage battery, and I have been working toward this much-desired end during the past two years.

Traces of the X-rays can be obtained with a steady current at a voltage of five thousand; and they are strongly produced at twenty thousand. When forty thousand volts are used with a steady current, the exhibition of rays is surprising; a fluorescent screen is lighted with extreme brilliancy, and marvellous shadows of the bones of the hand are obtained. A steady current is undoubtedly the ideal current for the production of the X-rays; for the radiant point of the rays does not fluctuate, and there is no to-and-fro or oscillatory motion which tends to produce what may be called X-rays ghosts. It is well known that these ghosts are often puzzling to the surgeon.

FIG. 6.

In my experiments I was surprised at the small amount of current necessary with a voltage of forty thousand to produce a strong development of the X-rays. The use of ten milliamperes was dangerous to the tube; the anode grew white hot, and the Crookes' tube resembled an enclosed arc lamp. It was interesting also to notice that the usual fluorescence ceased to be noticeable; and although the tube was of a milky white hue, the X-rays were extraordinarily brilliant. In my first experiments the fall of resistance in the tube was so rapid that the anti-kathode was melted. In the case of all the tubes with which I have experimented, the fall in resistance advances very rapidly with the degree of reddening of the anti-kathode. When this becomes red, or when a red spot appears on it, the difference of potential between the terminals of the tube does not in general exceed twenty thousand volts.

It would seem therefore uneconomical to continue the use of a high potential machine when this critical point is reached. At this point, moreover, the rays seem to be given off most vigorously, and at this stage a quantity machine giving a comparatively small voltage could be substituted to advantage for a coil or other apparatus giving six to eight inch sparks. A large storage battery makes it possible to regulate the strength of the current which is at any moment exciting the tube. I accomplish this at present by means of a liquid resistance, which enables me to graduate the strength of the current to any extent. This advantage is a very great one, and is not possessed by any other method. It seems possible, by carefully regulating the strength of the current and the voltage, to obtain photographs of the tendons, and possibly the muscles; for the photographs which I have already obtained show great contrasts, and there are indications of muscular layers and tendons. The contrast between the bones and the flesh is extraordinary, much greater than in the X-ray pictures usually obtained by the Rhumkorf coil.

The investigator, by means of the liquid resistance, can keep the tube at the same point of excitation. For the scientific study of the X-rays nothing seems better adapted than this large battery plant which I have had constructed, and it is not impossible that a smaller plant of the same number of cells, but with less capacity, may be desirable for large hospitals.

The first step in an investigation of the X-rays is to obtain a steady source of these rays: one of the essentials for the accomplishment of this is a steady current which can be regulated. This, I believe, I have secured. The next step will be the proper control of the amount of gas in the tube. At one time I believed that an oscillatory discharge was necessary for the strongest manifestation of the rays. My experiments, however, with a steady current have shown me that an oscillatory discharge is not essential; such a discharge could not take place through the large resistance which I used—4,000,000 ohms. Such are some of the results which can be obtained by the use of this large battery.

---

## THE CRUISE AND DEEP-SEA EXPLORATION OF THE "SIBOGA" IN THE INDIAN ARCHIPELAGO.

THE annual summer meeting of the Netherlands Zoological Society, which was held in Amsterdam on July 1, was of more than usual interest on account of the fact that it was attended by all the members of the scientific staff of the *Siboga* expedition, who returned only a few weeks before from their one year's cruise in the different basins of the Indian Archipelago, during which they covered a distance of about 12,000 sea miles, *i.e.* about half the circumference of the globe. The track, as indicated on the accompanying Fig. 1, commenced at Soerabaja on March 7, 1899; it ended in the same port on February 27, 1900. The vessel, which is a cruiser belonging to the Dutch Royal Navy, was on its first trip, and before its departure was specially fitted up for the work of the cruise, both with a sounding apparatus of Le Blanc and of Lucas, with some 20 kilometres of wire rope for dredging purposes, and with all modern appliances for pelagic fishing, for plankton collection and for deep-sea work (a "sondeur à clef" of the Prince of Monaco, apparatus for obtaining sea-water from given depths according to Petterson and Sigsbee, Hensen's nets, &c.)

It may here be mentioned that very thorough experiments were made with Mr. G. H. Fowler's net, which is specially intended for plankton from given depths, and which can be opened and shut at will at any moment. About this net, which is of very recent invention, and which has as yet only been used by Mr. Fowler himself, and perhaps on board the *Valdivia*, the members of the *Siboga* expedition are very enthusiastic. It is most trustworthy in its results and fruitful in its catches.

The leader of the *Siboga* expedition, Prof. Max Weber of Amsterdam, well-known by his former expeditions to the East Indies, to the far north and to South Africa, was accompanied by Madame Weber-van Bosse, herself an accomplished naturalist, who made a very complete collection of Algæ during the cruise, and who settled three very important points as a result of the observations made, viz.: (1) the presence in unexpected quantities of calcareous Algæ (Lithothamnion) in the Archipelago, so that they build up reefs of considerable dimensions, in depths of 3 to 40 metres, in one case even at 120 metres. Different circumstances of level, current, &c., must co-operate to render the occurrence of Lithothamnion in such quantities possible: the expedition found them realised in at least thirty different localities, and henceforth the possible contribution of Lithothamnion-remains to the formation of the earth's crust will in many cases have to be reconsidered by the geologists. (2) The presence of a minute vegetal organism about which of late years English and German naturalists have considerably differed in opinion: the Coccosphære. Neither the members of the German Plankton nor those of the *Valdivia* expedition have succeeded in satisfying themselves that these miniature spheres with adherent discs of lime, already known in the Cretaceous period and everywhere present on the bottom of the sea, are organisms and not inorganic concretions or sediments. Mme. Weber has now succeeded in demonstrating the truth of the contrary, and has found this very lowly organised alga in great abundance, and entirely agrees with Mr. George Murray's statements concerning the alga-nature of the coccospheres; she has even found in this alga green chromatophores, and has seen phases of division of the spheres; (3) the presence of shell- and rock-perforating algæ, a group hitherto neglected in the tropics, of which she has brought home a great number.

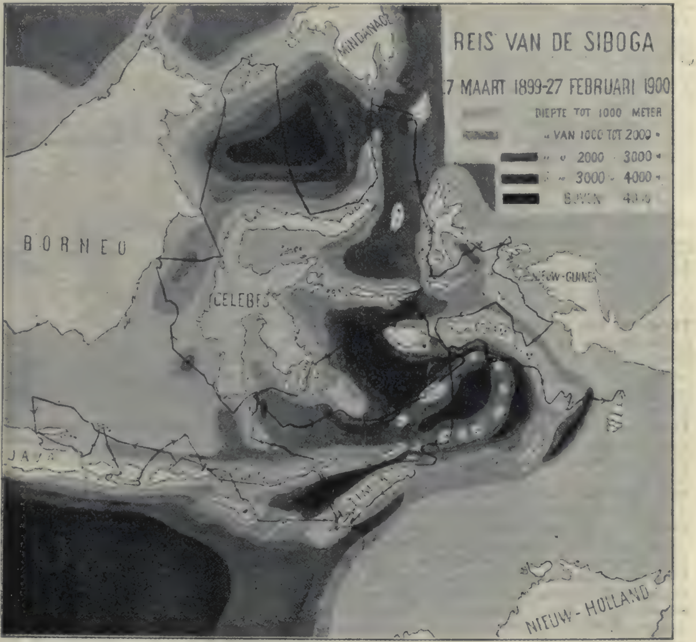

FIG. 1.—Track of the *Siboga*.

The zoological collections of the *Siboga* are very extensive, both those collected on the coral-reefs and from the very different depths. Deep-sea animals were met with at depths of about 150 fathoms, where they would hardly have been expected, but where their presence is explained by certain hydrographical circumstances to be mentioned later. Porifera, and among them the most diverse Hexactinellids, were exceedingly numerous. East of the Aru Islands, gigantic specimens of Adeona were captured. This curious Bryozoarian, of leaf-like shape and attached to a segmented stem, has sometimes been considered as one of the Isidinæ.

Of the curious solitary Alcyonarians, the Haimeidæ, which up to now are known as small specimens from the Red Sea and from Algiers, a species of a very considerable size has been met with. Amphianthus, an absolutely flat Actinian, was found on the shell of a Dentalium, and amongst the numerous Echinoderm-finds material abounds to definitely settle the question about the regeneration and the so-called comet forms of Linckia. It could be demonstrated that the regeneration takes place, without any part of the disc being preserved, from a bare arm-fragment. On these Linckias the parasitical molluscs, Thyca and Stylifer, were often present. Various Solenogastres were captured, and many interesting Cephalopods. The fish collection is also very considerable, and a great many deep-sea forms are among them, of which a specimen of Ruvettus attains to a size of several feet.

The most beautifully transparent larval Murænas were at the other end of the scale, and were also exhibited at the meeting. Both they and other pelagic organisms, Medusæ, Heteropods, &c., were most successfully preserved in formalin. On the whole the preservation of all the specimens, for which the most various methods were employed, is first-rate; and Mr. Nierstrasz, to whose supervision this had been more especially entrusted, received due recognition of his merits on this head. Some hundred bottles of plankton have yet to be sorted and worked out. Dr. Versluys communicated to the meeting the results of investigations into the amount of oxygen contained in the sea-water at different points which he had made during the cruise, and Prof. Weber called attention to certain hydrographical results of primary importance obtained by the expedition.

The gist of these is that the communication between the deep water of the Indian and Pacific Oceans and that of the Archipelagan basins is very different from what it was expected to be. The different straits between the lesser Sunda Islands, Bali to Flores, are none of them deep enough to allow of any horizontal passage of the deeper and colder strata (where the temperature is 0·9° C.) into the Banda basin and its continuations between Flores and Timor and between Flores and Celebes. These undoubtedly receive their cold bottom-water from the Pacific Ocean by way of the deep communications indicated on the map to the north of Buru (the so-called Ceram sea), which opens out into the Pacific by a narrow passage (the so-called Moluccan passage). In the deep spurs, to which the name of Bali and Flores sea may be given, the expedition could actually demonstrate the existence of a bottom-current which flows westward and which brings the cold water from the Banda sea into these recesses where the supply from the Indian Ocean through the numerous straits is only superficial and restricted to surface-water of a temperature of more than 12° C. The cold bottom-current of 3° C. just alluded to, which slowly flows westward out of the Banda sea, even rises up along the sloping coasts of the Kangeang-Paternoster-Postillon islands (not indicated on the map) situated north of this deep sea spur, as could be demonstrated both by serial temperatures and even by the net, which, as mentioned above, brought up deep-sea forms from comparatively shallow water, just because of this bottom current, which, being hemmed in, flows towards the surface.

The temperature of 3° C. referred to above is the uniform minimum temperature for the whole of the Banda basin below the depth of 1600 m., and the theoretical conclusion that no deeper communications than this exist with either of the Oceans was practically verified, and also (as indicated above) that the cold water of the greater depths comes from the Pacific and not from the Indian Ocean.

The Banda Sea, *sensu strictiori*, was further found to be different from what was hitherto held. On charts, mention is made of a depth of 7000 metres (4000 fathoms) in the neighbourhood of Banda. This depth has been demonstrated by the *Siboga* to be due to some error, the depth being nowhere below 5500 metres, and the basin itself being most unexpectedly intersected by two shallow ridges, clearly visible on the map, the more westward of which has been named the Siboga Ridge. Geological speculations concerning this part of the earth's crust will undoubtedly be influenced by these results.

For the distribution of deep-sea animals, the difference of a couple of degrees between the bottom-water of these basins and that of the oceans will certainly not have much importance; and even the ridges will in the long run prevent only very few deep-sea animals from penetrating into the basins in the course of generations, when the difference of pressure can be slowly neutralised. At all events, the catches did not justify expectations that these enclosed deep basins might harbour a deep-sea fauna which, by its isolation from the ocean, had developed into peculiar local deep-sea faunas particular to those basins.

The hydrographical work of the expedition has thus been of very considerable importance, and will soon be also noticeable in improved navigating charts for the regions explored. Even geographical corrections of considerable amount are amongst the results of the cruise. The south coast of the large island of Timor (of which the eastern half is a Portuguese, the western a Dutch possession) will have to undergo a radical alteration, as indicated on the accompanying sketch (Fig. 2). Thus the *Siboga* expedition has not inconsiderably reduced the colonial surface area of Portugal, having anchored in spots which, according to the present maps, lie far inland.

The expedition can thus be complimented on having achieved a most successful piece of work, and it is undoubtedly in the first place due to the undaunted energy of the leader, Prof. Weber, and to the exemplary skill of the officer in command of the vessel, Comm. Tydeman, who for many years has already been one of the leading hydrographers in the Archipelago. The liberality of the Naval Department, and its active co-operation in all that pertained to the expedition, have been especially noticeable.

The results, both hydrographical, botanical, zoological and geological, will, as soon as possible, be worked out by different specialists, and be brought together in a series of well-illustrated quarto volumes, the number of which is roughly estimated at about fifteen. Several specialists, both Dutch and foreign, have already promised to co-operate, and what with Alcock's researches in the Bay of Bengal, the *Valdivia's* exploration of the Indian Ocean, the Australian investigations of the Barrier Reef and the Torres Straits, the Belgian Antarctic expedition, and Agassiz's dredging expeditions in the Pacific, we can safely say that, by the time this publication will have appeared, we will have obtained a very thorough knowledge of an important portion of the abyssal regions, towards the exploration of which the *Lightning*, *Porcupine* and *Challenger* have set the example, and the *Blake*, *Albatross*, *Travailleur*, *Talisman*, *Gazelle*, *Vettor Pisani*, *Willem Barents*, *Hirondelle* and *Princesse Alice* have so considerably contributed from other parts of the globe.

A. A. W. H.

## EXPERIMENTATION ON EMOTION.

OF points where physiology and psychology touch, the place of one lies at the phenomenon "emotion." Built upon sense-feeling much as cognition is built upon sense-perception, emotion may be regarded almost *as* a "feeling"—a "feeling" excited, not by a simple unelaborated sensation, but by a group or train of ideas. To such compound ideas it holds relation much as does "feeling" to certain species of simple sense-perceptions. It has a special physiological interest in that certain visceral reactions are peculiarly concomitant with it. Heart, blood-vessels, respiratory muscles and secretory glands play special and characteristic *rôles* in the various emotions. These viscera, though otherwise remote from the general play of psychical process, are affected vividly by the emotional. Hence many a picturesque metaphor of proverb and phrase and name—"the heart is better than the head," anger "swells within the breast," "Richard Cœur de Lion." It was Descartes who first relegated the emotions to the brain. Even this century Bichat wrote, "The brain is the seat of cognition, and is never affected by the emotions, whose sole seat lies in the viscera." But brain is now admittedly a factor necessary in all higher animal forms to every mechanism whose working has consciousness adjunct.

What is the meaning of the intimate linkage of visceral actions to psychical states emotional? To the ordinary day's consciousness of the healthy individual the life of the viscera contributes little at all, except under emotion. The perceptions of the normal consciousness are rather those of outlook upon the circumambent universe than inlook into the microcosm of the "material me." Yet heightened beating of the heart, blanching or flushing of the blood-vessels, the pallor of fear, the blush of shame, the Rabelaisian effect of fright upon the bowel, the action of the lacrymal gland in grief, all these are prominent characters in the pantomime of natural emotion. Visceral disturbance is evidently a part of the corporeal expression of emotion. The explanation is a particular case in that of movements of expression in general. The hypothesis of Evolution afforded a new vantage point for study of that question. Fixed bodily expressions of emotion are hereditary. They are, especially in the "coarser or animal emotions," largely common to man and higher animals. The point of view is exemplified by Darwin's argument concerning the contraction of the muscles round the eyes during screaming. "Children when wanting food or suffering in any way cry out loudly like the young of most animals, partly as a call to their parents for aid, and partly from any great exertion serving as relief. Prolonged screaming inevitably leads to the engorging of the blood-vessels of the eye; and this will have led at first consciously and at last habitually to the contraction of the muscles round the eyes in order to protect them." Mr. Spencer writes: "Fear, when strong, expresses itself in cries, in efforts to hide or escape, in palpitations and tremblings; and these are just the manifestations which would accompany an actual experience of the evil feared. The destructive passions are shown in a general tension of the muscular system, in gnashing of the teeth and protrusion of the claws, in dilated eyes and nostrils, in growls: and these are weaker forms of the actions that accompany the killing of prey." In a word, expression of emotion is instinctive action.

Movement of expression, be it facial or vocal, let it involve the skeletal or the visceral musculature, must have an explanation the same in kind as that of other instinctive movement. To enter upon its "why" is to enter upon the "why" of instinct. Suffice it to say here that if we follow the doctrine of evolution we cannot admit any absolute break between man and brute even in the matter of mental endowment. The instinctive bodily expressions of emotion probably arose as attitudes useful in the animal's environment for defence, escape, seizure, embrace, &c. These as survivals have become symbolic for states of mind. Hence the intelligible nexus between the muscular attitude, the pose of feature, &c., and the emotional state of mind. But between action of the viscera and the psychical state the nexus is less obviously explicable. This latter connection adds a difficult corollary to the general problem.

The fact of the connection is on all hands admitted, but as to the manner of it opinion is at issue. Does (1) the psychical part of the emotion arise and its correlate nervous action then excite the viscera? Or (2) does the same stimulus which excites the mind excite concurrently and *per se* the nervous centres ruling the viscera? Or (3) does the stimulus which is the exciting cause of the emotion act first on the nervous centres ruling the viscera, and their action then generate visceral sensations; and do these latter, laden with affective quality as we know they will be, induce the emotion of the mind? On the first of the three hypotheses the visceral reaction will be secondary to the psychical, on the second the two will be collateral and concurrent, on the third the psychical process will be secondary to the visceral.

To examine the last supposition first. It is a view which in recent years has won notable adherents. Prof. William James writes: "Our natural way of thinking about these coarser emotions (*e.g.* "grief, fear, rage, love") is that the mental perception of some fact excites the mental affection called the emotion, and that this latter state of mind gives rise to the bodily expression. My theory, on the contrary, is that *the bodily changes follow directly the perception of the exciting fact, and that our feeling of the same changes as they occur* IS *the emotion.*" "*Every one of the bodily changes, whatsoever it be, is* FELT, *acutely or obscurely, the moment it occurs.* If the reader has never paid attention to this matter, he will be both interested and astonished to learn how many different local bodily feelings he can detect in himself as characteristic of his various emotional moods." "If we fancy some strong emotion and then try to abstract from our consciousness of it all the feelings of its bodily symptoms we find we have nothing left behind, no "mind-stuff" out of which the emotion can be constituted, and that a cold and neutral state of intellectual perception is all that remains." "If I were to become corporeally anæsthetic, I should be excluded from the life of the affections, harsh and tender alike, and drag out an existence of merely cognitive or intellectual form."

Prof. Lange traces the whole psycho-physiology of emotion to certain excitations of the vasomotor centre. For him, as for Prof. James, the emotion is the outcome and not the cause or the concomitant of the organic reaction; but for him the foundation and corner-stone of the organic reaction is as to physiological quality vascular, namely, vasomotor. Emotion is an outcome of vasomotor reaction to stimuli of a particular kind. This stimulus induces a vasomotor action in viscera, skin, and brain. The change thus induced in the circulatory condition of these organs induces changes in the actions of the organs themselves, and these latter changes evoke sensations which constitute the essential part of emotion. It is by excitation of the vasomotor centre, therefore, that the exciting cause, whatever it chance to be, of emotion produces the organic phenomena which as felt constitute for Lange the whole essence of emotion. The teaching of Prof. Sergi closely approximates to that of Lange.

The views of James, Lange, and Sergi have common to them this, that the psychical process of emotion is secondary to a discharge of nervous impulses into the vascular and visceral organs of the body suddenly excited by certain peculiar stimuli, and that it depends upon the reaction of those organs. Prof. James's position in the matter is, however, not wholly like that of Prof. Lange. In the first place, he does not consider vasomotor reaction to be primary to all the other organic and visceral disturbances that carry in their train the psychological appanage of emotion; and Prof. Sergi, though more nearly in harmony with Lange, agrees with James in this. In the second place, Prof. James seems to distinctly include other "motor" sensations and centripetal impulses from musculature other than visceral and vascular, among those which causally contribute to emotion. Thirdly, he urges his theory as one completely competent only for the "coarser" emotions, among which he instances "fear, anger, love, grief." For Lange and Sergi the basis of apparition of all feeling and emotion is physiological, visceral, and organic, and has seat for the former authority exclusively, and for the latter eminently, in the vasomotor system.

To obtain some test of this view is not difficult by experiment. Appropriate spinal and vagal transection removes completely and immediately the sensation of all the viscera and of all the skin and muscles below the shoulder (see Fig. 1 on p. 330). The procedure at the same time cuts from connection with the organs of consciousness the whole of the circulatory apparatus of the body. I have had under observation dogs in which this had been carried out. I will cite an animal selected because of markedly emotional temperament. Affectionate toward the laboratory attendants, one of whom had her in charge, toward some persons and toward several inmates of the animal house she frequently showed violent anger. Her ebullitions of rage were sudden. Their expression accorded with a description furnished by Darwin. Besides the utterance of the growl, "the ears are pressed closely backwards, and the upper lip is retracted out of the way of the teeth, especially of the canines." The mouth was slightly opened and lifted; the eyelids widely parted; the pupils dilated. The hair along the mid-dorsum, from close behind the head to a point more than half way down the trunk, became rough and bristling.

The reduction of the field of sensation in this animal by the procedure above-mentioned produced no obvious diminution or change of her emotional character. Her anger, her joy, her disgust, and when provocation arose her fear remained as evident as ever. Her joy at the approach or notice of the attendant, her rage at the intrusion of a cat with which she was unfriendly, remained as active and thorough. But among the signs expressive of rage the bristling of the coat along the back no longer occurred. On the other hand, the eyes were well opened, and the pupil distinctly dilated in the paroxysm of anger. Since the brain had been by the transection shut out from discharging impulses *via* the cervical sympathetic the dilatation of pupil must have occurred by inhibition of the action of the oculomotor centre.

The coming of a visitor whose advent months before had elicited violent anger, again provoked an exhibition of wrath significant as ever. The expression was that of aggressive rage. The animal followed each movement of the stranger as though of an opponent, growling viciously. A cat with which she was never friendly, and a monkey new to the laboratory, approaching too near the kennel, excited similar ebullitions. No doubt was left in our minds that sudden attacks of violent anger were still easily excited. But she also gave evidence daily that she had the accession of joyous pleasure and delight she had always shown at the approach of the attendant the first thing of a morning, or at feeding time, or when caressed by him, or encouraged by his voice.

Few dogs even when very hungry can be prevailed on to touch dog's-flesh as food. Almost all turn from it with signs of repugnance and dislike. I had strictly refrained from testing this animal previously with regard to disgust at dog's-flesh offered in her food. Flesh was given her daily in a bowl of milk, and this she took with relish. The meat was cut into pieces rather larger than the lumps of sugar usual for the breakfast table. It was generally horse-flesh, sometimes oxflesh. We proceeded to the observation thus: the bowl was placed by the attendant in the corner of the stall, with milk and meat in every way as usual; but the meat was flesh from a dog killed on the previous day. Our animal eagerly drew itself toward the food; it had seen the other dogs fed, and evidently itself was hungry. Its muzzle had almost dipped into the milk before it suddenly seemed to find something there amiss. It hesitated, moved its muzzle about above the milk, made a venture to take a piece of the meat, but before actually seizing it stopped short and withdrew again from it. Finally, after some further examination of the contents of the bowl (it usually commenced by taking out and eating the pieces of meat), without touching them, the creature turned away from the bowl and withdrew itself to the opposite side of the cage. Some minutes later, in result of encouragement from us to try the food again, it returned to the bowl. The same hesitant display of conflicting desire and disgust was once more gone through. The bowl was then removed by the attendant, emptied, washed, and horseflesh similarly prepared and placed in a fresh quantity of milk was offered in it to the animal. The animal once more drew itself toward the bowl, and this time began to eat the meat, soon emptying the dish. To press the flesh upon our animal was of no real avail on any occasion; the coaxing only succeeded in getting her to, as it were, re-examine but not to touch the morsels. The impression made on all of us by the dog's behaviour was that something in the dog's-flesh was repulsive to her, and excited disgust unconquerable by ordinary hunger. Some odour attaching to the flesh seemed the source of its recognition.

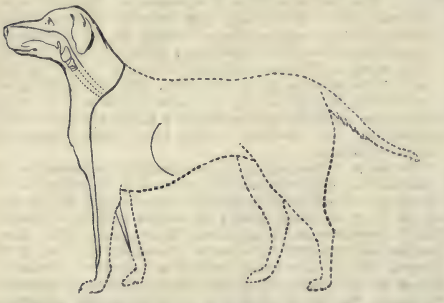

FIG. 1.—Diagram showing the great reduction of the field of sentivity. The head and neck and the diaphragm muscle (indicated by the curved line behind the chest) are practically the only parts left sensitive. The remainder of the body and the limbs, as well as the digestive and respiratory organs behind the throat, and the whole of the circulatory and other organs, are entirely cut off from making any contribution to consciousness.

Fear appeared clearly elicitable. The attendant, approaching from another room of which the door was open, chid the dog in high scolding tones. The creature's head sank, her gaze turned away from her advancing master, and her face seemed to betray dejection and anxiety. The respiration became unquiet, but the pulse never changed its rate.

In the face of these observations the vasomotor theory of the production of emotion becomes, I think, untenable: also that visceral sensations or presentations are *necessary* to emotion. A mere remnant of all the non-projecting or affective senses was left, and yet emotion persisted. If I understand it aright, Prof. James and Lange's theory lays stress on organic and visceral presentations, but re-presentations of the same species might no doubt be put forward in their place. That would be a somewhat different matter. To exclude the latter hypothesis, the deprivation of vascular and organic sensation might have to date from a very early period of the individual life. Experience early acquires its emotional data. If after that all fresh presentation were precluded, re-presentation might still be possible on the basis of already gained experience. But it is noteworthy that one of the dogs under observation had been deprived of its sensation when only nine weeks old. Disgust for dog's flesh could hardly have genesis in the experience of nine weeks of puppy life in the kennel of the laboratory.

Organic and vascular reaction, though not the actual excitant of emotion, does nevertheless much strengthen it. That is part of the kernel of the old contention about the strength of emotion in the art of the artist. Hamlet's description of the actor, as really moved by his expression, may be accepted as an answer.

But, returning to the main question, we are forced back toward the likelihood that the visceral expression of emotion is *secondary* to the psychical state, or rather to the cerebral nervous action correlate with that. There is plenty of evidence of the strong nexus between emotion and muscular action. As we commonly phrase it, "emotion moves us," hence the word itself. Emotion if developed in intensity, impels toward vigorous movement. Every vigorous movement of the body, though its more obvious instrument be the skeletal musculature of the limbs and trunk, involves also the less noticeable co-operation of the viscera, especially of the circulatory and respiratory. The demand made upon the muscles that move the frame for further expenditure of power involves a heightened action of the nutrient organs which supply to the muscles their material for energy. This increased action of the viscera is therefore colligate with this activity of muscles. We should therefore expect visceral action to occur along with the muscular expression of emotion. The close tie between visceral action and states of emotion need not therefore surprise us.

That emotion is primarily a cerebral process obtains support from observations where the hemispheres of the brain have been removed. Prof. Goltz observed a dog kept many months in that condition. It on no occasion gave any evidence of joy or pleasure in commerce either with man or beast. Anger or displeasure, Goltz says, it repeatedly expressed, both by gesture and by voice. Of sexual emotion it never gave a sign. Save for expression of displeasure when too roughly handled, it was indifferent and supremely neutral to its surroundings. We are, of course, in observations whose basis is such experiment as this, hopelessly cut off from introspective help. It can be urged that the expression of emotion might be provocable, and nevertheless the psychical emotion remain absent. On such an hypothesis the same stimulus which excites the mind must excite concurrently and *per se* excite motor centres producing movement appropriate to an affective process in the mind. This is not improbable. All sensations referred to the body itself rather than interpreted as qualities of objects in the external world, tend to be tinged with "feeling." Sense organs which initiate sensations tinged with feeling tend to excite motor centres directly and imperatively. Hence, in animals reduced to merely spinal condition, stimuli calculated to produce pain normally (of course, unable to do so in a spinal animal incapable of consciousness), evoke movements appropriate for escape from or removal of the stimulus applied. Now "feeling" is implicit in the emotional state; the state is an "affective state." In the evolution of emotion the revival of "feelings" pleasurable and painful must have played a large part. Hence the close relation of emotion with sense organs that can initiate bodily pain or pleasure, and hence its connection with impulsive or instinctive movement. There is no wide interval between the reflex movement of the spinal dog, whose foot attempts to scratch away an irritant applied to its back—both leg and back absolutely detached from consciousness—and the reaction of the decerebrate dog that turns and growls and bites at the fingers holding his hind foot too roughly. In the former case the motor reaction occurs, although the mind is not even aware of the stimulus, far less percipient of it as an irritant. The action occurs, and plays the pantomime of feeling; but no feeling comes to pass. In the latter case the motor reaction occurs, and is expressive of emotion; but it is probably the reaction of an organic machine, which can be started working, though the mutilation precludes the psychosis of emotion.

And with the gesture and the attitude will occur the visceral concomitant. It would be consonant with what we know of reflex action if the spur that started the muscular expression should simultaneously and of itself initiate, also, the visceral adjunct reaction. It is almost impossible to believe that with the mere stump of brain that remained to Goltz's dog there could be any elaboration of a percept. All trace of memory was lacking to the creature. Yet though not evincing other emotion, anger it showed as far as expression can yield revelation. Fear, joy, affection seem, therefore, in the observation of this skilled observer of animal mind, to demand higher nervous organisation than does anger. Be that as it may, the retention of its expression by Goltz's dog indicates that by "retrogradation" the complex movement of expression has in certain emotions passed into a simple reflex act. When the habituating practice of acts is carried far the determining motives finally become, even in impulsive acts, weaker and more transient. The external stimulus originally aroused a strongly affective group of ideas, which operated as a motive, but now it causes a discharge of the act before it can be apprehended as an idea. The impulsive movement of a "lower," "coarser," so-called "animal" emotion, has in this case become an automatic reflex process no longer necessarily combined with the psychical state whence it arose, of which it is normally at once the adjunct and the symbol.

C. S. SHERRINGTON.

## THE CENTENARY OF THE ROYAL COLLEGE OF SURGEONS.

MR. VICTOR PLARR'S article, in last week's NATURE, on the celebration of the centenary of the Royal College of Surgeons of England contained a brief statement of the ceremonies which were to commence on the day we went to press. The proceedings were opened on Wednesday morning, July 25, when demonstrations were given in the Hunterian Museum of the College by the conservator, Prof. C. Stewart, F.R.S., who conducted visitors round the galleries, pointing out and describing some of the more important and interesting specimens. At the same time, in the theatre of the Examination Hall, Dr. T. G. Brodie, director of the laboratories of the Conjoint Board, gave an account of some of the work recently carried out in the research laboratories. In the evening a conversazione was held at the College, and was attended by many distinguished guests. Demonstrations were again given by Prof. Stewart and Dr. Brodie on Thursday morning; and in the afternoon, Sir William MacCormack, the president, delivered an address of welcome, and presented the diploma of Honorary Fellow to the Marquis of Salisbury and the Earl of Rosebery. As already stated (p. 294), the Prince of Wales received the diploma on July 24; and the form of the Royal diploma is the same as that employed for all the Honorary Fellowships.

The following is the list of other Honorary Fellows to whom diplomas were presented on Thursday:—E. Albert, professor of clinical surgery, University of Vienna; C. B. Ball, Regius professor of surgery, University of Dublin; E. Bassini, professor of clinical surgery, Royal University of Padua; E. H. Bennett, professor of surgery, Trinity College, Dublin; J. W. Berg, professor of surgery, Royal Caroline Institute of Medicine and Surgery, Stockholm; Prof. von Bergmann, Berlin; O. Bloch, professor of surgery, University of Copenhagen; E. Bottini, professor of clinical surgery, Royal University of Pavia; I. H. Cameron, professor of clinical surgery, University of Toronto; Dr. Salvador Cardenal Fernandez, vice-president, Royal Academy of Medicine and Surgery, Barcelona; Antonino D'Antona, professor of surgery, Royal University of Naples; Francesco Durante, professor of clinical surgery, Royal University of Rome; Prof. Dr. Friedrich von Esmarch, Kiel; W. S. Halsted, professor of surgery, Johns Hopkins University, Baltimore; Hon. Sir W. H. Hingston, professor of clinical surgery, University of Laval; Surgeon-General James Jameson, C.B., Director-General, Army Medical Service; W. W. Keen, professor of the principles of surgery and of clinical surgery, Jefferson Medical College, Philadelphia; Theodor Kocher, professor of surgery, University of Bern; Prof. Dr. Franz König, Berlin; Prof. Kosinskij, professor of surgery in the University of Warsaw; Prof. Dr. E. G. F. Küster, Marburg; Elie Lambotte, Brussels; Odilon Marc Lannelongue, professor of surgical pathology, Faculty of Medicine of Paris; Karl Gustaf Lennander, professor of surgery and obstetrics, University of Upsala; W. Macewen, F.R.S., Regius professor of surgery, University of Glasgow; Colonel Kenneth MacLeod, professor of clinical and military medicine, Army Medical School, Netley; Julius Nicolaysen, professor of surgery, Royal University of Christiania; Sir Henry Frederick Norbury, K.C.B., Director-General, Medical Department of the Royal Navy; Leopold Ollier, professor of clinical surgery, University of Lyons; Victor Pachoutine, president, Imperial Military Academy of Medicine, St. Petersburg; Samuel Pozzi, professor in the Faculty of Medicine of Paris; Colonel D. C. O'Connell Raye, Indian Medical Service; T. G. Roddick, professor of surgery, McGill University, Montreal; Federico Rubio y Gali, member of the Royal Academy of Medicine of Madrid; Nicolas Wassilievitch Sklifossovsky, director and Emeritus professor, Imperial Clinical Institute of the Grand Duchess Helena Pavlovna, St. Petersburg; Paul Tillaux, professor of clinical surgery, Faculty of Medicine of Paris; Nicolas Veliaminoff, professor of surgery, Imperial Military Academy of Medicine, St. Petersburg; John Collins Warren, professor of surgery, Harvard University; Robert Fulton Weir, professor of clinical surgery, Columbia University, New York. After the presentation brief addresses of thanks were delivered by Prof. v. Bergmann of Berlin, Prof. Durante of Rome, Dr. W. W. Keen of Philadelphia, Prof. Lannelongue, and Dr. T. G. Roddick of Montreal.

## FACTS OF INHERITANCE.[1]

ONE of the distinctive features of the nineteenth century has been a reduction in the number of supposed separate powers or entities—the use of William of Occam's razor, in fact. In view of this progress towards greater precision of phraseology, it cannot be a matter for surprise that a biologist should affirm that to speak of the "Principle of Heredity" in organisms is like speaking of the "Principle of Horology" in clocks. For heredity is certainly no power or force, or principle, but a convenient term for the relation of organic or genetic continuity which binds generation to generation.

Another distinctive feature in scientific progress has been the introduction of precise measurement. In the development of natural knowledge, science begins where measurement begins. This is the case in regard to inheritance. While nothing can take the place of experiment, much has been gained by the application of statistical and mathematical methods to biological results—a new contact between different disciplines—which we may particularly associate with the names of Mr. Francis Galton and Mr. Karl Pearson.

### I. THE PHYSICAL BASIS OF INHERITANCE.

What was for so long quite hidden from inquiring minds, or but dimly discerned by a few, is now one of the most marvellous of biological commonplaces—that the individual life of the great majority of plants and animals begins in the union of two minute elements—the sperm-cell and the egg-cell. If inheritance includes all that the living creature is or has to start with in virtue of its genetic relation to its parents and ancestors, then it is plain that the physical basis of inheritance is in the fertilised ovum. As regards property, there is an obvious distinction between the inheritance and the person who inherits, but there is no such distinction in biology. The fertilised egg-cell *is* the inheritance, and is at the same time the potential inheritor.

---

[1] Abridged from a discourse delivered at the Royal Institution on Friday March 30, by Prof. J. Arthur Thomson, F.R.S.

An organic inheritance means so much, even when we use the magic word potentiality, that we may consider for a moment the difficulty which rises in the minds of many when they remember that the egg-cell is often microscopic, and the sperm-cell often only 1/100,000th of the ovum's size. Can there be room, so to speak, in these minute elements for the complexity of organisation supposed to be requisite? The difficulty will be increased if the current opinion be accepted that only the nuclei within the germ-cells are the true bearers of the hereditary qualities.

In reference to this difficulty, it may be recalled that the students of physics tell us that the image of a *Great Eastern* filled with framework as intricate as that of the daintiest watches does not exaggerate the possibilities of molecular complexity in a spermatozoon, whose actual size may be less than the smallest dot on the watch's face. Secondly, as we learn from embryology that one step conditions the next and that one structure grows out of another, we are not forced to stock the microscopic germ-cells with more than initiatives. Thirdly, we must remember that the development implies an interaction between the growing organism and a complex environment without which the inheritance would remain unexpressed, and that the full-grown organism includes much that was not inherited at all, but has been acquired as the result of nurture or external influence.

The central problem of heredity is to form some conception of what we have called the relation of genetic continuity between successive generations; the central problem of inheritance is to measure the resemblances and differences in the hereditary characters of successive generations, and to arrive, if possible, at some formula which will sum up the facts. Therefore, while it is interesting to ask how an organisation supposed to be very complex may be imagined to find physical basis in a microscopic germ-cell, the same sort of question may be raised in regard to a ganglion-cell. It is not distinctively a problem of heredity. Similarly, while it is interesting to inquire into the orderly and correlated succession of events by which the fertilised egg-cell gives rise to an embryo, this is the unsolved problem of physiological embryology.

In the preformationist theories, which asserted the pre-existence of the organism and all its parts, in miniature, within the germ—there was a kernel of truth well concealed within a thick husk of error. For we may still say that the future organism is implicit in the germ, and that the germ contains not only the rudiment of the adult organism, but the potentiality of successive generations as well. But what baffled the earlier investigators was the question how the germ-cell comes to have this ready-made organisation, this marvellous potentiality.

An attempt to solve this difficulty of accounting for the complex organisation presumed to exist in the germ-cell is expressed in a theory which occurred at intervals in the long period between Democritus and Darwin, the theory of pangenesis. On this theory, the cells of the body are supposed to give off characteristic and representative gemmules; these are supposed to find their way to the reproductive elements, which thus come to contain concentrated samples of the different components of the body, and are, therefore, able to develop into an offspring like the parent. The theory involves many hypotheses, and is avowedly unverifiable in direct sense-experience, but it is more to the point to notice that there is another theory of heredity which is, on the whole, simpler, which seems, on the whole, to fit the facts better, especially the fact that our experience does not warrant the conclusion that the modifications or acquired characters of the body of the parent affect in any specific and representative way the inheritance of the offspring.

As is well known, the view which most biologists now take of the uniqueness of the germ-cells is expressed in the phrase "germinal continuity." There is a sense, as Mr. Galton says, in which the child is as old as the parent, for when the parent's body is developing from the fertilised ovum, a residue of unaltered germinal material is kept apart to form the future reproductive cells, one of which may become the starting-point of a child. In many cases, from worms to fishes, the beginning of the lineage of germ-cells is demonstrable in very early stages before the differentiation of the body-cells has more than begun. In the development of the threadworm of the horse, according to Boveri, the very first cleavage divides the fertilised ovum into two cells, one of which is the ancestor of all the body-cells, and the other the ancestor of all the germ-cells. In other cases, particularly among plants, the segregation of germ-cells is not demonstrable until a relatively late stage. Weismann, generalising from cases where it seems to be visibly demonstrable, maintains that in all cases the germinal material which starts an offspring owes its virtue to being materially continuous with the germinal material from which the parent or parents arose. But it is not on a continuous lineage of recognisable germ-*cells* that Weismann insists, for this is often unrecognisable, but on the continuity of the germ-*plasm*—that is, of a specific substance of definite chemical and molecular structure which is the bearer of the hereditary qualities. In development, a part of the germ-plasm, "contained in the parent egg-cell is not used up in the construction of the body of the offspring, but is reserved unchanged for the formation of the germ-cells of the following generation." Thus the parent is rather the trustee of the germ-plasm than the producer of the child. In a new sense, the child is a chip of the old block. The conception of a germ-plasm is hypothetical, just as the conception of a specific living stuff or protoplasm is hypothetical. In the complex microcosm of the cell, we cannot point to any one stuff and say, "this is protoplasm"; it may well be that vital activity depends upon several complex stuffs which, like the members of a carefully constituted firm, are characteristically powerful only in their inter-relations. In the same way, we cannot demonstrate the germ-plasm, even if we may assume that it has its physical basis in the stainable nuclear bodies or chromosomes. The theory has to be judged, like all conceptual formulæ, by its adequacy in fitting facts.

### II. DUAL NATURE OF INHERITANCE.

Apart from exceptional cases, the inheritance of a multicellular animal or plant is dual, part of it comes from the mother and part of it from the father.

Prof. E. B. Wilson states the general opinion of experts somewhat as follows:—As the ovum is much the larger, it is believed to furnish the initial capital—including it may be a legacy of food-yolk—for the early development of the embryo. From both parents alike comes the inherited organisation which has its seat (according to many) in the readily stainable (chromatin) rods of the nuclei. From the father comes a little body (the centrosome) which organises the machinery of division by which the egg splits up, and distributes the dual inheritance equally between the daughter-cells.

Recent researches confirm a prophecy which Huxley made in 1878: "It is conceivable, and indeed probable, that every part of the adult contains molecules derived both from the male and from the female parent; and that, regarded as a mass of molecules, the entire organism may be compared to a web of which the warp is derived from the female and the woof from the male." "What has since been gained," Prof. Wilson says, "is the knowledge that this web is to be sought in the chromatic substance of the nuclei, and that the centrosome is the weaver at the loom."

In regard to these conclusions, three notes are necessary. (*a*) Although inheritance is dual, it is in quite as real a sense multiple, from ancestors through parents. (*b*) If Loeb is able to induce artificial parthenogenesis in sea-urchins' eggs exposed for a couple of hours to sea-water to which some magnesium chloride has been added; if Delage is able to fertilise and to rear normal larvæ from non-nucleated ovum-fragments of sea-urchin, worm and mollusc, we should be chary of committing ourselves definitely to the conclusion that the nuclei are the exclusive bearers of the hereditary qualities, or that both must be present in all cases. Furthermore, the fact that an ovum without any sperm-nucleus, or an ovum-fragment without any but a sperm-nucleus, can develop into a normal larva points to the conclusion, probable also on other grounds, that each germ-cell, whether ovum or spermatozoon, bears a complete equipment of hereditary qualities. (*c*) It must be carefully observed that our second fact does not imply that the dual nature of inheritance must be patent in the full-grown offspring, for hereditary resemblance is often strangely unilateral, the characters of one parent being "prepotent," as we say, over those of another.

### III. DIFFERENT DEGREES OF HEREDITARY RESEMBLANCE.

One step of progress during the Darwinian era has been the recognition of inheritance as a fact of life which requires no further proof.

Yet this aspect of the study of heredity is by no means worked out. Thus there are some characters, *e.g.* tendency to certain diseased conditions, which are more frequently transmitted than others, and we ought to have, in each case, precise statistics as to the probabilities of transmission.

Again, there are some subtle qualities whose heritability must not be assumed without evidence. Thus it is of very great importance to students of organic evolution that Prof. Karl Pearson has recently supplied, for certain cases, definite proof of the inheritance of fecundity, fertility and longevity.

The familiar saying, "like begets like," should rather read, "like tends to beget like," since variation is quite as important a fact as complete hereditary resemblance. If it seems that in many cases the offspring is practically a facsimile reproduction of the parent, this may be due to absence of variation, or, what comes almost to the same thing, to great completeness of inheritance; but it is more likely to be due to our ignorance, to our inability to detect the idiosyncrasies.

But it will be granted that the completeness with which the characters of race, genus, species and stock are reproduced generation after generation is one of the large facts of inheritance. But this does not sum up our experience, and we must face the task of considering the different degrees of hereditary resemblance. For these a confused classification and a troublesome terminology has been suggested, but it will be enough to restrict attention to three familiar cases—blended, exclusive and particulate inheritance.

A preliminary consideration must be attended to. It is a matter of observation that there are great differences in the degree in which offspring resemble their parents; but it is surely a matter of conjecture that lack of resemblance is necessarily due to incompleteness in the inheritance. Indeed, the fact that the resemblance so often reappears in the third generation makes it probable that the incompleteness is not in the inheritance, but simply in its expression. The characters which seem to be absent, to "skip a generation," as we say, are probably part of the inheritance, as usual. But they remain latent, neutralised, silenced (we can only use metaphors) by other characters, or else unexpressed because of the absence of the appropriate stimulus.

(*a*) In *blended* inheritance, the characters of the two parents, *e.g.* in regard to a particular structure, such as the colour of the hair, may be intimately combined in the offspring. This is particularly well seen in some hybrids, where the offspring often seems like the mean of the two parents; it is probably the most frequent mode of inheritance.

(*b*) In *exclusive* inheritance, the expression of maternal or of paternal characters in relation to a given structure, such as eye-colour, is suppressed. Sometimes the unilateral resemblance is very pronounced, and we say that the boy is "the very image of his father," or the daughter "her mother over again"; though even more frequently the resemblance seems "crossed," the son taking after the mother, and the daughter after the father.

(*c*) It is convenient to have a third category for cases where there is neither blending nor exclusiveness, but where in the expression of a given character, part is wholly paternal and part wholly maternal. This is called *particulate* inheritance. Thus, an English sheep-dog may have a paternal eye on one side, and a maternal eye on the other. Suppose the parents of a foal to be markedly light and dark in colour; if the foal is light brown the inheritance in that respect is blended, if light or dark it is exclusive, if piebald it is particulate. In the last case there is in the same character an exclusive inheritance from both parents.

The facts above referred to may be considered in another aspect, in terms of what is called the quality of prepotency. In the development of a character the paternal or the maternal qualities may predominate, as in unequal blending where there is relative prepotency, or in exclusive inheritance where the prepotency in respect to a given character is absolute. It seems doubtful whether we gain much by using the word, since all these general terms are apt to form the dust particles of intellectual fog; but we have to do with the fact that in respect to certain characters the paternal inheritance seems more potent than the maternal, or *vice versa*.

It seems that one of the ways in which the quality of prepotency may be developed is by inbreeding, as Prof. Ewart and others have maintained.

Therefore, as inbreeding may be frequent in nature, especially in gregarious and isolated groups, and as it tends to develop prepotency, we are able to understand better how new variations may have been fixed in the course of evolution. And we can appreciate the position maintained by Reibmayr, that the evolution of a human race implies alternating periods of dominant inbreeding, and dominant cross-breeding. The inbreeding gives fixity to character, the cross-breeding averts degeneracy and stimulates new variations which form the raw material of progress.

Until we have more precise statistical data in regard to blended, exclusive and particulate inheritance, we cannot hope to simplify the matter with any security. But perhaps a unified view will be found in the theoretical conception of a germinal struggle in the arcana of the fertilised ovum, a struggle in which the maternal and paternal contributions may blend and harmonise, or may neutralise one another, or in which one may conquer the other, or in which both may persist without combining. We have extended the wide conception of the struggle for existence in many directions; it may be between organisms akin or not akin, between plants and animals, between organisms and their inanimate environment, between the sexes, between the different parts of the body, between the ova, between the spermatozoa, between the ova and the spermatozoa, and Weismann has suggested that it may also be between the constituents of the germ-plasm.

## IV. REGRESSION.

We have already referred to the fact that there is a sensible stability of type from generation to generation. "The large," Mr. Galton says, "do not always beget the large, nor the small the small; but yet the observed proportion between the large and the small, in each degree of size and in every quality, hardly varies from one generation to another." In other words, there is a tendency to keep up a specific average. This may be partly due to the action of natural elimination, weeding out abnormalities, often before they are born. But it is to be primarily accounted for by what Mr. Galton calls the fact of "filial regression."

As Mr. Galton puts it, society moves as a vast fraternity. The sustaining of the specific average is certainly not due to each individual leaving his like behind him, for we all know that this is not the case. It is due to a regression which tends to bring the offspring of extraordinary parents nearer the average of the stock. In other words, children tend to differ less from mediocrity than their parents.

This big average fact is to be accounted in terms of that genetic continuity which makes an inheritance not dual, but multiple. "A man," says Mr. Pearson, "is not only the product of his father, but of all his past ancestry, and unless very careful selection has taken place, the mean of that ancestry is probably not far from that of the general population. In the tenth generation a man has [theoretically] 1024 tenth great-grandparents. He is eventually the product of a population of this size, and their mean can hardly differ from that of the general population."

At this point one should discuss reversion or atavism, but it is exceedingly difficult to get a firm basis of fact. The term reversion includes cases where *through inheritance* there reappears in an individual some character which was not expressed in his parents, but which did occur in an ancestor. The character whose reappearance is called a reversion may be found within the verifiable family, within the breed, within the species, or even in a presumed ancestral species.[1]

The best illustrations of reversion are furnished by hybrids. Thus in one of Prof. Cossar Ewart's experiments a pure white fantail cock pigeon, of old-established breed, which in colour had proved itself prepotent over a blue pouter, was mated with a cross previously made between an owl and an archangel, which was far more of an owl than an archangel. The result was a couple of fantail-owl-archangel crosses, one resembling the Shetland rock-pigeon, and the other the blue rock of India.

But great carefulness is necessary in arguing from the results of hybridisation to those of ordinary mating, and even if some of the phenomena of exclusive inheritance seem to show reversion to a near ancestor we need a broader basis of fact than we have at present before we can formulate any law. The recorded cases show that many phenomena are labelled reversions on the flimsiest evidence. Thus the occurrence of a Cyclopean human monster with a median eye has been called a reversion to the sea-squirt, and gout has been called a reversion to the reptilian condition of liver and kidneys. Often there is not the slightest attempt to discriminate between true reversion (*i.e.* the re-expression of latent ancestral characters) and the phenomena of arrested development, or of abnormalities which have been induced from without. Often, too, there has been no scruple in naming or inventing the ancestor to whom the reversion is supposed to occur, although evidence of the pedigree is awanting; and the vicious circle is not unknown of arguing to the supposed ancestor from the supposed reversion, and then justifying the term reversion from its resemblance to the supposed ancestor. Little allowance has been made for coincidence, and the postulate of characters remaining latent for millions of years is made as glibly as if it were just as conceivable as a throw-back to a great-grandfather.

---

[1] Prof. Karl Pearson defines a *reversion* as "the full reappearance in an individual of a character which is recorded to have occurred in a *definite* ancestor of the same race," and *atavism* as "a return of an individual to a character not typical of the race at all, but found in allied races supposed to be related to the evolutionary ancestry of the given race." "In reversion we are considering a variation, normal or abnormal, from the standpoint of *heredity in the individual*; in atavism we are considering an abnormal variation from the standpoint of the *ancestry of the race*." But the two words seem to be used by some authors in the converse way, or as equivalent, and it is surely difficult to define the field of abnormal variation.

There seems no way out of the theory that characters may lie latent for a generation or for generations, or in other words that certain potentialities or initiatives which form part of the heritage may remain unexpressed for lack of the appropriate liberating stimulus, or for other reasons, or may have their normal expression disguised. But it does not follow that the reappearance of an ancestral character not seen in the parents is necessarily due to the reassertion of latent elements in the inheritance. It may be a case of ordinary regression; it may be a case of arrested development; it may be an extreme variation whose resemblance to an ancestral characteristic is a coincidence; it may be an individually acquired modification, reproduced apart from inheritance, by a recurrence of suitable external conditions, and so on. What are called reversions are probably in many cases misinterpretations.

### V. GALTON'S LAW.

The most important general conclusion which has yet been reached in regard to inheritance is formulated in Galton's Law. Mr. Galton was led to it by his studies on the inheritance of human qualities, and more particularly by a series of studies on Basset hounds. It is one of those general conclusions which have been reached statistically, and I must refer for the evidence and also for its strictest formulation to the revised edition of Mr. Pearson's "Grammar of Science."[1]

As we have seen, it is useful to speak of a heritage as dual, half derived from the father and half from the mother. But the heritable material handed on from each parent was also dual, being derived from the grandparents. And so on, backwards. We thus reach the idea that a heritage is not merely dual, but in a deeper sense multiple.

To appreciate the possible complexity of our mosaic inheritance we must recall the number of our ancestors. We have two parents, four grandparents, eight great-grandparents, about sixteen great-great-grandparents, and so on. But as we go backwards the theoretical number far exceeds the reality; a reduction in the number of ancestors is brought about by inter-marriage, as this table (from Lorenz) in reference to Kaiser Wilhelm II. clearly shows.

| *Generations.* | I. | II. | III. | IV. | V. | VI. | VII. | VIII. | IX. | X. | XI. | XII. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| (1) Theoretical Number. | 2 | 4 | 8 | 16 | 32 | 64 | 128 | 256 | 512 | 1024 | 2048 | 4096 |
| (2) Actual number known. | 2 | 4 | 8 | 14 | 24 | 44 | 74 | 111 | 162 | 206 | 225 | 275 |
| (3) Inadequately known. | | | | | | | | 5 | 15 | 50 | 117 | 258 |
| (4) Probable total. | | | | | | | | 116 | 177 | 256 | 342 | 533 |

According to Galton's Law, "the two parents between them contribute *on the average* one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth; and so on, the sum of the series, $\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+$&c., being equal to 1, as it should be. It is a property of this infinite series that each term is equal to the sum of all those that follow: thus $\frac{1}{2}=\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+$&c.; $\frac{1}{4}=\frac{1}{8}+\frac{1}{16}+$&c., and so on. The prepotencies or subpotencies of particular ancestors, in any given pedigree, are eliminated by a law that deals only with *average* contributions, and the varying prepotencies of sex in respect to different qualities are also presumably eliminated."

The aim of this lecture has been to present in brief compass a statement of the leading facts of inheritance, which should be clear in the minds of all. Nothing has been said in regard to the transmissibility of acquired characters, for this cannot be ranked at present as an established fact, and some other doubtful points have been left unmentioned. The study of inheritance leaves a fatalistic—almost paralysing—impression on many minds, especially perhaps if it be believed that the acquired results of experience and education—of "nurture," in short, cannot be entailed upon the offspring. To some extent this fatalistic impression is justified, but it is well that it should rest upon a sound basis of fact and not on exaggerations. In a sense we can never get away from our inheritance. As Heine said half bitterly, half laughingly, "A man should be very careful in the selection of his parents." On the other hand, although the human organism changes slowly in its heritable organisation, it is very modifiable individually, and "nature" can be bettered by "nurture." If there is little scientific warrant for our being other than sceptical at present as to the inheritance of acquired characters, this scepticism lends greater importance than ever, on the one hand, to a good "nature," to secure which for offspring is part of the problem of careful mating; and, on the other hand, to a good "nurture," to secure which for our children and children's children is one of the most obvious of duties, the hopefulness of the task resting upon the fact that, unlike the beasts that perish, man has a lasting external heritage, capable of endless modification for the better.

---

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. A. RENDLE SHORT, of University College, Bristol, has been awarded the gold medal and exhibition in physiology, the gold medal and exhibition in materia medica, and first-class honours in anatomy, upon the results of the recent Intermediate M.B. examination of the University of London. The exhibitions in physiology and materia medica are of the value of 80*l.* and 60*l.*

A DISCUSSION on the teaching of geography will be held at Cambridge on Friday, August 24, under the auspices of the Geographical Association, and in connection with the Summer Meeting. Prof. W. M. Davis, of Harvard University, will occupy the chair, and among the subjects to be brought before the Association are class excursions, map drawing, the use of the globe, geography in the grammar school, and possibilities and limitations of geography in a day school. There are several exhibits of interest to teachers of geography in the education exhibition, arranged in connection with the Summer Meeting.

LORD BUTE has offered the University of St. Andrews a sum of 20,000*l.*, to be held as a fund for endowing a chair of anatomy, upon the following conditions:—(1) That the said sum of 20,000*l.* shall be paid to the University not later than ten years hence. The exact date cannot be specified, as it will depend upon completion of certain works at Cardiff. Interest at 3 per cent. will be payable to the University from the time of the appointment of the first professor until they receive the principal sum; (2) that the first presentation to the chair shall be in favour of Mr. Musgrove, the present holder of the lectureship in anatomy in St. Andrews; (3) that the lectures shall be given exclusively in St. Andrews; (4) that the course shall meet the requirements of the two first *Anni Medici*; and (5) that before the beginning of the University session, 1901–1902, the approval of the Universities Committee of the Privy Council to the establishment of the chair under the foregoing conditions be obtained, and that the approval of Lord Bute or his representatives be obtained to any further conditions embodied in the ordinance instituting the chair.

THE relations between scientific work and industrial progress have been so often described in these columns that there is little new to be said upon the subject. But though readers of NATURE may be familiar with many instances of the close connection between science and industry, it will be a long time before the knowledge filters down to the general public and starts a reaction in commercial and manufacturing circles. Every man of science who takes advantage of an opportunity to impress the value of scientific observation and research upon the minds of citizens, is thus doing a service to the nation, as well as extending interest in natural knowledge. Dr. P. Bedson, professor of chemistry at the Durham College of Science, has, we are glad to see, recently shown the Economic Society of Newcastle-on-Tyne some of the lessons taught by the growth of science and industry in Germany during the present century. A reasonable and organised system of education, and schools in which students receive a thorough grounding in the principles of science, and afterwards contribute something to the advancement of knowledge, are the chief factors in Germany's industrial progress. Referring to the system of examinations which still dominates so much of our educational work, and finds its highest development in connection with university teaching, Prof. Bedson points out that it partakes of the character of the training of a stud of racers. He adds:—"Possibly the instinct of sport, so characteristic of the English people, it is which commends the system of competitive examination. Too much is made of what should be regarded as a minor duty of the University, viz. the testing and marking of its students, and too little of the higher function, the training of students under first-rate teaching, with the object that those so trained should help forward the advancement of knowledge." It is satisfactory to know that the movement in favour of rational teaching in elementary schools, and regard for research in institutions of university rank, is gradually affecting scientific education in this country.

---

[1] Reference should, however, be made to Mr. Pearson's recent paper *Proc. Roy. Soc.*, lxvi. 1900, pp. 140–164) on the law of reversion.

---

## SCIENTIFIC SERIALS.

*Symons's Monthly Meteorological Magazine*, July.—This number contains the completion of two interesting papers, by Mr. E. D. Archibald, on Indian famine-causing droughts, and their prevision. The principal facts are summarised as follows: (1) Extensive droughts occur in the dry area of Southern India at intervals of nine to twelve years, and usually, but not regularly, about a year before the sun-spot minimum. When the conditions are sufficiently acute, famine occurs in the following year. (2) A severe drought in the peninsular of Southern India is followed by a severe drought and ensuing famine in Northern India in about five cases out of seven. (3) Summer droughts tend to occur in Northern India in years of maximum sun-spot, connected in some way with the abnormal high pressure over Western Asia which prevails at such epochs. There is thus a double periodicity of droughts and famine in North India, and a single periodicity in South India in the sun-spot cycle, though the relation between the phenomena is too spasmodic and irregular to be utilised as a trustworthy factor for prevision.

*Annalen der Physik*, No. 6.—Interruption spark in the alternating circuit with metallic electrodes, by L. Kallir. The author shows that the impossibility of producing an alternate-current arc between metallic electrodes is due to the fact that the spark is confined to one semi-period of the current. Or if it extends over several periods, it is intermittent, and only appears at every alternate semi-period.—Thermoelectric force of some metallic oxides and sulphides, by A. Abt. Pyrolusite, pyrrhotite, pyrites, and chalcopyrite were used in conjunction with various metals or with each other. A pyrites-chalcopyrite couple gave an E.M.F. 10·8 times as high as an antimony-bismuth couple under the same conditions.—Anomalous electromagnetic rotatory dispersion, by A. Schmauss. Measurements of the Faraday effect for various wave-lengths in fuchsine solutions and in didymium glass justify the general conclusion that optical anomaly in dispersion is invariably associated with a corresponding electromagnetic anomaly. In strongly absorbing media the anomaly extends for a considerable distance on both sides of the absorption band, and it increases with the concentration and with the narrowness and sharpness of the absorption band.—Point discharges, by E. Warburg. In carefully purified nitrogen, the current intensity obtained from the discharge of a fine point charged to $-3310$ volts is 200 times as great as from a point charged to $+5180$ volts. A slight admixture of oxygen reduces the proportion to $4:1$.—Band spectrum of aluminium, by G. A. Hemsalech. The author quotes some experiments which go to show that the band spectrum of aluminium is due, not to the oxide, but to the metal itself.—Behaviour of radium at low temperatures, by O. Behrendsen. Cooling a radium preparation down to the temperature of liquid air reduces its activity by 50 per cent. Restoration to the ordinary temperature produces a considerable but transient increase of activity.—Production of kathode rays by ultra-violet light, by P. Lenard. The discharge of electrified bodies by ultra-violet light is due to their emitting kathode rays when the ultra-violet light impinges upon them. The author exhausted a vacuum tube until it no longer allowed any discharge to pass. He then exposed the kathode to ultra-violet rays from a zinc spark gap. The discharge set in again immediately, but no discharge could be obtained by similarly illuminating the anode. The rays which produce the discharge across the absolute vacuum can be deflected by a magnet, and their velocity is about one-thirtieth of the velocity of light.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, February 8.—"On Electric Touch and the Molecular Changes produced in Matter by Electric Waves." By Jagadis Chunder Bose, M.A., D.Sc., Professor of Physical Science, Presidency College, Calcutta. Communicated by Lord Rayleigh, F.R.S.

It is claimed that the experiments described in the paper show:—

(1) That ether waves produce molecular changes in matter.

(2) That the molecular or allotropic changes are attended with changes of electric conductivity, and this explains the action of the so-called coherers.

(3) That there are two classes of substances, positive and negative, which exhibit opposite variations of conductivity under the action of radiation.

(4) That the production of a particular allotropic modification depends on the intensity and duration of incident electric radiation.

(5) That the continuous action of radiation produces oscillatory changes in the molecular structure.

(6) That these periodic changes are evidenced by the corresponding electric reversals.

(7) That the "fatigue" is due to the presence of the "radiation product," or strained B variety.

(8) That by means of mechanical disturbance or heat, the strained product can be transformed into the normal form, and the sensitiveness may thereby be restored.

June 21.—"An Experimental Investigation into the Flow of Marble." By Frank D. Adams, M.Sc., Ph.D., Professor of Geology in McGill University, Montreal, and John T. Nicolson, D.Sc., M.Inst.C.E., Head of the Engineering Department, Municipal Technical School, Manchester. Communicated by Prof. H. L. Callendar, F.R.S.

The following is a summary of the results arrived at:—

(1) By submitting limestone or marble to differential pressures exceeding the elastic limit of the rock and under the conditions described in this paper, permanent deformation can be produced.

(2) This deformation, when carried out at ordinary temperatures, is due in part to a cataclastic structure and in part to twinning and gliding movements in the individual crystals comprising the rock.

(3) Both of these structures are seen in contorted limestones and marbles in nature.

(4) When the deformation is carried out at 300° C., or better at 400° C., the cataclastic structure is not developed, and the whole movement is due to changes in the shape of the component calcite crystals by twinning and gliding.

(5) This latter movement is identical with that produced in metals by squeezing or hammering, a movement which in metals, as a general rule, as in marble, is facilitated by increase of temperature.

(6) There is therefore a flow of marble just as there is a flow of metals, under suitable conditions of pressure.

(7) The movement is also identical with that seen in glacial ice, although in the latter case the movement may not be entirely of this character.

(8) In these experiments the presence of water was not observed to exert any influence.

(9) It is believed, from the results of other experiments now being carried out but not yet completed, that similar movements can, to a certain extent at least, be induced in granite and other harder crystalline rocks.

"On the Effects of Changes of Temperature on the Elasticities and Internal Viscosity of Metal Wires." By Andrew Gray, LL.D., F.R.S., Professor of Natural Philosophy in the University of Glasgow, and Vincent J. Blyth, M.A., and

James S. Dunlop, M.A., B.Sc., Houldsworth Research Students in the University of Glasgow.

"The Distribution of Molecular Energy." By J. H. Jeans, B.A. Communicated by Prof. J. J. Thomson, F.R.S.

### PARIS.

**Academy of Sciences,** July 23.—M. Maurice Lévy in the chair.—Notice on Charles Friedel, by M. Georges Lemoine.—Visual observations of the corona of May 28, made by Mr. W. H. Wesley at Algiers, with the Coudé equatorial of 0·318 metre aperture, by M. Lœwy.—Phosphoric acid in the presence of saturated solutions of calcium bicarbonate, by M. Th. Schlœsing. Solutions of phosphoric acid were added to saturated solutions of calcium bicarbonate, and carbon dioxide withdrawn by a slow current of air. From the analyses of the precipitated salt, interesting conclusions are drawn as to the use of superphosphates as manure.—Report upon the proposed revision of the arc of the meridian at Quito, by M. Poincaré. The Commission report that it is of opinion that the proposed revision of the arc of meridian at Quito should be carried out. The arc measured should be 6° instead of 4° 5′, the work being done by the staff of the Geographical Service of the Army under the control of the Academy of Sciences.—On the limited problem of three bodies, by M. Lévi-Civita.—On the position and actual appearance of a new star, transformed into a nebula, by M. G. Bigourdan. The nebular constitution ascribed by Prof. Pickering to this new star, discovered by Mrs. Fleming, must have been derived from spectroscopic examination, since at the present time the object appears clearly as a star, without any trace of nebulosity.—Total eclipse of the sun of May 28. Note on the observations made at the Observatory of Algiers, by W. H. Wesley. A description of the study of the lower coronal regions.—Observations of the total eclipse of the sun of May 28, made in Spain, at Hellin, Albacete, and at Las Minas, by M. G. Bigourdan.—Observation of the solar eclipse of May 28, made at Albacete, in Spain, by M. J. Eysséric.—Observation of the total eclipse of the sun of May 28, at Las Minas, in Spain, by M. Salet.—On a system of differential equations equivalent to the problem of $n$ bodies, but admitting of one more integral, by M. W. Ebert.—On the elastic flying machine, by M. L. Lecornu.—On the electrocapillary functions of aqueous solutions, by M. Gouy.—The spectrum of radium, by M. Eug. Demarçay. Mme. Curie has succeeded in obtaining a specimen of radium chloride in which the barium is so far reduced that only a feeble spectrum of three principal rays is obtained. The radium lines, although much stronger than in the specimens previously studied, show no new ray that can be attributed to radium. In its general character the spectrum of radium approximates to those of the metals of the alkaline earths.—Solubility of a mixture of salts having a common ion, by M. Charles Touren.—On a new complex acid and its salts, palladio-oxalic acid and palladio-oxalates, by M. H. Loiseleur. Four new substances are described, palladio-oxalic acid and its silver, sodium, and barium salts. The acid is the first complex acid containing palladium that has been isolated.—On some osmyloxalates, by M. Wintrebert.—Action of some finely divided metals, platinum, cobalt and iron, upon acetylene and ethylene, by MM. Paul Sabatier and J. B. Senderens. Platinum black has no action upon pure acetylene at ordinary temperatures, but at 150° ethylene and hydrogen, together with small quantities of benzene and ethane, are produced. With cobalt, the reaction commences at 200°, ethane and hydrogen being the principal products. Iron behaves similarly to cobalt. With ethylene, platinum and copper produce practically no effect; cobalt gives ethane, hydrogen and methane, and similarly with iron.—Synthesis of paramethoxyhydratropic acid, by M. J. Bougault. The author concludes that in identifying phloretic acid with the synthetical paraoxyhydratropic acid, M. Trinius was in error.—Influence of hydrobromic acid upon the velocity of the reaction of bromine upon trimethylene, by M. G. Gustavson.—The organic solutions of ferric chloride, by M. Œchsner de Coninck. The iron salt is removed from solutions in methyl and ethyl alcohols, acetic ether and acetone by repeated filtration through animal charcoal.—On the nature of the reserve carbohydrates of the St. Ignatius bean and nux vomica, by MM. Ém. Bourquelot and J. Laurent. The albumen of these seeds appears to contain several mannane and galactanes of different molecular weights.—On the genera Palythoa and Epizoanthus, by M. Louis Roule.—A teratological process, by M. Étienne Rabaud.—The nepheline rocks of the Puy de Saint-Sandoux, by M. A. Lacroix.—The sub-Pyreneal erosions, by M. L. A. Fabre.—On the existence of carboniferous strata in the region of Igli, by M. Ficheur.—On the agglutination of blood corpuscles by chemical agents, and on the conditions of medium which favour or prevent it, by M. E. Hédon.—On the influence of phosphates and of some other mineral substances upon the proteolytic diastase of malt, by MM. A. Fernbach and L. Hubert.—The bacteriolysis of anthrax, by M. G. Malfitano.—On the function of the nucleus in the formation of hæmoglobin and in cellular protection, by M. Henri Stassano.—On the collection of potable water and protection of springs, by M. Léon Janet.

### CAPE TOWN.

**South African Philosophical Society,** June 27.—L. Péringuey, President, in the chair.—Mr. E. H. L Schwarz exhibited copies of some Bushman drawings which he had found near Nieuwoudtsville. Along with the usual reproductions of men and animals, there are certain puzzling figures which have not been recorded from other localities. One of these consists of a rude slipper-like form with seven bars across it; another is a circle with seven peripheral radiating bars, and a third shows three concentric circles, from the outer of which there extend twenty-one bars. Mr. Schwarz thought that the first-mentioned figure might be a tally.—Dr. Corstorphine gave a short note on an old beach deposit on the site of the South African Brewery at Woodstock, which had been brought to his notice by Mr. A. W. Ackermann, architect, Cape Town. Some of the sections show a layer of shells and water-worn boulders some three feet thick resting on the slate and covered by about three feet of sand and soil, but within thirty yards the deposit entirely thins out. The shells all belong to species found on the present beach.—A copy of a report on a submarine disturbance, from the magistrate at Walfish Bay, forwarded by Major Stanford, was read by the secretary. The magistrate stated that on May 31 or June 1 last, a new island appeared about 100 yards N.E. of Pelican Point. The island was about 150 feet long by 30 feet wide, and stood 12 feet above high water. It was composed of a tenacious clay; soundings gave 7–10 fathoms around it; steam was observed rising from the clay, and an intense smell of sulphuretted hydrogen was perceptible, even at a distance of five miles.—Mr. Sclater gave an account of some inscribed stones found in Cape Town.

THURSDAY, AUGUST 9, 1900.

## PRACTICAL NAVIGATION.

*Self-instruction in the Practice and Theory of Navigation.* By the Earl of Dunraven, Extra Master. Two volumes. Pp. xxv + 354 + 388. (London: Macmillan and Co., Ltd., 1900.)

THE science of navigation, apart from the practical art of seamanship, stands on a very curious footing. Based mainly on mathematical results, it presents probably the only, certainly the most conspicuous, instance of the adaptation of pure science to practical ends. As a consequence nautical astronomy, or those portions of it which are indispensable to navigation, has been systematised to such a pitch of perfection that a mechanical system has been substituted for a reasoning process. Many regard this result with satisfaction as a triumph of scientific simplicity, and pride themselves on the production of navigators capable of producing a definite practical result with the least possible expenditure in training. Perhaps it would be unjust to say that this view is shared by the Earl of Dunraven, the author of the latest book on the theory and practice of navigation. But he is not prepared to throw his known experience as a sailor and his great popularity as a successful yachtsman on the side of those who would make the Board of Trade Regulations more stringent, and would demand from applicants for the various certificates some proof that they have acquired more than a rule-of-thumb acquaintance with the various methods and formulæ that they will have to put into practice. The effect, if not the object, of his book is to show with how little knowledge one may pass the Board of Trade Examinations, and be legally entitled to assume positions of enormous responsibility. But admitting that it is desirable to give the practical seaman every chance in the examination room, and that the accurate solution of a problem is the only point to be regarded, is it easier to teach once for all the ordinary methods for the solution of a spherical triangle, or to burden the memory with a variety of rules which are available only for the solution of the particular family of problems to which these rules have been adapted? Take, for example, the case of the determination of an hour angle from the observation of an altitude in a known latitude. The candidate for a certificate, taught on the lines that Earl Dunraven approves and encourages, has to remember first of all a series of rules about declination and latitude being of the same or different names; then he has to write certain quantities down in a particular order, perform sundry acts of legerdemain, take out four different logarithmic functions of angles, add them up, and is landed in a quantity which his lordship calls "the log. of the hour angle." It is the log. sine squared of half the hour angle, but this is a detail, and if one happens to possess the particular table in which some obliging genius has given this quantity, with argument hour angle, the work is done and it may be, so far as the result is concerned, satisfactorily. To trust to the memory rather than the rigorous process of demonstration is a plan Earl Dunraven thinks admirably adapted to meet the difficulties introduced by "a wet, slippery, and tumbling deck" and the inconveniences "of a dimly-lit cabin, full of confusion and noise." We fail to perceive the particular advantages of this system, but would express any doubts on this point very modestly, for the author speaks from an actual experience, which we can very inadequately apprehend.

But if our methods of teaching are as far asunder as the poles, it is impossible to escape the influence of the cheerful, breezy style in which the book is written—a model for those who attempt to substitute teaching by written description for oral explanation. The author appears to be sitting at the same table with the student, giving him of his best, and actually pushing him through the examination. If any one has failed to satisfy the examiner that he is competent to do "a day's work," let him take Earl Dunraven for his guide, and he will become fully persuaded of the easiness of the problem, rather than of its difficulty, and will pass the ordeal with success.

The author supposes his pupil to be conversant with the multiplication table, but with practically nothing else, so he gives first a chapter on arithmetic, followed by one on the application of logarithms; the theory is dismissed in a page, and of this short summary the student is told "don't bother to read it unless you have a mind to." This is the keynote of the whole book, only those problems which can have an immediate practical significance, or can be broached in the examination room, are pressed on the student's notice. But to make amends for the lack of theory, on the practical side, the detail is very full and complete. From logarithms we pass to the description of the instruments used at sea, and so arrive at the "sailings" and that troublesome problem of the "day's work," which proves such a stumbling block for so many aspirants for certificates. At this point the author thinks it time to introduce a little algebra and trigonometry, though he advises only extra masters to read it, and we must admit that it contains some hard things, and that we should have some difficulty in solving some of the simple equations proposed by following the rules laid down for our guidance. The author is not seen at his best in these chapters, which are better taught in the schoolroom than on the ship's deck. Tides and charts, so far as their investigation and construction are needed for the examination room, are fully explained. The first volume concludes with the solution of simple problems connected with the determination of latitude, longitude, and azimuth.

We cannot get very far into the second volume without some knowledge of spherical trigonometry, and here, again, we do not find the chapters devoted to this subject altogether satisfactory. Spherical trigonometry covers a very small but well recognised subject of inquiry, and can without much difficulty be made complete. The methods are simple and easily applied, except in one point, and that is the determination of the quadrant in which the various arcs fall. Earl Dunraven has not much assistance to offer on this vexed point. He pins his faith to Haversines, and as a rule keeps free from the employment of auxiliary angles. In this he is no doubt well advised, for the advantages of the method so long insisted upon in elementary treatises are by no means so apparent in actual work. Through the intricacies of the ingenious method known as Sumner Lines, Earl Dunraven conducts us with care, especially dwelling on the use of the various tables that have been introduced to facilitate the process and hasten the result. After one or two further applications of spherical trigonometry, we are brought face to face with that curious survival, known as a Lunar Distance, and we are quite sure that the author did some violence to his sense of practical utility when he devoted so many wearisome pages to the consideration of this obsolete problem. In the examination room of the Board of Trade, the thorny difficulties of "clearing the distance" may exercise a wholesome effect on the extra master, whose fate it is to attack this problem, and induce him to acquire a greater knowledge of nautical astronomy than he would otherwise do; but we imagine in the great majority of cases the applicant endeavours to forget all about the intricacies of the problem as soon as he is possessed of his qualifying "ticket." The skill of the mechanician has done much to remove the necessity of the ingenious device, but the rapid transit of vessels from port to port, and the numerous time signals in known longitudes, give to the mariner Greenwich Time more accurately than it was ever determined by the method of lunar distances. But for some reason known only to the authorities, an acquaintance with the method is demanded, though the necessary facility in manipulating the sextant cannot so well be required. The whole process affords an interesting case of the resources of analysis outrunning in accuracy the observations to which it is applied.

"Problems," says Earl Dunraven, "will be given you in the examination room on the infernal subject of magnetism and deviation," so he has much to say about the coefficients A to E. To many, we are afraid these coefficients will remain a matter of intricate manipulation, carrying no definite meaning; but if they follow the author's guidance, they ought to issue triumphantly from the examination ordeal. His rules are admirably arranged, and, from a purely mechanical point of view, leave nothing to be desired. We could have wished that the theory had been a little fuller, but we remember, a little regretfully, that the author's object is not to teach magnetism, but to pass the reader or student through an examination of a strictly limited character. We cannot but think that the book is eminently calculated to effect this object. Admirably printed, well and lavishly illustrated, furnished with numerous examples and written in a free and easy, but lucid style, we should imagine that this work is destined to become the most popular book on the subject, and that it will be the one guide and text-book to which the young officer will apply, to help him to meet and defy the terrors of Her Majesty's examiners. W. E. P.

---

## *THE CULTIVATION AND PRODUCTION OF COFFEE.*

*Le Café, Culture—manipulation—production.* Par Henri Lecomte, Agrégé de l'Université, Docteur es Sciences, &c. Pp. vi + 342. (Paris: Georges Carré et C. Naud, 1899.)

COFFEE in its various commercial aspects, whether from the point of view of the planter, the broker, the retail dealer, or the consumer, has from time to time commanded a great deal of attention. Occupying as it does a large and extended area of cultivation within the tropics, and being an important branch of industria culture in many of the British possessions, as Jamaica, Ceylon, Southern India, and Borneo, it is but reasonable to expect that treatises on the cultivation, best means of improvement of yield and quality, prevention of disease, &c., would be numerous. In the English language many such works are available, and if this be so, bearing on a culture which though large and important is small in comparison with that of Brazil, Central America, Mexico, Java, and Sumatra, we might also expect to find a large number of books in the languages of the nations to which these extensive coffee growing countries belong.

The work before us is the latest contribution to the French literature of the subject, and extensive as that literature is and for the most part carefully worked out, M. Lecomte's handbook will be a useful and valuable addition not only for its arrangement, but also for the concise character of the information given and the various items of intelligence regarding production in the several countries referred to and exports therefrom.

The first chapter is devoted to the early history of the coffee plant. The botany of the genus *Coffea* is treated of in the second chapter occupying twenty-five pages, and is illustrated by a figure of the so-called Arabian coffee (*Coffea arabica*) in flower and in fruit, and a figure is also given of *C. stenophylla*, the tree which furnishes the wild coffee of Sierra Leone, as well as of the new species from the Congo, *C. canephora*, Pierre. In the enumeration of species given in this chapter thirty-three are referred to, prominence, of course, being given to *C. arabica* and *C. liberica*, the two most important coffee yielding species. The best varieties of *C. arabica* cultivated in various parts of the world are also enumerated. Referring to *Coffea stenophylla* the specific name of which, by the way, is spelt with a capital initial letter, the author gives the following interesting account of it: In 1894 some plants of this new species were received at the Royal Gardens, Kew, from Sierra Leone, and these plants produced flowers in 1895. Seeds were afterwards sent to most of the English colonies where it was thought the plant might flourish. In Ceylon, however, the results have not been satisfactory; but in Dominica, Jamaica, and Trinidad, the case has been different. In the Botanic Garden of Port of Spain, Trinidad, there are some fine fruiting examples of this tree quite free of disease. The author further regrets that this coffee has not yet been introduced into the French colonies. On the climate and elevation suitable for the success of coffee plantations the great coffee-growing country of Brazil has the first consideration. The remaining chapters are devoted to the consideration of soils, the choice of seeds, transplanting, manures, shade trees, &c. The use of simple diagrams showing the different positions in which the coffee plant and its shade trees may be placed will be found useful, as will also the list of trees suitable both for shade and shelter, amongst which we notice such well-known trees as *Albizzia Lebbek*, *A. stipulata*, and *Exythrina indica.*

On the subject of harvesting or gathering the crop it is pointed out how extremely variable in the period of ripening its seeds the plant is in different countries. Thus in Cuba, Guadaloupe, and other islands of the Antilles, the harvest commences in August and is carried on through

November, while in Brazil it commences in May and ends in September.

Though the broad principles of the preparation of coffee for market are well known, the description here given, especially aided as it is by the practical illustrations, will be of especial value. No book on coffee could possibly be complete without a reference to the diseases to which the plant is subject, whether the disease belongs to the vegetable or animal kingdom. Consequently we find thirty-one pages devoted to this part of the subject. Substitutes for coffee also come under consideration. occupying, however, a comparatively small space, and though no doubt sufficient is said about them, their number might be considerably increased. Perhaps one of the most interesting parts of the book is that treating on production, in which each country is considered separately, the first chapter being devoted to the American Continent, and naturally leading off with Brazil. British, Dutch and French Guiana are also considered, and comparisons made with product and export, as are also those of Paraguay, Venezuela, Columbia, Costa Rica, Mexico and other places. The West Indies, including Jamaica, Porto Rico, Trinidad and other important coffee growing countries, as well as the Eastern countries and Africa, are also referred to. This part of the subject is practically illustrated by a map of the world, showing at a glance the geographical distribution of the coffee plant, together with the production of each country in kilogrammes, and the date to which the figures refer. A comparison of the produce of each country is readily gained by a series of disks of different sizes, with the names of the country beneath each, and the total in figures; from this it will be seen that Brazil is far ahead of any other individual country. An interesting table is also given showing the consumption of coffee in the principal countries of the world, from which it seems that of the European countries Germany consumes by far the largest quantity. The figures in tons for 1897 standing thus—Germany 136,390, France 77,310, England 12,420, while the consumption in the U.S. of America in the same year amounted to 318,170 tons. The book concludes with a table of subjects of the several chapters, but lacks that most necessary adjunct of all books—a good index.

## THE BIRDS OF SURREY.

*The Birds of Surrey.* By J. A. Bucknill. Pp. lvi + 374, illustrated. (London: R. H. Porter, 1900.)

FROM its great extent of open moorland and the presence of several large sheets of water, Surrey occupies an unusually favourable position among the metropolitan counties for the development of a large bird-fauna; and since a very considerable portion of the county is now undergoing a metamorphosis under the hands of the builder as the area of the metropolis and its suburbs increase, it is most important that a full record should be secured of the species of birds which are fast disappearing from its limits. The compiling of such records, and the careful working out of the past history of locally distributed species within the limits treated of, seem, indeed, to be the chief justification for the publication of county ornithologies. And in this respect, as well as in the careful collection of local bird-names, the author of the work before us appears to have discharged his task in a thoroughly satisfactory manner. An instance of this is afforded by his account of the occurrence of the black-grouse in Surrey. To many of our readers it will probably come as a surprise to learn that black-cock shooting was a recognised sport on the Surrey moors during the forties, and even to a considerably later date. At the present day there is, however, scarcely a single genuine wild bird of this species to be met with in the county; and the excellent history of its gradual extermination given by Mr. Bucknill should, therefore, be read with the greatest interest alike by sportsmen and by ornithologists. The raven, the buzzard, the marsh-harrier, and the dotterel are other species which have disappeared from the county, either totally or as nesting birds; the last record of the occurrence of the dotterel being 1845, when a couple of specimens were purchased from the landlord of an inn at Hindhead.

Of the numerous rare birds that have been noticed from time to time in the county, the great majority have been visitors to the well-known Frensham ponds, the larger of which extends into Hampshire. Here we are practically in Gilbert White's country; and in these favoured haunts have been seen the osprey, the spoonbill, several of the rarer kinds of duck, the goosander, and the purple heron. Sad to say, the arrival of these wanderers has for the most part been speedily followed by their slaughter; and, as the author remarks, hundreds of other avian rarities have doubtless been killed and eaten without record. Unhappily, the great increase in game preservation which has taken place of late years in the county appears to have been the cause of the diminution in the numbers of many of the rarer species of birds. But there are many country gentlemen, on the other hand, who are lovers of natural history, and who veto as much as possible the bird-slaying propensities of their gamekeepers. It is to such, and to the laws now in force for the protection of wild birds, that we have to look for the commencement of a better state of things in the wilder parts of the county. And the fact that the golden oriole and the hoopoe have been observed of late years on several occasions indicates the probability that these beautiful birds would once more nest in the Surrey groves if only they received adequate protection.

A feature of the book is the beautiful series of illustrations of Surrey scenery; the views of Frensham Great Pond and of the Surrey Weald being some of the best examples of landscape photogravure that have come under our notice. Although primarily intended for residents in the county (among whom we are glad to see that a long list of subscribers has been enrolled), the book is full of interest to all bird-lovers living in the south of England.

R. L.

## OUR BOOK SHELF.

*Untersuchungen ueber d. Vermehrung d. Laubmoose durch Brutorgane und Stecklinge.* Von Dr. Carl Correns, a.ö. Prof. d. Botanik in Tübingen. Pp. xxiv + 472; mit 187 abbild. (Jena: Verlag v. Gustav Fischer, 1899.)

FEW people perhaps fully realise how abundantly the mosses are provided with modes of vegetative reproduction, even although they may be fully cognisant of the fact that the protonema—the precursor of the moss-plant—is readily induced to make its appearance from the cut ends of the stems and leaves of these plants. Prof. Correns has done a useful service in bringing together, in a classified manner, the numerous methods employed by mosses to ensure their propagation and dispersal by means less expensive than by the production of spores. The readily friable stems of some species of *Andreaea*, the easily detached branchlets of *Dicranum*, are instances, well known to muscologists, of a large class of propagative bodies. These simpler forms of reproduction are also widely spread amongst plants other than mosses, and in some cases—e.g. *Lycopodium Selago*—the superficial resemblance is rather striking. Less obvious are the subterranean bulbils or buds, such as are met with in *Dicranella*, *Barbula*, or *Funaria*, in which special tuberous bodies are formed. *Dicranella heteromalla* affords a pretty example of a form transitional from the simple to the more complex types, inasmuch as the subterraneous bulbils of this moss are little more than rows of swollen rhizoid-cells arranged somewhat like a string of beads. Many of these bulbils are regarded by Correns rather as of the nature of food reservoirs than as brood bodies; but it is at least certain that they are in most cases able to function in the latter capacity as well as in that of mere storehouses of food-reserves.

Other and very common cases of brood bodies are afforded by the so-called "*folia fragilia*"—leaves which readily become detached from the parent plant, and with greater or less intervention of protonematal filaments give birth to new individuals. Oftentimes the leaves destined to this end undergo considerable contraction in size, and, indeed, may assume a totally rudimentary appearance.

Again, as in some species of *Orthotrichum*, cells grow out from the ends of leaves, and the sausage-shaped proliferations, after detachment from the parent plant, grow out to filaments, on which new plants arise.

The above are only a few of the many forms cited by Correns of gametophytic reproductions in the mosses by vegetative means. But as Pringsheim long ago pointed out, it is also possible to reproduce these plants from the sporophyte generation, especially from cut fragments of the seta or stalk of the moss-capsule. These are far more interesting, as they resemble the curious aposporic development met with in a number of ferns. Indeed, these latter offer, perhaps, a means of attacking the details of the phenomena of apospory with a greater chance of success than in the case of the ferns, since they seem more easily induced by simpler experimental devices than is the case with the higher plants.

A general synopsis of the various types and forms of brood-bodies forms a useful adjunct to the main descriptive part of a book on which the author has evidently expended much labour, and which should earn for him the gratitude of all those muscologists who are not merely describers of species, as well as of botanists who seem too often rather to be disposed to ignore an important section of the vegetable kingdom.

*Village Notes, and Some Other Papers.* By Pamela Tennant. Pp. xii + 204; 13 plates. (London: William Heinemann, 1900.)

THESE notes reveal some of the humour and pathos of rural life in South Wilts, and here and there they lightly touch natural scenes and objects other than human. The plates, which are reproductions from original photographs of Wiltshire views, are excellent, and the book itself is a dainty volume suitable for a drawing-room table. Reference is made to the "pernicious habit of 'underlining' in their letters" which some people adopt, yet we notice an abundance of italicised words in the book, and they are equivalent to the underlined words so severely condemned.

## LETTERS TO THE EDITOR.

### The Conductivity produced in Gases by the Motion of Negatively-charged Ions.

RECENT researches have shown that gases are rendered conductors of electricity when negatively-charged ions move through them with a high velocity. Thus the kathode rays and the Lenard rays possess the property of ionising gases through which they pass (J. J. Thomson, "The Discharge of Electricity through Gases"). Becquerel (*Comptes rendus*, March 26, 1900) also has recently shown that the conductivity produced by radium is due to small negatively-charged particles given off by the radio-active substance. In these cases the charged particles which ionise the gas move with velocities nearly equal to the velocity of light.

Some experiments which I have recently made show that ions which are produced in air by the action of Röntgen rays will produce other ions when they move through the gas with a velocity which is small compared with the velocity of light.

When Röntgen rays are sent through a gas, at atmospheric pressure, the current between two electrodes immersed in the gas increases in proportion to the electric force, when the force is small. For large forces the current attains a value which is practically constant.

When the pressure of the gas is reduced, the connection between conductivity and electromotive force is more complicated. The accompanying tables show the connection between current and electric force for air at 2 and ·8 mm. pressure. At these pressures the current is practically constant for forces of about 10 volts per centimetre, and when forces of this order are acting, all the ions are produced directly by the rays. When the electric force is increased these ions produce others, so that the current again increases.

It appears from the following investigation that the new ions are produced by the collisions between negatively-charged ions and the molecules of the gas.

Let us suppose that $n$ negative ions are moving in a gas between two parallel plates at a distance $d$ apart. Let X be the electric force between the plates $\left(=\frac{V_1 - V_2}{d}\right)$, and $p$ the pressure of the gas. In going a distance $dx$ the $n$ ions produce $\alpha \times n \times dx$ others, where $\alpha$ is a constant depending on X, $p$, and the temperature, which is constant in these experiments. (The coefficient $\alpha$ is practically zero for small values of X, unless $p$ is also small).

$$\therefore \quad dn = \alpha n dx$$
$$\text{and } n = n_0 E^{\alpha x}$$

Hence $n_0$ ions starting at a distance $x$ from one of the plates will give rise to $n_0(E^{\alpha x} - 1)$ others. When the ions arrive at the plate, the formation of new ions ceases and the current stops, although the electromotive force is kept on. Let $n_0$ be the number per unit volume produced by the rays. The total number of ions produced will therefore be

$$\int_0^d n_0 E^{\alpha x} dx = \frac{n_0}{\alpha}(E^{\alpha d} - 1)$$

per unit area, $n_0 d$ being the number produced by the rays. Hence

$$\frac{c}{c_0} = \frac{1}{\alpha d}(E^{\alpha d} - 1)$$

where $c$ is the current for a large force X, and $c_0$ the current composed of ions produced by the rays.

The following experiments were made in order to test the accuracy of this formula for currents produced between two parallel plates whose distance apart could be varied.

The rays fell normally on one of the plates, which was made of thin aluminium, and after passing through the air between the plates, the rays were completely stopped by the second plate, which was of brass. The plates were 10 centimetres in diameter, and the rays were allowed to fall on a circular area at the centre 4 centimetres in diameter. The conductivity was thus confined to a region where the force was constant. A large part of the conductivity ($c_0$) arises from the secondary radiation from the brass disc. At high pressures the secondary effect is principally confined to a layer of gas near the surface (John S. Townsend, *Camb. Phil. Proc.*, vol. x. Part iv.), but when the pressure is low the secondary rays are not so rapidly absorbed by the gas, and the ionisation ($n_0$) between the plates is nearly uniform.

The ratios of $\frac{c}{c_0}$ were determined for different forces, the air being at a pressure of two millimetres. When the strength of the rays was reduced to $\frac{1}{3}$ of its original value it was found that the ratios $\frac{c}{c_0}$ were unaltered. This shows that $\alpha$ is independent of $n_0$ and is some function of X and $p$.

The plates were then set at one centimetre apart, and the values of $c$ were determined for different forces. The results, corresponding to a pressure 2 and ·8 mm., are given in the second columns of the accompanying tables. The numbers given are the mean between the currents in opposite directions. With this form of apparatus, however, there were only very small differences found in the conductivity when the electromotive forces were reversed. The plates were then set at two centimetres apart, and the currents found in this case for pressures 2·14 and ·8 mm. are given in the third columns of the tables.

The force X is given in volts per centimetre.

TABLE I.—*Air at pressure 2 mm.*

| X | $c(d=1)$ | $c(d=2)$ | Calculated values of $c(d=1)$ |
|---|---|---|---|
| 20 | 28 | 49·5 | 28 |
| 40 | 28·2 | 51 | 28·4 |
| 80 | 29·5 | 55 | 29·5 |
| 120 | 36 | 81 | 35·5 |
| 160 | 51 | 173 | 50 |
| 180 | 64·5 | 293 | 63 |

TABLE II.—*Air at pressure ·8 mm.*

| X | $c(d=1)$ | $c(d=2)$ | Calculated values of $c(d=1)$ |
|---|---|---|---|
| 10 | 10 | 17·7 | 10 |
| 20 | 10·5 | 19 | 10·5 |
| 40 | 12 | 24·5 | 12 |
| 80 | 17 | 53·5 | 17 |
| 120 | 31 | 190 | 29 |
| 165 | 61 | 990 | 62·5 |
| 186 | 82 | 2180 | 84 |

The tables show that the current increases more rapidly with X when the plates are two centimetres apart than when they are one centimetre apart. This effect cannot be attributed to a surface action which would be independent of $d$ when X remains constant.

From the formula $\frac{c}{c_0}=\frac{1}{\alpha d}\left(E^{\alpha d}-1\right)$ we can deduce the values of $\alpha$ from the third columns of the tables, by making $d=2$ and $c_0$ the smallest value of $c$. From values of $\alpha$ thus obtained, the ratios $\frac{c}{c_0}$ for the different forces corresponding to plates 1 centimetre ($d=1$) were calculated. The values of $c$ found in this manner are given in the fourth columns, and they show a good agreement with the experimental determinations.

Other experiments for different pressures have also been made, and they all show an agreement with the present theory.

For the purpose of deciding whether it is the positive or negative ions which produce other ions by their rapid motion through the gas, we may mention the following experimental results. When the lines of force in the gas are not parallel, large differences in current were obtained on reversing the electromotive force. Thus, when the conductivity takes place between two electrodes one inside the other, it was found that for high electromotive forces the current is much greater when the ions go towards the inner electrode.

Thus, with an apparatus consisting of a small spherical electrode surrounded by a large electrode made of thin aluminium, the currents, when the outside electrode was positive, were 14 for a potential difference of 40 volts, and 34 for a potential difference of 300 volts; when the outside electrode was negative the currents were 14 and 174 for the same voltages. In these experiments the pressure was about 2 mm. The positive and negative ions produced by the rays are generated nearly uniformly throughout the area between the electrodes. When the large electrode is positive only a few of the negative ions pass through the region round the small electrode where the force is big, and the current only increases from 14 to 34. When the electromotive force is reversed all the negative ions produced by the rays come into the region where the force is big, and the current is thereby increased from 14 to 174. It is therefore evident that the increase of conductivity must be attributed to the rapid motion of the negative ions.

I hope in a future paper to give a fuller account of the above experiments, and also to point out some of the applications of this theory to the passage of electricity through gases. I may mention that the high conductivities obtained with ultra-violet light (Stoletow, *Journal de Physique* (2), 9, pp. 463–473, 1890), at pressures of about 1 millimetre, may be explained by this theory.

Approximate values of the energy of translation of the negative ion when producing another ion by a collision can also be obtained from the coefficients $\alpha$. J. S. TOWNSEND.

Trinity College, Cambridge.

## A Remarkable Hailstorm.

I HEREWITH enclose you prints, from untouched negatives, of hailstones which fell at Northampton on Friday, July 20.

The drawing board measures 19½″ by 17″, and the average circumference of the hailstones upwards of five inches. These are by no means the largest that fell, according to the statements of trustworthy persons, but were typical of what fell in my garden.

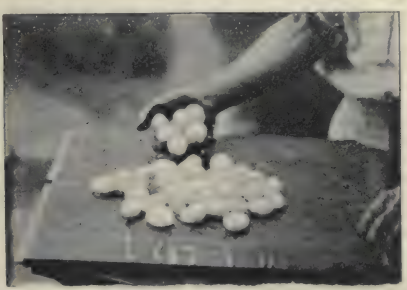

FIG. 1.—Group of hailstones which fell at Northampton on July 20. Size of board 19½ in. by 17 in.

The majority of the stones were somewhat flattened, as shown in the front of the photograph, but many were nearly spherical like those in my hand (Fig. 1).

The stones were extremely dense and well frozen, and buried themselves in the garden soil. Where they fell on hard surfaces, they usually broke into fragments which rebounded to considerable heights, while glass roofs suffered enormous damage all over the area, some twelve miles by six, covered by the storm. I have a piece of glass 5/16ths of an inch in thickness many hundred square feet of which were broken at the various factories in the town.

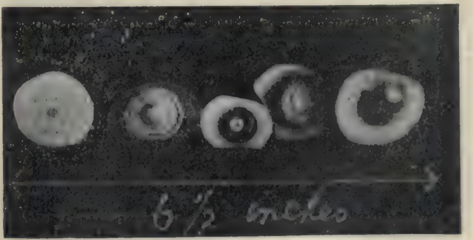

FIG. 2.—Sections of hailstones (Northampton, July 20).

The sections (Fig. 2) were an afterthought and show the structure exceptionally well in two instances.

J. G. ROBERTS.

Northampton and County School, July 30.

## *THE PHOTOGRAPHY OF SOUND-WAVES AND THE DEMONSTRATION OF THE EVOLUTIONS OF REFLECTED WAVE-FRONTS WITH THE CINEMATOGRAPH.*

### *Introduction.*

IN a paper published in the *Philosophical Magazine* for August 1899, I gave an account of some experiments on the photography of sound-waves, and their application in the teaching of optical phenomena. Since writing this paper I have extended the work somewhat and at a meeting of the Royal Society on February 15, 1900, gave an account of this work, and demonstrated certain features of wave motion with the cinematograph.

In the present article I propose to give a somewhat more extended account of the work, paying especial attention to the analogies between the sound-waves and waves of light.

In teaching the subject of optics we are obliged to resort to diagrams when dealing with the wave-front, and in spite of all that we can do, the student is apt to form the opinion that the rays are the actual entities, and that wave-fronts are after all merely conceptions.

The set of photographs illustrating this article will, I think, be of no small use to teachers in ridding the minds of students of the obnoxious rays, and impressing the fact that all of the common phenomena of reflection, refraction and diffraction are due simply to changes wrought on the wave-front.

Sound-waves in air were first observed and studied by Toepler, by means of an exceedingly sensitive optical contrivance for rendering visible minute changes in the optical density of substances. A very full description of the device will be found in Toepler's article (*Wied. Annalen*, cxxxi.), while a brief account of it will be given presently.

The waves in question are the single pulses of condensed air given out by electric sparks. A train of waves would complicate matters too much, and for illustrating the optical phenomena which we are to take up would be useless.

The snap of the spark gives us just what we require, namely, a single wave-front, in which the condensation is considerable.

When seen subjectively, as was the case in Toepler's experiments, the wave-fronts, if at all complicated, as they often are, cannot be studied to advantage, as they are illuminated for an instant only, and appear in rapid succession in different parts of the field. By the aid of photography a permanent record of the forms can be obtained and studied at leisure. The first series of photographs, published in the *Philosophical Magazine*, were made with an apparatus similar to the one to be presently described; while most of those illustrating this article were made on a much larger scale by employing a large silvered mirror in place of the lens, an improvement due to Prof. Mach, of Prague, who has given much attention to the subject.

As it is a matter of no trouble at all to set up in a few minutes, in any physical laboratory, an apparatus for showing the air-waves subjectively, and as the method does not seem to be as well known as it deserves to be, a brief description of the "Schlieren" apparatus, as Toepler named it, may not be out of place.

### *The Apparatus.*

The general arrangement of the "Schlieren" apparatus is shown in Fig. 1. A good-sized achromatic lens of the finest quality obtainable, and of rather long focus, is the most important part of the device. I have been using the object-glass of a small telescope figured by the late Alvan Clarke. Its diameter is five inches, and the focal length about six feet. I have no doubt but that a smaller lens could be used for viewing the waves, but one of at least this size is desirable for photographing them.

The lens is mounted in front of a suitable source of light (in the present case an electric spark), which should be at such a distance that its image on the other side of the lens is at a distance of about fifteen feet.

The image of the spark, which we will suppose to be straight, horizontal, and very narrow, is about two-thirds covered with a horizontal diaphragm (*a*), and immediately behind this is placed the viewing-telescope. On looking into the telescope we see the field of the lens uniformly illuminated by the light that passes under the diaphragm, since every part of the image of the spark receives light from the whole lens. If the diaphragm be lowered the field will darken, if it be raised the illumination will be increased. In general it is best to have the diaphragm so adjusted that the lens is quite feebly illuminated, though this is not true for photographic work. Let us now suppose that there is a globular mass of air in front of the lens of slightly greater optical density than the surrounding air (*b*). The rays of light going through the upper portion of this denser mass will be bent down, and will form an image of the spark below the diaphragm, allowing more light to enter the telescope from this particular part of the field; consequently, on looking into the instrument, we shall see the upper portion of the globular mass of air brighter than the rest of the field. The rays which traverse the under part of "*b*," however, will be bent up on the contrary, forming an image of the spark higher up, and wholly covered by the diaphragm; consequently this part of the field will appear black. It will be readily understood that, with the long path between the lens and the image a very slight change in the optical density of any portion of the medium in front of the lens will be sufficient to raise or depress the image above or below the edge of the diaphragm, and will consequently make itself manifest in the telescope.

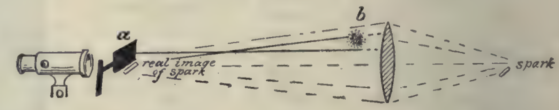

FIG. 1.

The importance of using a lens of first-class quality is quite apparent, since variations in the density of the glass of the lens will act in the same way as variations in the density of the medium before it, and produce unequal illumination of the field. It is impossible to find a lens which will give an absolute even, feeble illumination, but a good achromatic telescope objective is perfect enough for every purpose. A more complete discussion of the operation of the apparatus will be found in Toepler's original paper in the *Annalen*. The sound-waves, which are regions of condensation, and consequent greater optical density, make themselves apparent in the same way as the globular mass of air already referred to. They must be illuminated by a flash of exceedingly short duration, which must occur while the wave is in the field of view.

Toepler showed that this could be done by starting the sound-wave with an electric spark, and illuminating it with the flash of a second spark occurring a moment later, while the wave was still in the field. A diagram of the apparatus used is shown in Fig. 2. In front of the lens are two brass balls (*a*, *a*), between which the spark of an induction coil passes, immediately charging the Leyden-jar *c*, which discharges across the gap at *e* an instant later. The capacity of the jar is so regulated that the interval between the two sparks is about one ten-thousandth of a second. The field of the lens is thus illuminated by the flash of the second spark before the sound-wave started by the first spark has gone beyond the edge of the lens.

To secure the proper time-interval between the two sparks it is necessary that the capacity of the jar be quite small. A good-sized test tube half full of mercury standing in a jar of mercury is the easiest arrangement to fit up. This limits the length and brilliancy of the illuminating-spark, and with the device employed by Toepler I was unable to get enough light to secure photographs of the waves. After some experimenting I found that if the spark of the jar was passed between two thin pieces of magnesium ribbon pressed between two pieces of thick plate-glass, a very marked improvement resulted. With this form of illuminator I found that five or six times as much light could be obtained as by the old method of passing the spark between two brass balls.

The spark is flattened out into a band, and is kept always in the same plane, the light issuing in a thin sheet from between the plates. By this arrangement we secure a light source of considerable length, great intensity, and bounded by straight edges, the three essentials for securing good results. The glass plates, with the ribbon terminals between them, must be clamped in some sort of a holder and directed so that the thin sheet of light strikes the lens: this can be accomplished by darkening the room, fastening a sheet of paper in front of the lens, and then adjusting the plates so that the paper is illuminated as much as possible. The image formed by the lens will be found to have very sharp straight edges,[1] on one of which the edge of the diaphragm can be set in such a manner as to allow but very little light to pass when the intervening medium is homogeneous; a very slight change, however, in any portion may be sufficient to cause the entire amount of light passing through that portion to pass below the diaphragm and enter the telescope.

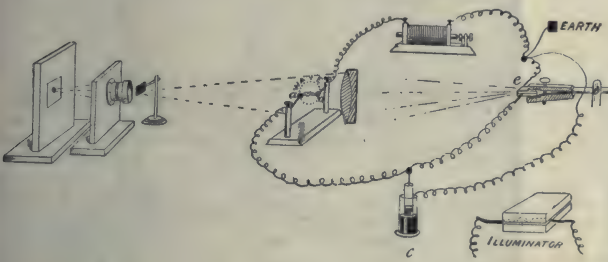

FIG. 2.

The photographs were made by substituting a photographic objective for the telescope, in the focal plane of which a vertical board was mounted to support the plate. The room was darkened, a plate held in position, and a single spark made to pass between the knobs by pulling a string connected with the hammer of the induction coil. The plate was then moved a trifle and a second impression secured in the same way. This obviated several of the difficulties experienced in the earlier work. The images never overlapped, and the hot air from the spark did not appear in the pictures. About thirty-five images were obtained on each plate in less than a minute, from which it was usually possible to pick a series showing the wave in all stages of its development, owing to the variations in the time-interval between the two sparks.

In the first series the pictures were so small that it was necessary to enlarge them several diameters. Those of the new series, owing to the use of an eight-inch mirror in place of the five-inch lens, and an objective of larger aperture and longer focus, required no enlarging.

### *The Wave-Front Photographs.*

In the study of optics we may treat the subject of regular reflection in two ways, by rays and by wave-fronts. When spherical waves of light are reflected from a plane surface, we know that the reflected waves are also spherical in form, the centre of curvature being a point just as far beneath the reflecting surface as the source of light is above it. In the first of the series of photographs we have the reflection of a spherical wave of sound by a flat plate of glass, the wave appearing as a circle of light and shade surrounding the image of the balls between which the spark passed (Fig. 3). The reflected wave or echo from the plate is seen to be spherical, with a curvature similar to the incident wave.

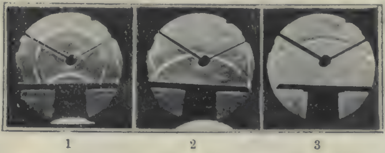

FIG. 3.

When we have a source of light in the focus of a parabolic mirror, the rays leave the mirror's surface parallel to one another, and move out in an intense narrow beam. Treating this case from the wave-front point of view, we ascertain by the usual geometrical construction that the spherical wave is changed by reflection into a plane or flat wave which moves out of the mirror without further divergence. In the picture (Fig. 4), only a portion of the parabolic reflector is shown near the bottom. The sound-wave starts in the focus, and the reflected portion appears quite flat.[1]

What happens now if we use a spherical mirror in the same way?

Owing to the spherical aberration the reflected rays are not strictly parallel, or the reflected wave is not a true plane. Let us start a sound-wave in the focus of such a mirror, and follow the reflected portion out of the mirror (Fig. 5). We notice that near the axis of the mirror the effect is much the same as in the case of the parabola, that is, the reflected front is plane. Thus we are

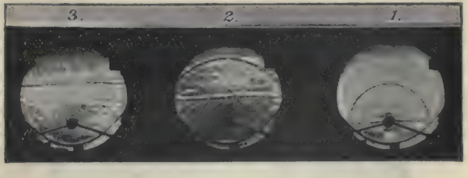

FIG. 4.

---

[1] If more than one image appears it means that the plane of the glass plates of the illuminator does not lie parallel to the optical axis of the system. It is of prime importance to secure a single image.

[1] In this series and some others left and right have been inadvertently interchanged by the engraver. The series should be followed by the numbers.

accustomed to say that if we confine ourselves to a small area around the axis, a mirror of spherical form acts almost as well as a parabola. If on the contrary we consider the reflection from the entire hemisphere, we see that the reflected wave curls up at the edges, having a form not unlike a flat-bottomed saucer. The flat bottom moves straight up, travelling everywhere normal to its surface; but the curled up edges converge inwards, coming to a focus in the form of a ring around the flat bottom. This ring, of course, does not show in the photograph, which is a sectional view, but it will be seen that in one of the views (No. 4) the curved edge has disappeared entirely. In reality it is passing through a ring focus, and presently it will appear again on the other side of the focus, curved the other way, of course, and trailing along after the flat bottom. This curious evolution of the wave can be shown by geometrical construction, and I shall show later how its development can be shown with the cinematograph.

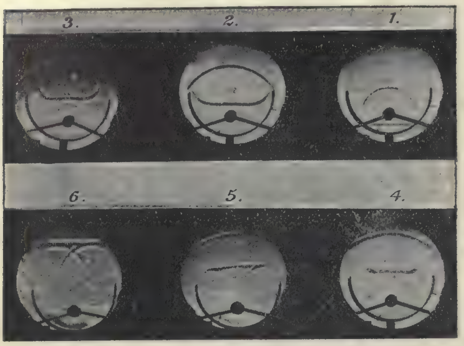

FIG. 5.

When the spherical waves start in one focus of an elliptical mirror, they are transformed by reflection into converging spheres, which shrink to a point at the other focus, the surface being aplanatic for rays issuing from a point. An elliptical mirror was made by bending a strip (Fig. 6) of metal into the required form, and a sound-wave started at one of the foci. The transformation of the diverging into a converging sphere, and the shrinkage of the latter to a point at the other focus, is well shown (Fig. 6).

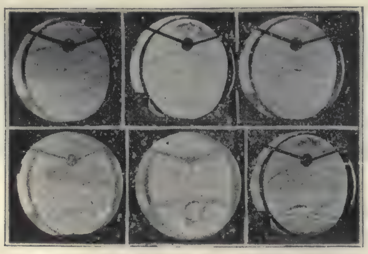

FIG. 6.

We will consider next another case of spherical aberration. When parallel rays of light enter a concave mirror, those reflected from points of the mirror near its axis converge approximately to a point situated halfway between the surface of the mirror and its centre of curvature. The wave-front in the case of parallel rays is, of course, plane, and is changed by reflection into a converging shell of approximately spherical curvature. If we investigate the case more carefully, we find, however, that the reflected rays do not come accurately to a focus, but envelope a surface known as the caustic—in this case an epicycloid. The connection between the wave-front and the caustic is perhaps not at once apparent. Let us examine the changes wrought on a sound-wave entering a concave hemispherical mirror (Fig. 7).

If we follow the wave during its entrance into the mirror, we see that the reflected portion trails along behind, being united to the unreflected part at the mirror's surface. After the reflection is complete, we find the reflected wave of a form not unlike a volcanic cone with a large bowl-shaped crater (No. 4). This bowl-shaped portion we may regard as a converging shell, which shrinks to point at the focus of the mirror. As it shrinks, the steep sides of the cone run in under the bowl, crossing at about the moment when the converging portion is passing through the focus (No. 6). The rim of the crater forms a cusp on the wave-front, and if we follow this cusp we shall see that it traces the caustic surface. Hence we may define the caustic as the surface traced by the cusp of the wave-front.

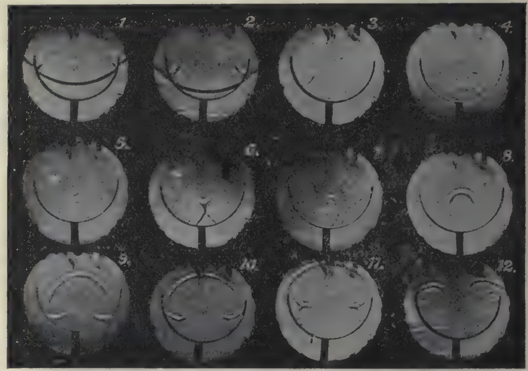

FIG 7.

The portion of the wave which comes to a focus at once begins to diverge again, uniting with the sides of the crater, the whole moving out of the mirror in a form somewhat resembling a mushroom or the bell of a Medusa jelly-fish. The turned-under edges of the bell are cusped, and these cusps trace the caustic enveloped by the twice-reflected rays. These forms can also be constructed geometrically.

A much more complicated case is now shown (Fig. 8). Here the wave starts within a complete sphere, or rather cylinder. (Cylindrical surfaces have been used in all these cases for obvious reasons, the sectional views shown in the photographs being the same for both forms of surface.) Starting in the principal focus of the closed mirror, the wave is bounced back and forth, becoming more complicated after each reflection, yet always symmetrical about the axis. Only a few of the many forms are shown, and, with the exception of the first three or four, are not arranged in order; for at the time that the series was arranged on the slide this case had not been worked out geometrically, and it was quite impossible to determine the evolution of the different forms. More recently this case has been constructed for five reflections, and all of the forms shown in the photographs found.

We will take up next some cases of refraction, the first being that of a spherical wave at a flat surface of a denser medium. In Fig. 9 we have a rectangular tank with sides made of plane-parallel glass, and covered with a collodion film of soap-bubble thickness made by the method described by Toepler. Ordinary collodion is diluted with about ten parts of ether, poured on a small piece of plate-glass and immediately drained off. As soon as it is quite dry, a rectangle is cut with a sharp knife on the film. Toepler's method of removing the film was to place a drop of water on one of the cuts, and allow it to run in by capillarity; but I have had better success by proceeding in the following manner:—One end of the plate is lowered into a shallow dish of water, and the plate inclined until the water comes up to one of the cuts. By looking at the reflexion of a window in the water, it is possible to see whether the film commences to detach itself from the glass. If all goes well, it will float off on the surface of the water along the line of the knife-cut, and it should be slowly lowered (one end resting on the bottom of the dish) unti the rectangular piece detaches itself and floats freely on the surface. The edges of the tank are well greased, and then lowered carefully upon the film, to which they will adhere. The whole must then be lifted from the water in an oblique direction, when the film will be found covering the tank and exhibiting the most beautiful interference-colours. The tank was filled with carbonic acid and placed under the origin of the sound-wave. On striking the collodion film, the wave is partly reflected and partly transmitted, and it will be seen that the reflected component in air has moved farther than the transmitted component in the carbonic acid. The spherical wave-front is transformed into an hyperboloid on entering the denser medium. This is well shown in No. 3 of the series. In No. 4 the wave is seen in air, having been reflected up from the bottom of the tank.

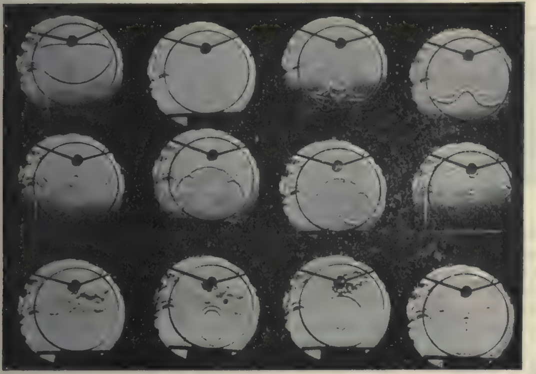

FIG. 8.

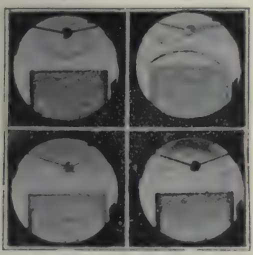

FIG. 9.

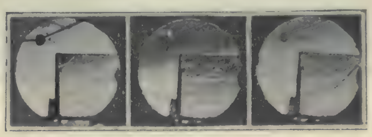

FIG. 10.

In Fig. 10 we have the refraction of the wave in the same tank under oblique incidence. The bending of the wave within the tank is very marked. The wave-fronts reflected from the side which follows the unreflected portion is also interesting in connection with Lloyd's single mirror interference experiment (No. 2 of series).

After several failures I succeeded in constructing a prism with its two refracting faces of this exceedingly thin collodion, which, when filled with carbonic acid, showed the bending of the wave-front, exactly as we figure it in diagrams for light. It was necessary to have the collodion thinner than before, since if we are to photograph the wave after twice traversing the film, we must lose as little energy as possible by reflexion.

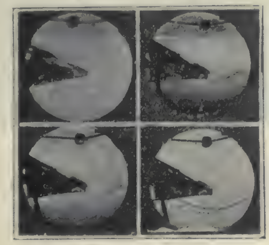

FIG. 11

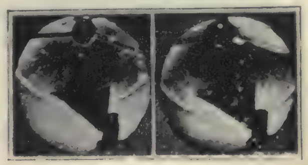

FIG. 12.

Fig. 11 shows the refraction in a carbonic acid prism, the bending being particularly noticeable in No. 4, on which I have, with a pair of dividers, traced out the position which the wave-front would have occupied had it not traversed the prism.

The bending of the wave-front in the opposite direction is shown in Fig. 12, where the same prism is filled with hydrogen gas, in which sound travels faster than in air.

In the next figure we have a very interesting case, though, owing to the experimental difficulties, the photographs are not quite as satisfactory as some of the others. It represents the transformation of a spherical into a plane wave by passage through a double convex lens.

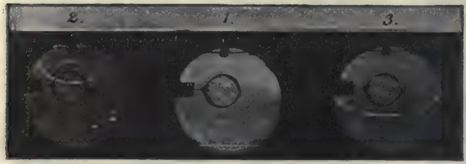

FIG. 13.

The construction of the cylindrical lens of exceedingly thin collodion was a matter of great difficulty. The flat, circular ends were made of thin mica as free from striæ as possible, that the passage of the wave through the lens could be followed. On these discs the collodion film was wound, the whole forming a hollow drum, which was then filled with carbonic acid. The sound-wave, started at the principal focus of this lens, is seen to be quite flat after its emergence (Fig. 13).

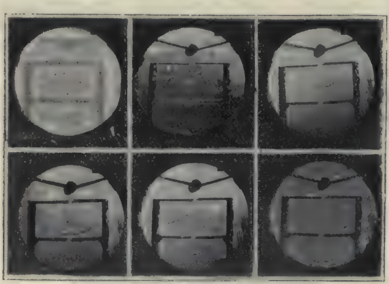

FIG. 14.

We will next take up some cases of diffraction, beginning with the well-known principle of Huygens, that any small portion of a wave-front can be considered as the centre of a secondary disturbance, and that a small portion of this secondary disturbance can act as a new centre in its turn.

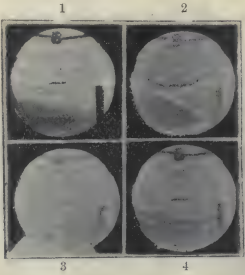

FIG. 15.

In Fig. 14 we have the wave starting above a plate with a narrow slit in it. This slit is seen to be the centre of a secondary hemicylindrical wave which moves down precisely as if the spark were located at the slit. After proceeding a short distance this secondary wave encounters a second slit, and the same thing happens as before, the little slice that gets through spreading out into a complete wave, while the intercepted portion bounces back and forth between the plates.

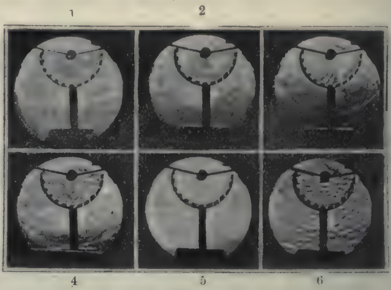

FIG. 16.

Fig. 15 shows the very limited extent to which sound shadows are formed. The wave is intercepted by a small glass plate. Just below the plate in No. 3 of the series a gap in the wave is found, which constitutes a shadow. But presently, by diffraction, the wave curls in, closing up the gap and obliterating the shadow entirely. In the last one of the series it is interesting to note how the diffracted waves have their centres at the edges of the obstacle, the edges acting as secondary sources, as in the case of the diffraction of light.

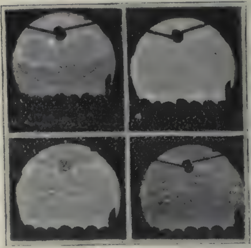

FIG. 17.

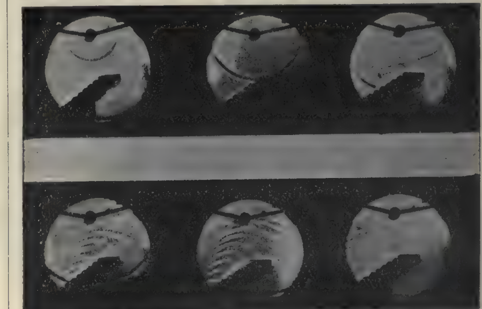

FIG. 18.

The passage of a wave through a diffraction grating is shown in Fig. 16. The grating is made of strips of glass arranged on a cylindrical surface, the wave starting at the centre of curvature. In No. 2 of the series the union of the secondary disturbances coming from the openings into a new wave-front is beautifully shown. In No. 3 the reflected wavelets have converged to the centre, but as each one is a complete hemicylinder, we see them radiating from the centre. This form can be constructed by describing semicircles around points on a circle of such radius that they all pass through the circle's centre. These semicircles represent secondary wavelets starting simultaneously from the various grating elements. In the last three pictures of the series the wave passes down, strikes the table, and is reflected up again, and it is interesting to see how the medium is broken up into meshes by the crossing and recrossing of the secondary waves.

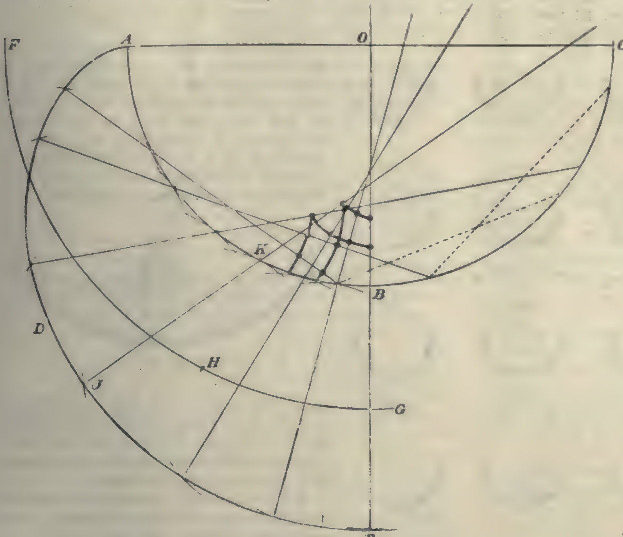

FIG. 19.

Fig. 17 shows the form of the secondary wavelets formed by the reflection of a wave from a corrugated surface, and is interesting in connection with reflection gratings.

The formation of a musical note by the reflection of a single pulse from a flight of steps is shown photographed in Fig. 18. This phenomenon is often noticed on a still night when walking on a stone pavement alongside a picket-fence, the sound of each footstep being reflected from the pailings as a metallic squeak, which Young has pointed out to be analogous to the power of a diffraction grating to construct light of a definite wave-length.

It occurred to me, while making some geometrical constructions to aid in unravelling some of the complicated forms reflected from surfaces of circular curvature, that a very vivid idea of how these curious wave-fronts are derived one from another could be obtained if a complete series could be prepared on the film of a cinematograph, and projected in motion on a screen.

Having been unable to so control the time-interval between the two sparks that a progressive series could be taken, I adopted the simpler method of making a large number of geometrical constructions, and then photographing them on a cinematograph film.

As a very large number of drawings (100 or so) must be made if the result is to be at all satisfactory, a method is desirable that will reduce the labour to a minimum. I may be permitted to give, as an instance, the method that I devised for building the series illustrating the reflection of a plane wave in a spherical mirror. The construction is shown in Fig. 19.

ABC is the mirror, AOC the plane wave. Around points on ABC as centres describe circles tangent to the wave. These circles will be enveloped by another surface, ADE, below the mirror (the orthogonal surface). If we erect normals on this surface, we have the reflected rays, and if we measure off equal distances on the normals, we have the reflected wave-front. By drawing the orthogonal surface we avoid the complication of having to measure off the distances around a corner. The orthogonal surface is an epicycloid formed by the rolling of a circle of a diameter equal to the radius of curvature of the mirror on the mirror's surface, and normals can be erected by drawing the arc FG (the path of the centre of

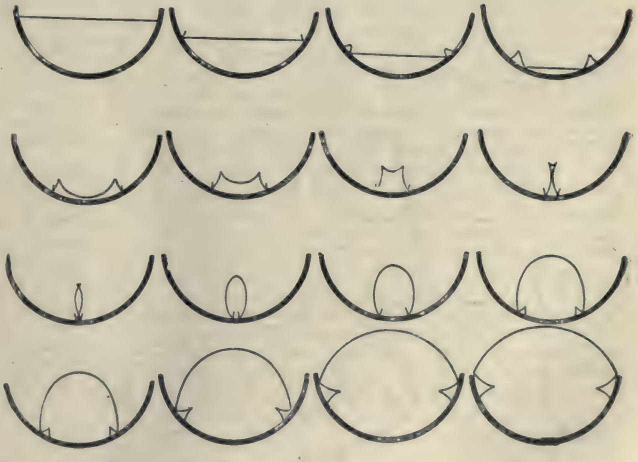

FIG. 20.

the generating circle), and describing circles of diameter BE around various points on it. A line joining the point of intersection of one of these circles with the epicycloid, and the point of tangency with the mirror, will, when produced, give a reflected ray; for example, JK produced for circle described around H. The construction once

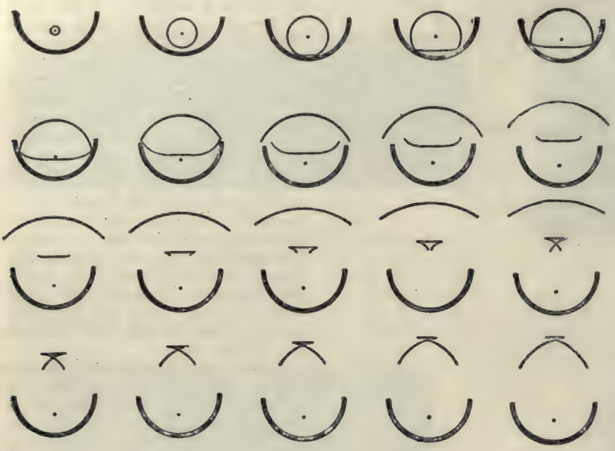

FIG. 21.

prepared, the series of wave-front pictures can be very quickly made. Three or four sheets of paper are laid under the construction, and holes are punched through the pile by means of a pin, at equal distances along each ray (measured from the orthogonal surface).

The centre of the mirror and the point where its axis

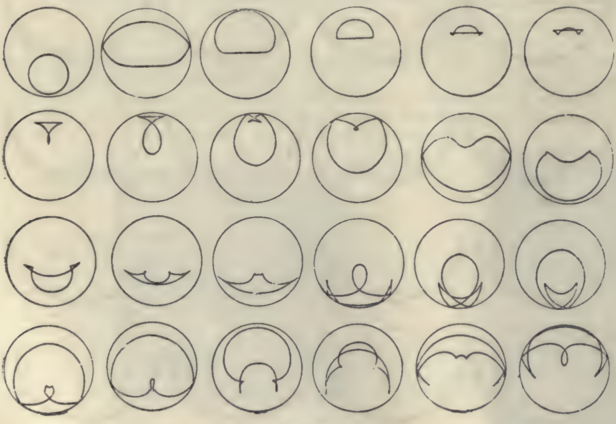

FIG. 22.

meets the surface are also indicated in the same manner. The sheets are now separated, and corresponding pinholes are united on each sheet by a broad black line, which represents the wave-front. After a time it becomes necessary to consider double reflections, and to do this we are compelled to construct twice-reflected rays (indicated by dotted lines), and measure around a corner each time.

About a hundred pictures are prepared for each series, and the pictures then photographed separately on the film, which, when run through the animatograph, give a very vivid representation of the motion of the wave-front.

Three films have been prepared thus far—reflection of a wave entering a concave hemispherical mirror (Fig. 20); reflection of a spherical wave starting in the principal focus of a concave hemispherical mirror (Fig. 21); and the reflection of a similar wave within a *complete* spherical mirror (Fig. 22). A number of these constructions, taken at intervals along the film, are reproduced, and comparison of them with the actual photographs shows the close agreement between the calculated forms and those actually obtained.

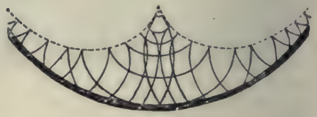

FIG. 23.

I have already mentioned the fact that the cusps on the wave-fronts trace out the caustic surfaces. This is beautifully shown in Figs. 23 and 24, where the successive fronts are seen superposed. The former is for the reflection of a plane wave in a spherical mirror, the latter for the reflection of a spherical wave starting at the focus of a similar mirror. The caustic curve is shown by a dotted line in Fig. 23, and is seen to be traced by the cusps on the wave-fronts. The construction shows that there is a concentration of energy at the cusp; consequently we may define the cusp as a moving focus, and the caustic as the surface traced by it. Though I hesitate in claiming that this relation, at once so apparent, is at all novel, I may say that, so far as I have been able to find, it is not brought out in any of the text-books, caustic surfaces being invariably treated by *ray* rather than by *wave-front* methods.

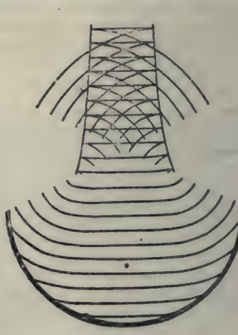

FIG. 24.

The cinematograph series illustrating reflection inside a complete sphere was the most difficult to prepare, as several reflections had to be considered. It has been completed for three reflections, and Mr. Max Mason, of Madison, to whom I am greatly indebted for his patient work in assisting me, is going on with the series. As will be seen, the wave has already become quite complicated, and it will be interesting to see what further changes result after three or four more reflections. I am also under obligations to Prof. A. B. Porter, of Chicago, who prepared the set of drawings illustrating the passage of a wave out from the principal focus of a hemispherical mirror.

R. W. WOOD.

## NOTES.

MANY friends and admirers of the late Sir William Flower will be glad to know that a committee has been formed, with Lord Avebury as chairman, to secure the erection of a memorial to him. It is proposed that the memorial shall consist of a bust and a commemorative brass tablet to be placed in the Whale Room of the Natural History Museum—one of the departments in which he was most interested, and to which he devoted special care and attention. There should be a ready response to the invitation for subscriptions to carry out this scheme, for Sir William Flower's services to science are appreciated by every one interested in the extension of natural knowledge. The Natural History Museum ought not, indeed, to be without a memorial of the man who took such an active part in its development. Subscriptions (which must not exceed two guineas) should be paid to Dr. P. L. Sclater, treasurer of the Flower Memorial Fund, 3, Hanover Square, W.

IN the House of Commons on Tuesday, Mr. Goschen gave some particulars with regard to the Committee to inquire into the boilers of her Majesty's ships. The Committee will consist of seven members, and the president will be Vice-Admiral Sir Compton Domvile. The other members of the Committee already chosen are Mr. List, superintending engineer of the Castle Company; Mr. Bain, superintending engineer of the Cunard Line; Mr. Milton, chief engineer surveyor of Lloyd's Registry of Shipping; Prof. Kennedy, formerly professor of engineering at University College; and, sixthly, an engineer of the Royal Navy holding the rank of an inspector of machinery. The seventh member of the Committee has not yet been selected. The instructions to the Committee are:—To ascertain practically and experimentally the relative advantages and disadvantages of the Belleville boiler for naval purposes as compared with the cylindrical boiler. To investigate the causes of the defects which have occurred in these boilers and in the machinery of ships fitted with them, and to report how far they are preventable either by modifications of details or by difference of treatment, or how far they are inherent in the system. Also to report generally on the suitability of the propelling and auxiliary machinery fitted in recent war vessels, and to offer any suggestions for improvement, stating at the same time the effect as regards weight and space of any alterations proposed. To report on the advantages and disadvantages of the Niclausse and Babcock and Wilcox boilers compared with the Belleville, as far as the means at the disposal of the Committee permit, and also to report whether any other description of boiler has sufficient advantages over the Belleville or the other two types mentioned, as a boiler for large cruisers and battleships, to make it advisable to fit it in any of her Majesty's ships for trial. For the purpose of making direct experiments between ships fitted with Belleville and cylindrical boilers respectively, the *Hyacinth*, fitted with Belleville boilers, will be placed at the disposal of the Committee. A cruiser of similar type fitted with cylindrical boilers will also be placed at the disposal of the Committee when required for the purpose of comparison. Mr. Goschen added that it is particularly desired that any conclusions the Committee may arrive at should be supported by experimental proof as far as possible, and that they should propose any further experiments which may be considered necessary for this purpose.

WE learn from the *Electrician* that a prize of 1000 francs (40*l.*) is being offered by the Association des Industriels de France contre les Accidents du Travail, 3, Rue de Lutèce, Paris, for the most efficacious insulating gloves for electrical workmen. They should be strong enough to resist not only the electric pressure, but also accidental perforations by copper wires, &c., and must, in addition, be easy to wear by hands of any size and allow the workmen's fingers sufficient freedom to execute their work. The competition is international, and competitors must send two pairs of gloves, accompanied by an explanatory note, to the president of the Association before December 31, 1900. The Association reserves to itself the right to publish descriptions of samples submitted to it, and inventors should therefore take the precaution of protecting their inventions previously.

A GLANCE through the addresses delivered at the meeting of the British Medical Association held at Ipswich last week, and published in the *British Medical Journal*, shows that leading members of the medical profession recognise the close relationship between medicine and other sciences. The president, Dr. W. A. Elliston, in an address in which he traced the developments of the science of British medicine and the evolution of the modern physician, remarked: "I am not unmindful of the up-to-date requirements of general culture—of an accurate knowledge of anatomy, chemistry, physiology, biology, bacteriology, pathology, physics, optics, mechanics, electricity and photography, which are all essential to the well-educated physician; they are daily called into requisition in order to diagnose and to direct the eye and hand in the treatment of disease." Similar acknowledgment of the dependence of medicine upon other sciences was made by Dr. Pye-Smith in his address abridged in another part of the present number. Mr. Frederick Treves, however, in his address on the progress of surgery during the last hundred years, ended his remarks with a sketch of the surgeon's place in the future, and expressed the hope that surgery might remain a handicraft, and that before all things the surgeon would strive to render his own hands self-sufficing, and not trust too much to diagnoses made for him in the laboratory. Short addresses were delivered by some of the presidents of the thirteen sections of the Association. In the section of pathology, Dr. E. E. Klein spoke upon bacteriology in relation to pathology, giving as illustrations of his theme the bacteriological work bearing upon inflammation, necrosis and cell secretions. Dr. Howard Marsh, in his address to the section of surgery, remarked: "Long a mere matter of routine, the treatment of fractures has lately felt the influence of modern advance in other departments of surgery. The Röntgen process secures an accuracy of diagnosis which formerly was often impossible." Dr. W. G. Smith made some suggestive remarks upon the teaching of pharmacology, pointing out some of the relationships between physiological action and chemical constitution. This fascinating subject has occupied the attention of several physiological chemists, and it offers numerous interesting problems for investigation.

WE learn from the *Athenæum* that the 83rd Annual Meeting of the Swiss Natural Science Society will be held at Thüsis, Canton Grisons, from September 2-4. Three other Swiss scientific societies—the geological, the zoological, and the botanical—will hold their annual meetings at the same time and place. Intending guests are asked to communicate with the president, Dr. Lorenz, at Coire, as soon as possible. Prof. Forel, of Morges, will lecture at the general meeting of the

Society on changes in glaciers; Prof. Zschokke, of Basle, on the fauna of mountain streams; and Prof. Schardt on the tectonic conditions on the northern slopes of the Swiss Alps.

A LENGTHY treatise on that mysterious form of atmospheric discharge known as "globe lightning" appears in the current number of the *Annalen der Physik*. It is by Prof. Max Toepler, the inventor of the Toepler machine and the discoverer of the stratified brush discharge. After comparing all the published records of the phenomenon, he comes to the conclusion that the globe is a form of continuous atmospheric discharge analogous to the "brush arc discharge" of the laboratory. A lightning flash leaves behind it a track of heated and possibly ionised air, along which a slow continuous discharge passes for some time after the flash has passed. When this continuous discharge is strong enough, any part of the track which has an exceptionally high resistance may be made to glow, and the glow may continue for several seconds or even half a minute. The track may be blown aside by the wind or driven by electrostatic forces, and then the globe will be seen to wander as is usually described. It often finishes with another lightning flash, and the thunderclap following that is described as an "explosion" of the ball. Considering the size and duration of the globe, Prof. Toepler estimates its current strength at something between 2 and 20 amperes. Considering that a lightning flash often carries 10,000 amperes, the destruction wrought by globular lightning should be inconsiderable.

THE uses of monochromatic light in optical experiments are so numerous that considerable interest attaches to the paper, on the means of producing such light, by MM. Charles Fabry and A. Pérot in the *Journal de Physique* for July. After pointing out the disadvantages of sodium light on account of the proximity of the D lines, the authors divide the methods of producing a beam of monochromatic light into two, viz.: (1) simplification of a beam of white light, and (2) use of light emitted by a gas. Under the latter method are included (*a*) flames; (*b*) gases or vapours rendered luminous by electricity; (*c*) induction sparks; and (*d*) the electric arc. In connection with (*b*), it is found that the quality of the rays depends on the nature of the current exciting them, and the authors consider the use of (1) a coil with secondary condenser, (2) alternating currents, (3) continuous currents; of these methods the last is the best, though the second is better than the first. While the results of these investigations cannot be briefly summarised, we notice that the authors have shown the possibility of improving the action of Michelson's tubes, of using a modification of the mercury arc of Arons as a source of monochromatic light of great intensity, of using the rays of a certain number of metals for interference observations where the difference of path is considerable, and, by measuring the wave-lengths, of adding a number of new fixed points on the spectrum. The paper concludes with a table of wave-lengths determined by MM. Pérot and Fabry, and compared with the determinations of Michelson.

STORMY and boisterous weather has occurred over the greater part of the British Islands during the past week, and exceptionally heavy rains have been experienced in many districts. On August 3 a storm of unusual severity for the time of year swept across England, and a heavy gale blew over the southern portion of the kingdom, occasioning considerable damage on our coasts, as well as to the fruit and corn in the inland districts. A similar disturbance struck our west coasts on August 6, and although it followed very much the same path as the storm of Friday it was more erratic, both in its track and rate. The storm was heavy again in many parts of England, and further damage to the crops has been occasioned. The temperature has fallen considerably during the last few days, and the weather has been cold for the time of year over the whole country, the mid-day readings in many places being below sixty degrees.

THE new Daily Weather Report, the issue of which was announced in NATURE of July 26 (p. 300), is now on sale every day at the Meteorological Office and several railway bookstalls in London. The attempt thus made to create an intelligent interest in meteorological records and forecasts is one to be encouraged, but we are afraid that the method adopted is not very attractive. The weather charts are admirable, and in connection with the statement of the general situation and the forecasts they are most instructive. Too much prominence could not be given to these two pages of the Report, which ought to find a place in the hall of every educational institution in the country. But the tabular matter included in the Report is of too detailed a character to be of public interest, and the Meteorological Council might usefully consider whether it would not be sufficient to publish such statistical information once a week or once a month instead of every day.

THE high kite flight at Blue Hill Meteorological Observatory, of which mention was made a few weeks ago (p. 252), was, Mr. Lawrence Rotch informs us, exceeded on July 19. A line of six kites reached an altitude of 15,900 feet, or three miles and sixty feet, above the sea, which exceeds the highest point ever reached in America by a balloon used for scientific purposes. Prof. Hazen, of the U.S. Weather Bureau, obtained observations in a balloon at a height of 15,400 feet in an ascent from St. Louis in June 1887. This is the highest ascent in America from which observations have been published. Four and three-quarter miles of steel piano-wire were used at Blue Hill as a flying line. The instruments attached to the kites showed freezing temperature at the highest point and a north-west wind with a velocity of twenty-six miles an hour. The air was found to be exceedingly dry.

THE *Proceedings* of the Geologists' Association for May contains an interesting paper, entitled "The Natural History of Phosphatic Deposits," being an address delivered in February last by the retiring President of the Association, Mr. J. J. H. Teall, F.R.S. The phosphates of igneous rocks and mineral veins are first discussed, and it is pointed out that apatite, the most abundant phosphatic mineral, is the principal source from which the phosphorus of the sedimentary rocks and of organic bodies is derived. Attention is drawn to the points of analogy in the vein-occurrence of apatite and tin-stone. Having shortly described the conditions and causes which bring about the formation of modern phosphatic deposits, the author passes in review the principal occurrences of phosphates in the successive geological formations, and concludes by stating that "from the earliest time down to the present day, the physical and chemical conditions under which phosphatic deposits have been formed have remained essentially the same." A useful bibliography of the subject is appended.

IN the *Bulletin de la Classe des Sciences* of the Brussels Academy (1900, No. 4), M. Louis Dollo, curator of the Brussels Museum, describes the new fish, *Racovitza glacialis*, discovered in the Belgian Antarctic Expedition. This is the third new fish discovered by the party, and only one specimen was found, and that a small one, somewhat mutilated at the caudal extremity, the length of the body, exclusive of the tail, being 82 millimetres. It was found on May 28, 1898, in lat. 71° 23′ S., long. 87° 32′ W., depth 435 metres, and is a member of the family Trachinidæ, distinguished from the genera Bathydraco, Bembrops, Chænichthys, Cryodraco and Gerlachea by well-marked characteristics, which M. Dollo describes. It is, however, most nearly allied to Bathydraco and Gerlachea, and its existence within the Antarctic Circle furnishes a fresh proof of the frequency of the Trachinidæ in the neighbourhood of this circle.

A SUGGESTIVE paper on the driving energy of physico-chemical reaction and its temperature-coefficient is contributed to the *Proceedings* of the American Academy of Arts and Sciences, xxxv. 23, by Prof. Theodore William Richards, in which the author, starting with the close similarity between the equations of Clausius and van 't Hoff, $d\ln P/dT = \lambda/RT^2$ and $d\ln K/dT = U/RT^2$, points out the advantages, previously recognised by Arrhenius, of regarding *pressure* to be the fundamental quantity which determines the progress of chemical reactions, as this aspect affords a more direct method of analysis than the study of volume, concentration or entropy. An expression called the "reaction metatherm" is evolved, which represents in terms of pressure the temperature-coefficient of the equilibrium ratio of ideal physico-chemical reaction. The equation obtained is the mathematical expression of the theorem of Maupertuis or Le Chatelier, and when analysed it shows that the part played by each substance in a reaction may be considered as the logarithm of the product of its "physico-chemical potential" and its actually present pressure. The reaction metatherm may be simplified into a reaction-isobar and a reaction-isochor, according as the pressure or volume is kept constant during the reaction. While, however, the reaction-isobar offers the most convenient basis for calculations to which it is applicable, results under constant volume are more conveniently calculated if the reacting substances are expressed in terms of concentration according to the equation of van 't Hoff.

THE iconography and anthropology of the Irano-Indians is the subject of a recent study by M. Ujfalvy in the current volume of *l'Anthropologie*. He concludes that the ancient Persians had a narrow-faced, dolichocephalic, somewhat flattened head resembling that of the ancient Hindus. They were all fair or reddish, and closely resembled the Macedonians of Alexander. It is impossible to say whether this was the primitive Persian type; at all events, it was their well-characterised type six centuries before our era. Two centuries later the type began to be slightly modified. This took place in the interval between the decline of the dynasty of the Achemenides (328 B.C.) and the rise of that of the Sassanides (240 A.D.). This alteration was probably due to the Semites of Elam and Syria, and to the Turanians of Babylon. The former influence did not affect the dolichocephaly, but it slightly increased the height of the head, and modified the nose considerably. The latter influence shortened the head, and but slightly modified the face. The Sassanide warriors exhibited the new complex type. At the close of the Sassanide period the Arabs reinforced the Semitic characters. M. Ujfalvy accepts and reinforces Houssay's dictum that, in a mixture of Aryans with Mongols or Mongoloids, the latter lose their facial characters, flattening of the nose, prominence of the cheek-bones, absence or sparseness of the beard; but, in exchange, they impose the shape of their skull on the former.

MESSRS. SWIFT AND SON have just patented a very handy little electric lamp for microscopic purposes. The lamp—a 16 candle-power one—is enclosed in a metal cylinder, the inner surface of which is painted white. The light makes its exit through a circular aperture in the side of the cylinder near its free end; the end is closed by a plate set at an angle of 45° and painted white, so as to reflect the light through the circular aperture. The light thus does not pass direct from the incandescent carbon filament to the mirror of the microscope, but is reflected from the white walls of the cylinder. In this way a very even illumination is obtained, which is more uniform than that obtained from the average ground glass lamp. While, however, the light given by this lamp is admirably suited for the ordinary powers such as are attached to the average student's microscope, it is, in our opinion, neither powerful enough nor white enough for high-power work, this being a defect common to all electric microscope lamps. Where in addition a lamp is required for dissection purposes, as is so often the case, the direct light of the ordinary type of electric lamp will be found more suitable. This lamp is very compact and steady, and its movements, especially those about its horizontal axis, are particularly easy and steady.

THE Botanical Museum of Florence has recently received a donation of considerable interest in connection with the history of botany in Italy, viz. the collections made by Micheli, by Bruno Tozzi, and by G. Targioni-Tozzetti in the 18th century, including the type-specimens of species named by these and other eminent botanists. The donation includes also Micheli's and Targioni-Tozzetti's collections of sea-weeds.

IN No. 4 of vol. xxi. of *Notes from the Leyden Museum*, Dr. J. Büttikofer, the director of the Zoological Garden at Rotterdam, records the birds collected by the Dutch expedition to Central Borneo. Testimony is borne to the thoroughness of the work of the English naturalists, the late Messrs. Everett and Whitehead, and Mr. Charles Hose, by the fact that the author has not been able to add a single new species to the avian mountain fauna of the island. Dr. Büttikofer comes to the conclusion that both the mammalian and the avian faunas of Borneo are remarkably homogeneous, especially so far as the lowlands and the mountain bases up to an elevation of about 1000 metres are concerned. In vol. ii. No. 1 of the same serial, Mr. M. C. Piepers defends his theory of the evolution of colour in Lepidoptera, as explained at the recent Zoological Congress at Cambridge, against the criticisms of Miss Newbiggin and Dr. von Linden.

IN *Nature Notes* for August the Selborne Society refers to the urgent need of a crusade against pigeon-shooting.

THE MS. of the second volume of the late Dr. Stark's "Birds of South Africa" has been found amongst the papers of the deceased naturalist, who was killed at Ladysmith during the siege. It has been revised for the press by Mr. W. L. Sclater, director of the South African Museum, Cape Town, and will be shortly published by Mr. R. H. Porter. It will form part of Mr. Sclater's series of volumes on the fauna of South Africa.

THE report of the Zoological Garden of Calcutta for the year 1898–99, which has recently been received in this country, gives a favourable impression of the present condition and prospects of this establishment, drawn up by Lieut.-Colonel P. A. Buckland, the honorary secretary and treasurer. The superintendent of the Calcutta Garden, Babu R. B. Sanyal, who represented that Institution at the International Congress of Zoology at Cambridge in August 1898, contributes to this report an interesting account of his experiences at the Cambridge meeting, and of his observations on many of the zoological gardens of Europe, which he took the opportunity of visiting on the same occasion.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. T. Forsyth Forrest; a Diana Monkey (*Cercopithecus diana*) from West Africa, presented by Mr. W. Cleaver; two Greater Vasa Parrots (*Coracopsis vasa*) from Madagascar, presented by Mr. G. Barfoot; a Silky Cowbird (*Molothrus bonariensis*) from South America, presented by Mr. F. Willes; seven Algerian Skinks (*Eumeces algeriensis*), a Spiny-tailed Mastigure (*Uromastix acanthinurus*) from North Africa, presented by Mr. G. H. Fernan; a Common Viper (*Viper berus*), British, presented by Mr. Alfred Cooper; a Green Lizard (*Lacerta viridis*), a Dohl's Snake (*Zamenis dahli*), European; two Snakes (*Coluber prasinus*) from Upper Burmah, deposited; two Ring-necked Pheasants (*Phasianus torquatus*), two Gold Pheasants (*Thaumalea picta*) from China, a Pheasant (*Phasianus colchicus*), five Barn Owls (*Strix flammea*), British, purchased; a Japanese Deer (*Cervus sika*), born in the Gardens.

## OUR ASTRONOMICAL COLUMN.

COMET BORRELLY-BROOKS (1900 *b*).—Several observations of this comet are announced. The comet is at present easily seen with a small telescope, but is becoming fainter.

*Ephemeris for* 12*h. Berlin Mean Time.*

| 1900. | | R.A. h. m. s. | | Decl. ° ′ | | Br. |
|---|---|---|---|---|---|---|
| Aug. 9 | ... | 3 11 45 | ... | +61 11·9 | ... | 0·91 |

| 16 | ... | 3 50 8 | ... | +75 55·7 | ... | 0·63 |

During the week the comet passes rapidly northwards from α Persei, across into Camelopardus, and then near the boundary of this constellation and Cassiopeia. Its path is at present so nearly linear that it may be found by sweeping along the direction formed by the stars π, κ and α Persei.

EPHEMERIS OF COMET 1894 IV. (SWIFT).—Mr. F. H. Seares sends the following search ephemeris for the assistance of interested observers:—

*Ephemeris for* 12*h. Berlin Mean Time.*

VARIABLE STARS IN CLUSTERS.—*Harvard College Observatory Circular* (No. 52) contains the results of the measures of a set of photographs of the star cluster Messier 3 (N.G.C., 5272). This object is so low in the sky at Arequipa, and the stars so faint, that satisfactory photographs of it could not be obtained with the 13-inch Boyden refractor with exposures less than 90m. The rate of increase of the light of many of these stars is extremely rapid, and in order to determine such change with the greatest precision, it is necessary to have photographs taken with short exposures. Accordingly, at Prof. E. C. Pickering's request, Prof. J. E. Keeler has taken a series of excellent pictures of the cluster with the 3-foot Crossley reflector of the Lick Observatory. The first of these had an exposure of 60m., while twenty-four others were obtained with exposures of 10m. each. Prof. Bailey has examined these photographs very carefully, devoting attention specially to three of the variable stars. It has previously been stated (*Circular* No. 33) that the proportion of variable stars is greater in this cluster than in any other object of the same class.

The periods of the three variables were found to be: No. 11, 12h. 12m. 25s.; No. 96, 12h. 0m. 15s.; No. 119, 12h. 24m. 31s. The variations were recorded for intervals of 5m., and are given in a table. From this it appears that the total increase of light takes place in the case of No. 11, within 70m.; No. 96, within 60m.; and No. 119, within 80m. The greatest rapidity of increase of light occurs in the star No. 96, which increases during 5m. at the rate of at least 2·5 magnitudes per hour, and during 30m. at the rate of more than 2·0 magnitudes per hour. This rate of change appears to be the most rapid of any known variable. The Algol variable U Cephei, which perhaps undergoes the most rapid change of any variable *not* found in clusters, changes at the rate of about 1·5 magnitudes per hour during about 30m. of its period. In all these stars the rate of change is relatively slow near the beginning and end of the period of increase. In No. 96 the increase is about *ten* times as rapid as the decrease. Generally speaking, the lengths of period and form of light curves of these three stars are similar to those of the variables in the clusters Messier 5 and ω Centauri (*Astrophysical Journal*, vol. x. p. 255).

## RECENT INVESTIGATIONS ON RUST OF WHEAT.

RUST, or mildew, is familiar to the agriculturist as a disease destructive to wheat and other cereals, and to the botanist as the subject of important researches relating to fungi. It was known in times of antiquity, as shown by numerous references indicating its destructiveness. Virgil says, "Soon, too, the corn gat sorrow's increase, that an evil blight ate up the stalks" ("Georgics," i. 150-1). In Britain, it is stated that "mildew of wheat-plants has been known for over 300 years, according to the records" ("Report on Mildew on Wheat Plants, 1892," Board of Agriculture, 1893, p. 25). Shakespeare ascribes it to "the foul fiend Flibbergibbet" (*King Lear*, Act iii. Scene 4). The works on husbandry of Hartlib (1655) and Jethro Tull (1731) refer to it. The connection of rust of cereals with a specific fungus is generally ascribed to Fontana (1767), and Persoon, after further investigation, in 1797 named the fungus *Puccinia graminis*. An account of rust, with illustrations of the *Puccinia*, by Sir J. Banks in 1805, is apparently the first important paper on the rust and its fungus in Britain. Since then the epidemic has been the subject of many papers, and of, at least, three organised inquiries. The historical side of the subject is conveniently summarised by Worthington G. Smith ("Diseases of Crops," London, 1884, Chapter xxv.), by C. B. Plowright ("British Uredineæ and Ustilagineæ," London, 1889, p. 46), and in the Board of Agriculture report ("Report on Mildew on Wheat Plants, 1892," Board of Agriculture, 1893, p. 25).

Rust of wheat occurs throughout Britain, especially in the wheat-growing districts, and forms of it are found on oat, barley, rye, and almost all grasses The losses from the form on wheat, reported to the Board of Agriculture in 1892, vary from nine to sixteen bushels per acre of crop. Rust-epidemics have been the subject of special attention in Europe, more particularly in Sweden, Germany, France and Austria. A rust conference was formed in 1890 for Australasia, and still continues to meet. In the United States of America, the Department of Agriculture sanctions the statement that "the damage to wheat and oats from rust in this country probably exceeds that caused by any other fungous or insect pest, and in some localities is greater than that caused by all other enemies combined" (Carleton, M. A., "Cereal Rusts of the United States," U.S. Department of Agriculture, *Bulletin* 16, 1899). In India and Japan, substantial losses are ascribed to this disease.

The remedy for this epidemic is a difficult problem, and the aim of recent research has been, in the first place, to obtain a true conception of the fungus causing it. The facts leading up to recent investigations may be briefly reviewed. It is an old and deep-rooted belief amongst growers of wheat that the rust of their crops is influenced by the neighbourhood of barberry bushes. Evidence of this is seen in certain old enactments enforcing destruction of the barberry; for instance, that passed by a parliament at Rouen in 1660, and others included in the Province Law of Massachusetts (America) between 1738 and 1761. Sir Joseph Banks, in his paper (1805), holds the same opinion.

In 1841 Prof. J. S. Henslow (*Journal* of the Royal Agricultural Society, vol. ii. 1841) suggested that the yellow summer rust of wheat, and the black mildew which comes later, are stages in the life of one and the same fungus. Passing over many papers discussing these relationships, we come to one by De Bary published in 1865 ("Untersuchungen üb. Uredineæ." *Monatsber. d. Berlin Akad.*, 1865). From his experiments De Bary concludes, that the yellow summer rust (*Uredo linearis*, Persoon) on *Gramineae*, the black autumn rust (*Puccinia graminis*, Persoon) also on *Gramineae*, and the rust on barberry (*Aecidium berberidis*, Persoon) with its associated "spermogonia" stage, are phases in the life-history of the same fungus, for which the name *Puccinia graminis* is retained. In other words, that three (or four) recognised species of fungi are one and the same. At the same time a new phenomenon in the life of fungi was revealed, namely, that there existed parasitic fungi which required two host-plants in order to develop the forms of reproduction included in their life-cycle; this De Bary named metœcism or (as better known in Britain) heterœcism. The life-history of *Puccinia graminis*, as defined by De Bary, is given in all our text-books. Uredospores (see Fig. 1) are produced on wheat and other *Gramineae* throughout the summer, and infect the same group of host-plants; the teleutospores of the *Puccinia* stage hibernate and in the following spring germinate, producing secondary spores (also known as sporidia), which infect barberry foliage and give rise there to the *Aecidium* stage with its aecidiospores; aecidiospores do not infect barberry again, but on *Gramineae* produce the uredospore stage, thus completing the cycle. Accompanying the aecidium-cups there occurs constantly a form of reproduction. the spermogonia, which gives off spermatia or spore-bodies whose function neither De Bary, nor any one since, has been able to determine.

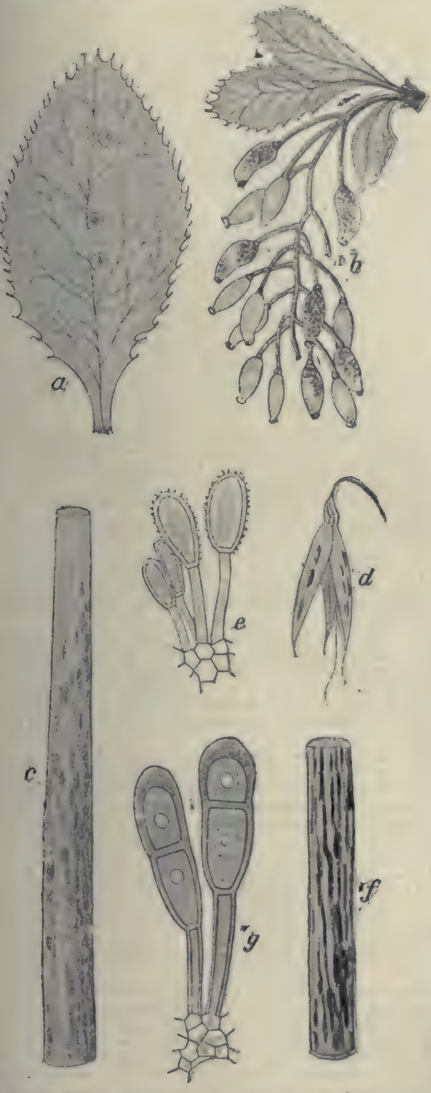

FIG. 1.—Black rust of oats (*Puccinia graminis*, spec. form *Avenae*). *a*, leaf, and *b*, cluster of fruits of barberry with *Aecidium berberidis* (nat. size); *c*, leaf, and *d*, a spikelet of oat with *Uredo* stage (nat. size); *e*, uredospores (× 500); *f*, sheath of oat with *Puccinia* stage (nat. size); *g*, teleutospores (× 500). (J. Eriksson.)

These results had an important and direct bearing on rust-epidemics of cereals, and they gave an impetus to further research on the biology of the whole group of rust-fungi or *Uredineae*, and, in fact, of all other parasitic fungi. In 1889, twenty-five years after De Bary's first results, both Plowright (*loc. cit.*, p. 56) and Rostrup published a list of fifty heterœcious rust-fungi. Recently, Dietel (Engler's "Pflanzenfamilien") gave about a hundred cases, including species outside the *Uredineae*. Works like Plowright's "British Uredineæ" are the evidence of this impulse, and a perusal of current botanical periodicals shows that the subject is by no means exhausted.

Ten years ago, three species of rusts occurring on crops of cereals were recognised:

(1) *Puccinia graminis*, with its *Aecidium* stage on barberry and mahonia; its uredospore and teleutospore stages on wheat, barley, oats, rye, and about a hundred species of grasses (see Fig. 1).

(2) *Puccinia rubigo-vera*, with *Aecidium* on many species of *Boragineae*; uredospores and teleutospores on wheat, rye, and a number of grasses (see Fig. 2). A variety, *simplex*, was distinguished on barley.

(3) *Puccinia coronata*, with *Aecidium* on species of buckthorn (*Rhamnus*); uredospores and teleutospores on oats and several grasses.

The four important European cereal-crops were thus known to have each two forms of rust-fungi, distinguished in their external characters, and with distinct *Aecidium* host-plants. Yet it was by no means certain that epidemics of rust were fully traced out. Fortunately the economic importance of rust-epidemics was enough to enforce attention from State departments, notably in Sweden, United States of America, Australasia, and in various parts of Europe and other countries. In Britain, while good work has been and is still done on rust-fungi, there has, in recent times, been no specially organised research relating to cereal rusts, probably because recent developments on the subject have rendered a research too extensive for the resources of any but workers specially retained and remunerated. The investigations on rusts of cereals reviewed here are mainly the outcome of State-aided research.

In Sweden, the Government in 1890 offered ten thousand kröner (about 560*l.*) to the Royal Swedish Academy of Agriculture for an investigation on rust of wheat, &c., intended, at first, to extend over three years, but which has been continued up till now. The grant was placed under the control of Jakob Eriksson, now professor of vegetable physiology at the experimental station of Albano, near Stockholm. The experiments were started in 1890; the first important results of Eriksson and his co-worker, E. Henning, appeared in 1894 (*Zeitsch. f. Pflanzenkrankheiten*, iv. 1894, pp. 66, &c.), and as a bulky volume in 1896 ("Die Getreiderost," Stockholm, 1896; 463 pp. and 14 plates). Other contributions, and re-statements of former work, have been made by Eriksson in almost every existing botanical periodical. The present summary is based chiefly on the latest re-statement (*Revue gén. d. Sciences*, ii. January 15, 1900, pp. 30–39), with aid from other papers.[1]

In Eriksson's experiments test-plants of cereals were grown from seed, or young plants from the open were transferred into pots. The soil used was generally sterilised. After inoculation with rust the plants were watered with distilled water, placed under large glass bell-jars moistened with distilled water, and left undisturbed for twenty-four hours in glass-houses specially constructed for the experiments. After this, observations were made at frequent intervals. The main lines of investigation were: (1) to define the species which cause rusts of cereals and grasses, and to trace their life-history; (2) the propagation of the rusts; (3) germination and vitality of the various forms of spores.

According to Eriksson's results, the three species and one variety of rusts attacking cereals and grasses as recognised in 1890 really represent twelve species and many subdivisions. His list is as follows, but the less important host-plants amongst the grasses are omitted:—

Species 1. *Puccinia graminis*. Pers. (Black Rust), with *Aecidium berberidis*. Specialised form (1) *Secalis*, on *Secale cereale* (Rye), *Hordeum vulgare* (Barley), *H. jubatum*, *Triticum repens*, *T. caninum*, &c., *Elymus arenarius*, and *Bromus secalinus*. (2) *Avenae*, on *Avena sativa* (Oat), *A. elatior*, &c., *Dactylis*

---

[1] J. Eriksson: *Ber. d. deutsch. botan. Gess.*, 1894, p. 292; 1897, p. 183. *Jahrbuch f. wiss. Botanik*, xxix. 1896. *Botan. Centralblatt*, lxxii. 1897, pp. 321–5 and 354–62. *Centralblatt f. Bakter. u. Parasitenkunde*, Abt. ii. 1897, pp. 291–308.

*glomerata*, *Alopecurus pratensis*, &c. (see Fig. 1). (3) *Tritici*, on *Triticum vulgare* (Wheat). (4) *Airae*, on *Aira caespitosa*. (5) *Agrostis*, on *Agrostis stolonifera*, &c. (6) *Poae*, on *Poa compressa* and *P. caesia*.

2. *Pucc. Phlei-pratensis*, Er. et Hen., *Aecidium* unknown. On *Phleum pratense* and *Festuca elatior*.

3. *Pucc. glumarum* (Schm.), Er et Hen. (Yellow Rust), *Aecidium* unknown. Sp. form (1) *Tritici*, on Wheat (see Fig. 2). (2) *Secalis*, on Rye. (3) *Hordei*, on Barley. (4) *Elymi*, on *Elymus arenarius*. (5) *Agropyri*, on *Triticum repens*.

4. *Pucc. dispera*, Er. (Brown Rust of Rye), with *Aecidium Anchusae*. On Rye.

5. *Pucc. triticina*, Er. (Brown Rust of Wheat), *Aecidium* unknown. On Wheats—*Triticum vulgare*, *compactum*, *spelta*, and *dicoccum*.

6. *Pucc. bromina*, Er., *Aecidium* unknown. On many species of *Bromus*.

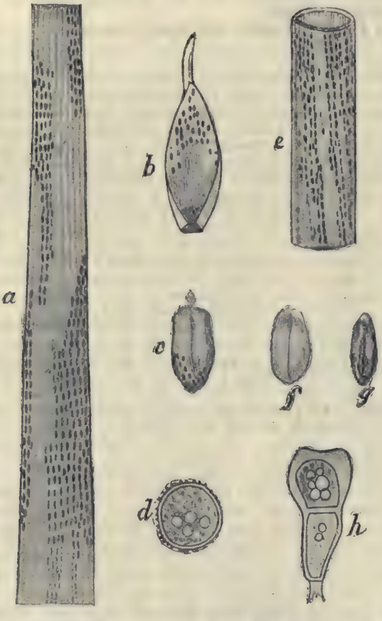

FIG 2.—Yellow rust of wheat (*Puccinia glumarum*, spec. form *Tritici*): *a*, leaf (nat. size), *b*, outer glume (× 2), and *c*, a grain (× 2), bearing the *Uredo* stage; *d*, uredospore (× 375); *e*, sheath bearing *Puccinia* stage (× 2); *f*, a healthy grain, and *g*, a rusted grain (both × 2); *h*, teleutospore (× 500). (J. Eriksson )

7. *Pucc. agropyrina*, Er., *Aecidium* unknown. On *Triticum repens*.

8. *Pucc. holcina*, Er., *Aecidium* unknown. On *Holcus lanatus*, and *H. mollis*.

9. *Pucc. Triseti*, Er., *Aecidium* unknown. On *Trisetum flavescens*.

10. *Pucc. simplex* (Kleb.), Er. et Hen., *Aecidium* unknown. On Barley.

11. *Pucc. coronifera*, Kleb., with *Aecidium Catharticae*. Sp. form (1) *Avenae*, on Oat. (2) *Alopecuri*, on *Alopecurus pratensis*, &c. (3) *Festucae*, on *Festuca elatior*. (4) *Lolii*, on *Lolium perenne*. (5) *Glyceriae*, on *Glyceria aquatica*. (6) *Holci*, on *Holcus lanatus* and *H. mollis*.

12. *Pucc. coronata* (Corda), Kleb. (Crown Rust), with *Aecidium Frangulae*. Sp. form (1) *Calamagrostis*, on *Calamagrostis arundinacea*, &c. (2) *Phalaridis*, on *Phalaris arundinacea*. (3) *Agrostis*, on *Agrostis stolonifera*, &c. (4) *Agropyri*, on *Triticum repens*. (5) *Holci*, on *Holcus lanatus* and *H. mollis*.

Comparing these species with those known in 1890, *Puccinia graminis* is now divided into Eriksson's 1 and 2; *Puccinia rubigo-vera* into species 3 to 9: the variety *simplex* is now the species 10; and *Puccinia coronata* is divided into 11 and 12.

The species are distinguished by characters of uredospore and teleutospore, and by the host-plants of the *Aecidium*, where known. A species may be subdivided into "specialised forms," which agree in all external characters with the species, but form (1) is tied to one or more species of host, and its uredospores will not infect the hosts of forms (2), (3), &c. Thus *Puccinia graminis* has a specialised form confined to wheat, one to oat, and a third which attacks both rye and barley. The occurrence of the *Aecidium* on the same host, *e.g.* that of *Puccinia graminis* on barberry, might seem to afford a stepping-stone between specialised forms; yet Eriksson says definitely that, for example, in the form *Avenae* "the form of *Aecidium* on barberry which gives black rust on oat can infect oat only." It may be mentioned that specialised forms are not peculiar to the rusts of *Gramineae*. Klebahn in a recent paper (H. Klebahn, "Ueber den gegenwärtigen Stand der Biologie der Rostpilze," *Botan. Zeitung*, 1898, pp. 145-58) gives a list of heterœcious fungi, which show subdivision into "biological species" or "species sorores," forms identical with or only slightly different from those indicated by Eriksson's term of specialised forms. Klebahn has also an interesting discussion on the nature of these forms of parasitic fungi, and joins issue with many of Eriksson's results.

Carleton (*loc. cit.*) carried out a long series of experiments for the United States Department of Agriculture. The procedure was almost identical with that of Eriksson, and the results generally support the Swedish observations. Carleton distinguishes the following species and forms on cereals:—

Orange leaf rust of wheat, *Puccinia rubigo-vera tritici*; identical, or almost so, with Eriksson's *Puccinia triticina*.

Orange leaf rust of rye, *P. rubigo-vera secalis*; either Eriksson's *P. glumarum secalis* or *P. dispersa*.

Crown rust of oats, *P. coronata*, Corda; Eriksson's *P. coronifera*, Kleb.

Black stem rust of wheat and barley; *P. graminis tritici*, Er. et Hen.
,, ,, ,, rye, *P. graminis secalis*, Er. et Hen.
,, ,, ,, oats, *P. graminis avenae*, Er. et Hen.

The American results differ from the Swedish in two important points:—

(1) Whereas *Puccinia glumarum tritici* is the most destructive rust throughout Europe, it does not seem to occur in America, where the common rust on wheat is *Puccinia rubigo-vera tritici*.

(2) The specialised form *Puccinia graminis tritici* in America appears to infect, not only wheat, but also barley; this is not the case in Sweden.

These differences indicate that the rust of wheat or other cereal in one country may not be the same as that in another; and that specialised forms are variable. Eriksson distinguishes degrees of specialisation and classifies the forms thus: (1*a*) Forms restricted to one species of host, or to several species of a genus, *e.g.* species 4, 8, and 1 (5) in the above list. (1*b*) Forms occurring on hosts belonging to different genera, *e.g.* species 1 (1) and 1 (2) in list.

(2) Forms, which, under certain conditions of environment, are less fixed in regard to their hosts; thus, until recently, Eriksson included species 4, 5, 6, 7 as forms of one species, *Puccinia dispersa*, and it is still doubtful whether they are distinct enough in their external characters to be regarded as species

Further experiments are necessary to clear up many points regarding the distribution of species of rust. Yet the practical bearing of the results is evident. For example, wheat cannot now be regarded as subject to infection from any cereal or grass showing rust, but only from those which are host-plants of the species or specialised forms peculiar to wheat; thus a comparison from the above lists shows that no rust from oats has been found to infect wheat. The theoretical bearing of biological species or forms in relation to the classification and phylogeny of fungi is also of the deepest interest.

The propagation of the rusts of cereals has, in the hands of recent investigators, assumed new aspects. The life-cycle of *Puccinia graminis* as defined by De Bary, and already given above, is the one generally described in text-books. Many observers, however, have doubted whether this, the perfect life-history, is always followed entirely. Strong objections of this kind are given by Worthington G. Smith (*loc. cit.*), although at the time (1884) these were raised, the imperfect knowledge regarding the species of rust-fungi somewhat weakens the arguments at the present time. Yet Eriksson, Carleton, and other recent workers show even greater opposition. We are told that rust is a serious epidemic amongst wheat in Australia where there are no native barberries; in India an undoubted black rust (*Puccinia graminis*) occurs on wheat where there are no barberries nearer than 300 miles off in the Himalayas. More conclusive is Eriksson's observation of aecidium-cups on a barberry, yet the rust could only be traced on rye, barley, and couch-grass to a distance from 10 to 25 metres; or, again, tufts of *Festuca elatior* were found with uredospores of *Puccinia coronifera*, while across a road there was a hedge of *Rhamnus* almost free from the aecidial stage, yet easily infected by means of teleutospores from the grass transferred to it by hand. These observations appear to show, firstly, that the aecidial stage is not necessary in the life-history of rust of cereals; secondly, that the range of infection by aecidiospores, or the reverse, is not great. What then remains is one of the following possibilities: (1) The mycelium can hibernate and resume activity in the following spring; (2) the fungus is carried over to a new season by the seed-grain, either through adherent spores, or in some form internally; (3) the uredospores can hibernate; (4) the teleutospores can infect other *Gramineae*. In reviewing these we can only give a few of the leading points relating to cereals.

It is unlikely that the mycelium hibernates in the dead remains of grasses, because it must then be capable of living as a saprophyte for a short time in spring when it awakens to activity; this has not yet been proved. If, however, one examines the undergrowth of an area of grass in winter, green shoots are generally present; the mycelium may winter here. Yet grain-crops are never sown except on ploughed land, and there is no good evidence to show that epidemics of rust, extending over whole acres, are propagated altogether from patches of wild grass. Uredospores adhere to the grain of rusted cereals, and there is a fair amount of evidence to show that these may assist the fungus through the winter. In the United States, Carleton believes that the uredospores of the orange leaf rust of wheat and rye are produced and can germinate late in the autumn, and so infect the sprouted autumn-sown crop for next year. Eriksson, on the other hand, has failed to discover that any one of the rusts of wheat lives all round the year in the *Uredo* stage in Sweden, although Sorauer states that in Germany the *Uredo* mycelium of *Puccinia rubigo-vera* hibernates without injury. There is thus a possibility that the uredospore stage may transmit a rust from year to year. This is more probable if the climate be suited to prolong the growth of grasses late into autumn or early winter, and if the specialised form of rust has more than one host-plant; if it occurs only on one cereal, it seems improbable that enough stray plants are present after harvest to account for a widespread reappearance of rust in the succeeding year. Whether uredospores adhering to straw or grain can survive the winter and germinate has not yet been made quite clear. In laboratory experiments it has been observed that uredospores frequently exhibit deferred germination. After being soaked in water, only a small percentage may produce germ-tubes. Eriksson and others have observed that if the dormant spores are cooled in ice, a further proportion are induced to germinate. Klebahn states that the greater number of all forms of spore germinate if placed on a suitable host-plant; he believes that the proportion which do not germinate at once, do so gradually later on, and sees in this an adaptation for preservation of the race.

The teleutospores of the rusts of cereals have, as a rule, proved incapable of infecting cereals or grases, the aecidium stage must intervene. There is, however, the objection that observations can only be made under more or less artificial conditions in laboratory or green-house, and may not fulfil all the conditions of infection out-of-doors. Plowright recorded an instance of infection of cereals from the teleutospores of *Puccinia graminis* (*Gardeners' Chronicle*, August 19, 1882), but gives no special prominence to it in his "British Uredineæ" (1889). Indirectly certain facts lead one to suppose that teleutospores may have the power to reproduce other stages in the life-history than the aecidium. A rust-fungus of the group *Leptopuccinia* (e.g. *Puccinia malvacearum* on mallow and hollyhock) produces only teleutospores; these give rise to sporidia, which re-infect the mallow, and form the mycelium from which a new crop of teleutospores arises. Many forms of rust-fungi have only teleutospores and uredospores on the same host: for instance, in Eriksson's list many of the forms have no *Aecidium*; either the hosts of this stage remain to be discovered, or the teleutospore production is fruitless, or the teleutospores are capable of bringing about infection of the cereal or grass host. Species like *Puccinia suaveolens* on thistles have all the forms of spore on one host-plant except aecidiospores, which are unknown; here the teleutospores must, after hibernation, bring about re-infection of the host. The existence of rust-fungi producing all the forms of spore on one host, shows that two hosts are not necessary for the development of the aecidium stage, and suggests that heterœcism may be a later development in the history of the group. It is also noteworthy that the teleutospore is produced by all rust-fungi, with very few exceptions. It is therefore not improbable that the teleutospores of heterœcious rust-fungi may still, through their sporidia, retain the power of infecting the host on which they are produced; in other words, that heterœcism may be facultative.

In investigating the germinative power of teleutospores, Eriksson finds the general opinion, that teleutospores must hibernate, to be true only to a certain degree. As a rule, they do not germinate unless they have passed the winter exposed to all the changes of weather out-of-doors. Spores collected in autumn and kept indoors soon lose the power of germination; hence his conclusion that rusted straw housed in barns will not be in a condition to propagate the disease next spring. In the case of spores left out-of-doors, the germinative power decreases rapidly during the year after their formation, and in October they no longer germinate. There is one exception, teleutospores of *Puccinia graminis tritici* have a feeble power of germination after two winters. On the other hand, Eriksson finds that certain teleutospores (e.g. *Puccinia dispersa* and *P. glumarum tritici*) can germinate in the year of their formation; in the case of the former species, aecidia were produced on *Anchusa* in a short time; in the latter form the host of the aecidia is unknown. Plowright states that a bundle of rusted wheat straw laid near plants of *Anchusa* in August 1885 produced aecidia in September.

Eriksson, after all his experiments, professes to be at a loss to account for epidemics of rust on cereals year after year by external contagion alone, and he adopts the view that *infection is due to an internal germ*. He thus introduces an agent for the propagation of parasitic fungi which has hitherto been received very sceptically by the plant-pathologist. His conclusion is the result both of experiment and examination with the microscope. In the experiments, varieties of cereals were used which are known to be specially liable to rust. Vigorous shoots were taken out-of-doors in spring, and enclosed in long glass tubes with the open ends closed with cotton wool. Seeds were also germinated in sterilised soil and kept in culture boxes, with precautions against entrance of spores by stuffing the ventilators with cotton wool. At first the results were negative, but after (in some way) improving the methods, the test-plants showed rust, especially those shoots taken from out-of-doors. Examination with the microscope failed to reveal any mycelium or other traces of the fungus until a few days before appearance of the rust externally. At this time, however, with the aid of staining reagents, certain protoplasmic bodies were observed in the green cells near the margin of a rust-patch. These plastids occur solitary or in masses in a cell; they are oblong or slightly curved, simple or somewhat branched, and recall the form of bacteroids found in root-tubercles of the *Leguminosae*. In a short time the branch-processes pierce the cell-wall of the host, and develop outside the cell into an intercellular mycelium, part of the original plastid remaining inside the cell as the first haustorium or sucker. Soon after this a rust-pustule appears on the exterior of the host. The plastid is regarded as having passed a period mingled with the cytoplasm of the host "in a kind of symbiosis," till in response to external conditions—nutrition, moisture, heat and light—the "mycoplasm" becomes separated from the cytoplasm, and assumes the form of a plastid. The mycoplasm has its origin from the rust-fungus in the parent host-plant, it becomes located in the embryo of the grain, develops apace with the young plant, and so bridges the period between one crop and the next. The following general facts are said to support this mycoplasm theory: (1) The appearance of rust on plants carefully isolated from contagion; (2) the disease in a field appears regularly four to five weeks after sowing the grain of certain varieties of wheat and barley known to be very liable to yellow rust; (3) this rust is always more prevalent in sunny parts of the field.

A hypothesis so revolutionary is not likely to be adopted by a cautious fungologist without further evidence. At present, as far as we know, no figures illustrating the development of the mycelium have been published, nor can we obtain details of the staining methods adopted. Klebahn (*loc. cit.*) has entered his protest to the theory, chiefly, however, in general terms. In regard to the prevalence of rust in sunny parts of a field, he points out that Eriksson's own results confirm the fact that dormant spores are induced to germinate by alternate cooling and heating, drought and moisture; just the conditions to be expected in early summer in sunny parts rather than in shaded parts of a field. Klebahn also supports the view that spores of rusts are capable of wider distribution than Eriksson's results show; for instance, they have been found in analyses of air. We may recall, in support of this, Robert Hartig's observation in the Tyrol, when, after showers of rain, a yellow dust, coating objects in the neighbourhood, was found to consist almost entirely of the yellow spores of a rust-fungus, *Chrysomyxa* ("Diseases of Plants," Tubeuf and Smith, London, 1897, p. 54). If it be the case, as Eriksson says, that certain rusts of cereals appear regularly in four or five weeks, it seems quite as likely to indicate external infection of young plants at a certain stage in their existence, as to support the theory of an internal germ. The Swedish experiments in isolating test-plants from contagion have been repeated in America by Bolley.[1] Young plants of cereals growing amongst others in a field were enclosed in rust-proof cases; they grew to maturity without showing any rust, although plants left unenclosed were much attacked. The results are quite negative.

Recent investigations have been directed towards advancing our knowledge regarding the varieties of cereals suited to resist the various forms of rust. Carleton,[2] whose work was aimed in this direction, summarises our general knowledge thus: "as yet there is but little certainty concerning rust resistance, which varies continually under different conditions. Heretofore, in testing varieties for rust resistance, little attention has been paid to the species of rust concerned." For our own part, we feel that our ability in combating the diseases of plants would be greatly strengthened by searching investigations towards attaining disease-proof varieties. A certain amount has been done, much more must yet be done. The results hold good for only small areas of the earth, and there must be thorough and systematic research in many countries before any definite conclusion be arrived at. From a practical point of view the combating of rusts of cereals, and diseases of plants generally, seems likely to be solved sooner in this way than by investigations on the complex conditions of life amongst the rust-fungi. One cannot but feel that the long recent researches have added to what we knew only minor details of practical importance, although they have opened new vistas of the deepest interest to the fungologist; the outstanding lesson is the close dependence of the fungi on their environment, and the complexity thereby introduced into the study of diseases of plants.

WILLIAM G. SMITH.

## *MEDICINE AS A SCIENCE AND MEDICINE AS AN ART.*[3]

IT has sometimes been disputed whether medicine should be regarded as a science or an art, but there is no doubt that the original meaning of the term medicine, in English and in other languages, is the Art of Healing. Medicine is so defined by Aristotle, and it has all the characters of an art. It depends upon experience and skill; it deals with individual cases; and the perfection it aims at is practical, not speculative: the knowledge how to do, not the knowledge how things happen.

Nevertheless, as practical navigation is founded on astronomy, meteorology and physics; as the art of agriculture rests on botany, geology and vegetable physiology, so the art of medicine depends on the science of pathology, the practice of physic on the principles of physic.

On the one hand, then, we must never forget that we practice an art; we must never allow theories, or even what appears to be logical deduction, or explanations, however ingenious, or statistics, however apparently conclusive, or authority, however venerable, to take the place of the one touchstone of practical medicine, observation and experience. We must never treat the disease without considering the patient, for the art of healing is the art of healing individually; nor need we wonder if profound learning and the best scientific training sometimes fail to make a successful practitioner. For beside adequate knowledge to save us from gross blunders, and a strenuous endeavour to do your best for each individual patient, however uninteresting the case or however irksome and unrewarded our toil—beside these first requisites for our art, there is ample room for those personal qualities which ensure success in every department of life; for power of observation and insight, for the personal influence by which a strong character will secure obedience and inspire hope, for the judgment which divines what kind of remedies are suited to each patient, what kind and of what strength, and for the sympathy which puts one in the patient's place, and not only meets, but anticipates his wants.

On the other hand, however, if medical science without art is inefficient, medical art without science is not only unprogressive, but almost inevitably becomes quackery. As soon as we treat our patients by rule of thumb, by tradition, by dogmas, or by metaphysical axioms, we do injury to ourselves as well as to them. The bone-setter who is ignorant of anatomy; the wise woman, who cures by charm, are not more irrational or less successful than was the physician of the seventeenth century who, in obedience to the doctrine of signatures, advised an infusion of roses for hæmorrhage, and saffron for jaundice, and lung-wort for consumption; or the astrologer who prescribed salts of silver, of iron, copper, lead, or mercury in accordance with the horoscope of the patient and the planet under which he was born.[1] Not less mischievous, and in the true sense of the word unscientific, were the systems of medicine known as the Iatromechanical and the Iatrochemical, which in their turn had their vogue. The Brunonian system, explaining all diseases as due to laxity of fibre, was no better; for indiscriminate use of "corroborants," or as they would now be called "tonics," is irrational. There is no such thing as a tonic or strengthening medicine, the only source of strength is oxidisable food, and bitter medicines only give strength indirectly by improving appetite. The last of the systems of medicine founded on a dogma is homœopathy, of which the theoretical absurdity is somewhat concealed by the more obvious nonsense of infinitesimal doses. It, like the other systems which preceded it, is not a rival to rational medicine; they are not mistaken answers to a legitimate question, but attempted solutions of a problem which does not exist, attempted answers to a riddle which has none.

Apart from these exploded systems of treatment, our profession has often suffered from lack of the scientific, inquiring, sceptical spirit, and has often been led too easily by authority, by tradition, and by fashion. The reckless abuse of venesection in the last century and the former half of this led to almost complete disuse of a valuable means of treatment; the misuse of mercury in the treatment of syphilis led to the denial of its unquestionable efficacy; have we not seen the value of stimulants with fever lead to their indiscriminate use in almost every ailment? Has not the immense value of careful and thorough nursing led to its absurd exaltation to an independent place, as if good nursing was anything more than an intelligent carrying out of the physician's directions? Has not the remarkable powers of electrical stimuli led to a blind, unscientific and mischievous employment of this remedy, as if it had some mystic power apart from its demonstrable physiological effects? May we not say the same of hydropathy, of massage and of hypnotism? It is significant that the irrational exaltation of any of these particular modes of treatment into a panacea, while it begins in want of scientific intelligence invariably ends in imposture and deceit. Our only safeguard against the spirit of quackery and the deserved loss of public confidence in the

| ☉ | ☽ | ♂ | ☿ | ♃ | ♀ | ♄ |
|---|---|---|---|---|---|---|
| Sol | Luna | Mars | Mecurius | Jupiter | Venus | Saturnus |
| Au | Ag | Fe | Hg | Sn | Cu | Pb |
| Sunday | Mon-day | Mardi | Mercredi | Thors-day | Vendredi | Saturday |

These relations of metals to the planets, and also to the days of the week, are commemorated in the phrases:—*lunar* caustic, *martial* disposition, *mercurial* temperament, ℞ before a prescription, *Cuprum a Cypro* (*divapoteus Cypri*) and *saturnim* gout.

profession which it brings with it, is continued recurrence to the scientific basis on which the practice of medicine rests. Our art is most satisfactory and efficient when most closely resting on science. The surgeon is continually guided by anatomy and mechanics in dealing with injuries and deformities. The physician is often able to apply his knowledge of chemistry and natural history to the direct and satisfactory treatment of disease. In general, medical science justifies its claim to the title by the same conclusive argument as astronomy or chemistry—by its predictions coming true. In particular, the detection and treatment of plumbism, the diagnosis and cure of scabies and ringworm, the treatment of poisons by chemical antidotes, and of specific diseases by attenuated inoculations are all instances of strictly scientific medicine. Nor can I refrain from citing the most recent and one of the most remarkable advances of our science in the discovery of the origin of malaria. This heavy tax upon national as well as individual vigour and happiness has been known and treated from the dawn of medicine; but although by a happy accident its efficient treatment was discovered, it is only lately that, by the combined labours of scientific physicians—Frenchmen, Italians, and our own countrymen—the origin of the disease has been discovered, the mode of its transmission traced, the diagnosis of its several forms established, and its prevention brought within reasonable hope.

We know that treatment of symptoms without a diagnosis is always unsatisfactory, and frequently worse; but we know also that diagnosis must rest upon accurate knowledge of morbid anatomy, and of the natural history of the disease. Scientific medicine based on observation and experiment is always practical as well; but empirical medicine, whether based upon fanciful speculation or working by blind rule of thumb, is the most unpractical thing that can be.

*Preventive Medicine and Aetiology.*—That important and constantly-growing branch of medicine, which deals with the prevention rather than the cure of disease, depends no less upon science, for tracking the dependence of one event upon another is the essence of inductive science. All efficient measures for the preservation of health, whether by individuals or communities, rest upon exact knowledge of the natural course of diseases. In fact, disease may be defined as the reaction of the human organism under conditions which make for its destruction. We must never forget that no irritant will cause inflammation in a lifeless skin; that no bacteria can produce fever without a nervous system to play upon; that no meal, however Gargantuan, and no potations, however deep, can produce their wonted effect without a stomach to react. The infection of small-pox, of diphtheria, or of tubercle exerts a very different influence upon vaccinated or unvaccinated subjects, upon one who has received and one who has not received the prophylactic serum, upon an organism which is predisposed to or refractory against the invasion of the enemy. How closely natural science is related to preventive medicine is shown by the history of Jenner, who was a naturalist, and of Pasteur, who was a chemist. How dependent we are upon science is well illustrated by the history of myxœdema. The cretinoid condition in adults which was discovered by the clinical acumen of Sir William Gull, unintentionally produced by the surgical skill of Prof. Kocher, and reproduced in animals by Mr. Horsley, is now cured by the eminently scientific method due to Dr. Murray, of Newcastle, and to Dr. Hector Mackenzie, of St. Thomas's Hospital. Such examples of accurate tracing of causation by observation and experiment admonish us to give up the perfunctory explanations which so often do duty for investigation. If we ascribe every inflammation to cold, and every vague complaint to gout; if we acquiesce in the popular ascription of disease to over-work, mental strain, and the nervous tension of modern life, we shall make no progress in true ætiology. I see many patients suffering from idleness—few, or none, from hard work. "Nerve-prostration" from "worry" and "brain-tension" often proves a decent synonym for the effects of gambling and drink. Modern life is easier, safer, and smoother than it was a hundred years ago. Our young men and maidens are healthier, stronger, better grown, less hysterical and sounder in mind and body than their great-grandparents. I venture to think that the duty of a physician is not to flatter the self-love of neurotic patients, but to inspire fortitude, and to prescribe regular and steady work as the best cure for a thousand nervous ailments.

As another point in scientific ætiology, allow me to warn against the temptation to assume that because many diseases are now proved to depend upon the presence of bacteria this must be true of all. Science does not anticipate, but waits for proof. We have complete scientific evidence, according to the criteria so well formulated by Koch, of the absolute and constant cause of anthrax, of relapsing fever, of tubercle, and several other diseases in both men and animals; but we must not forget the preliminary difficulty of identifying the specific bacillus—as in the case of enteric fever and diphtheria—nor the difficulty of finding one of the lower animals which is susceptible to the disease, as again in the case of typhoid fever and of cholera; nor the difficulty of the same anatomical and clinical conditions being produced by different organisms, as in the case of pneumonia and ulcerative endocarditis. Moreover, while in some diseases, which are undoubtedly infective and specific, no constant pathogenic microbe has yet been determined—as in typhus, measles, small-pox, and syphilis—we have, on the other hand, in the case of leprosy and of lupus, examples of disease unquestionably specific and bacterial in origin, but very unlike other infective maladies in their clinical course and natural history. At present it is surely undesirable to speak of "the undiscovered microbe of rheumatism." Science has to do with proved facts alone, and our language should never outrun our knowledge.

*Experiments in Scientific Medicine.*—There is one aspect of scientific medicine so important that it must not be omitted—the necessity of experiments for the progress of pathology, and, through it, for the prevention and cure of disease. It requires no argument to convince any one who is the least acquainted with the principles of inductive science that experiment is no less necessary than observation. In physics and in chemistry this is obvious and universally acted on. The same method is indispensable for the progress of animal and vegetable physiology, and to such practical applications of science as engineering, agriculture and medicine. Nor can experiments be restricted to rare occasional and solemn occasions; they must be carried on in large numbers, by many different experimenters, and under every variety of condition. Any attempt to abolish, to check or to limit this experimental work is, in the degree that it is successful, fatal to progress. Happily it can never be successful, for the impulse to increase knowledge of the works of creation is too deeply implanted in men. Investigation must and will go on by the only path which it can follow. The method which was preached by Bacon and followed out by his great contemporary, William Harvey, which was continued by Lower, Hooke and Mayow in the early days of the Royal Society, by Aselli, Malpighi and Haller, by Hunter, Hewson and Hales, by Edward Jenner, by Sir Charles Bell, by Johannes Müller, by Claude Bernard, by Ludwig, and by the many eminent physiologists and pathologists in Germany, in France and throughout the civilised world, this method of investigation is absolutely necessary for the progress of our science and the improvement of our art. As its objects and methods are better understood, it will secure the enlightened patronage of all who desire the diffusion of human knowledge and the further spread of human happiness. Fortunately this very progress of science has brought with it the removal of the one grave drawback, as every right-thinking man must have felt it, to the benefits of these experiments upon living animals. Inflicting pain upon the humblest of God's creatures is repugnant to our feelings, though no one, unless maintaining a thesis, would contend that it is wrong to exact the most painful efforts, or even the death from exhaustion of a horse in order to carry help to a human being. But the discovery of ether, chloroform, and other anæsthetics, and the improved methods that we owe to the genius of Lister, have not only relieved the surgeon of the most repulsive part of his duties, but have relieved the experimenter also. Except in the investigation of the action of new remedies or in the inoculation of infective diseases, both of which inflict discomfort of a limited degree and duration rather than anything that can be described as pain, the experiments of the laboratory, whether physiological, pathological or therapeutical, are conducted without inflicting pain. The opposition to them has not succeeded, and is sure to diminish. However mistaken our opponents, we are glad to find there is even exaggerated jealousy to avoid anything approaching to cruelty. This legitimate object our more candid critics may be assured is already amply provided for.

## MR. BALFOUR ON SCIENTIFIC PROGRESS.[1]

APART altogether from individual likes and dislikes, is there any characteristic note which distinguishes this century from any that have gone before it?

On this point I range myself with those who find the characteristic note in the growth of science. In the last 100 years the world has seen great wars, great national and social upheavals, great religious movements, great economic changes. Literature and art have had their triumphs, and have permanently enriched the intellectual inheritance of our race. Yet, large as is the space which subjects like these legitimately fill in our thoughts, much as they will occupy the future historian, it is not among these that I seek for the most important and the most fundamental differences which separate the present from preceding ages. Rather is this to be found in the cumulative products of scientific research, to which no other period offers a precedent or a parallel. No single discovery, it may be, can be compared in its results to that of Copernicus; no single discoverer can be compared in genius to Newton; but, in their total effects, the advances made by the nineteenth century are not to be matched. Not only is the surprising increase of knowledge new, but the use to which it has been put is new also. The growth of industrial invention is not a fact we are permitted to forget. We do, however, sometimes forget how much of it is due to a close connection between theoretical knowledge and its utilitarian application which, in its degree, is altogether unexampled in the history of mankind. I suppose that, at this moment, if we were allowed a vision of the embryonic forces which are predestined most potently to affect the future of mankind, we should have to look for them, not in the Legislature, nor in the Press, nor on the platform, nor in the schemes of practical statesmen, nor the dreams of political theorists, but in the laboratories of scientific students whose names are but little in the mouths of men, who cannot themselves forecast the results of their own labours, and whose theories could scarce be understood by those whom they will chiefly benefit.

I do not propose to attempt any sketch of our gains from this most fruitful union between science and invention. I may, however, permit myself one parenthetic remark on an aspect of it which is likely more and more to thrust itself unpleasantly upon our attention. Marvellous as is the variety and ingenuity of modern industrial methods, they almost all depend in the last resort upon our supply of useful power; and our supply of useful power is principally provided for us by methods which, so far as I can see, have altered not at all in principle, and strangely little in detail, since the days of Watt. Coal, as we all know, is the chief reservoir of energy from which the world at present draws, and from which we in this country must always draw; but our main contrivance for utilising it is the steam engine, and, by its essential nature, the steam engine is extravagantly wasteful. So that, when we are told, as if it was something to be proud of, that this is the age of steam, we may admit the fact, but can hardly share the satisfaction. Our coalfields, as we know too well, are limited. We certainly cannot increase them. The boldest legislator would hesitate to limit their employment for purposes of domestic industry. So the only possible alternative is to economise our method of consuming them. And for this there would, indeed, seem to be a sufficiency of room. Let a second Watt arise. Let him bring into general use some mode of extracting energy from fuel which shall only waste eighty per cent. of it, and lo! your coalfields, as sources of power, are doubled at once. The hope seems a modest one, but it is not yet fulfilled; and therefore it is that we must qualify the satisfaction with which at the end of the century we contemplate the unbroken course of its industrial triumphs. We have, in truth, been little better than brilliant spendthrifts. Every new invention seems to throw a new strain upon the vast, but not illimitable, resources of nature. Lord Kelvin is disquieted about our supply of oxygen; Sir William Crookes about our supply of nitrates. The problem of our coal supply is always with us. Sooner or later the stored-up resources of the world will be exhausted. Humanity, having used or squandered its capital, will thenceforward have to depend upon such current income as can be derived from that diurnal heat of the sun and the rotation of the earth till, in the sequence of the ages, these also begin to fail. With such remote speculations we are not now concerned. It is enough for us to take note how rapidly the prodigious progress of recent discovery has increased the drain upon the natural wealth of old manufacturing countries, and especially of Great Britain, and, at the same time, frankly to recognise that it is only by new inventions that the collateral evils of old inventions can be mitigated; that to go back is impossible; that our only hope lies in a further advance.

After all, however, it is not necessarily the material and obvious results of scientific discoveries which are of the deepest interest. They have effected changes more subtle and perhaps less obvious which are at least as worthy of our consideration and are at least as unique in the history of the civilised world. No century has seen so great a change in our intellectual apprehension of the world in which we live. Our whole point of view has changed. The mental framework in which we arrange the separate facts in the world of men and things is quite a new framework. The spectacle of the universe presents itself now in a wholly changed perspective. We not only see more, but we see differently. The discoveries in physics and in chemistry, which have borne their share in thus re-creating for us the evolution of the past, are in process of giving us quite new ideas as to the inner nature of that material whole of which the world's traversing space is but an insignificant part. Differences of quality once thought ultimate are constantly being resolved into differences of motion or configuration. What were once regarded as things are now known to be movement. Phenomena apparently so wide apart as light, radiant heat and electricity, are, as it is unnecessary to remind you, now recognised as substantially identical. From the arrangement of atoms in the molecule, not less than their intrinsic nature, flow the characteristic attributes of the compound. The atom itself has been pulverised, and speculation is forced to admit as a possibility that even the chemical elements themselves may be no more than varieties of a single substance. Plausible attempts have been made to reduce the physical universe, with its infinite variety, its glory of colour and of form, its significance and its sublimity, to one homogeneous medium in which there are no distinctions to be discovered but distinction of movement or of stress. And although no such hypothesis can, I suppose, be yet accepted, the gropings of physicists after this, or some other not less audacious unification, must finally, I think, be crowned with success. The change of view which I have endeavoured to indicate is purely scientific, but its consequences cannot be confined to science. How will they manifest themselves in other regions of human activity, in literature, in art, religion? The subject is one rather for the lecturer on the twentieth century than for the lecturer on the nineteenth. I, at least, cannot endeavour to grapple with it.

---

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, June 14.—"The Electrical Effects of Light upon Green Leaves." By Augustus D. Waller, M.D., F.R.S.

In the preliminary communication recently made to the Royal Society, the author shows how, from the study of the electrical effects of light upon the retina, he was led to ask whether the chemical changes aroused by the action of light upon green leaves are also accompanied by electrical effects demonstrable in the same way as the eye currents. The question is tested in the following way:—A young leaf freshly gathered is laid upon a glass plate and connected with a galvanometer by means of two unpolarisable clay electrodes A and B. The half of the leaf connected with A is shaded by a piece of black paper. An inverted glass jar forms a moist chamber to leaf and electrodes, which are then enclosed in a box provided with a shuttered aperture through which light can be directed. A water trough in the path of the light serves to cut out heat more or less. Under favourable conditions there is obtained with such an arrangement a true electrical response to light, consisting in the establishment of a potential difference between illuminated and non-illuminated half of a leaf, amounting to 0·02 volt.

The deflection of the galvanometer spot during illumination is such as to indicate current in the leaf from excited to protected part. The deflection begins and ends sharply with the beginning and end of illumination; it is provoked slightly by diffuse daylight, more by an electric arc-light, most by bright sunlight. It is abolished by boiling the leaf, and by the action of an anæsthetic, carbon dioxide.

---

[1] Address delivered by Mr. Balfour, M.P., at the opening of the Cambridge Summer Meeting on August 2. Abridged from the *Times*.

The first experiments, made at the end of March, were upon iris leaves taken from plants about 6 inches high, and the response to light was then between 0·001 and 0·002 volt in value. Experiments upon similar leaves were resumed early in May, when it appeared that the external condition by which the state of the leaf is most obviously governed is *temperature.* On warm days the response ranged from 0·005 to 0·02 volt; on cold days it did not rise above above 0·005, and was sometimes nil. Some tests upon leaves in a warmed box gave satisfactory results, which may be thus summed up:—The normal response at 15°–20° C. is diminished or abolished at low temperature (10°), augmented at high temperature (30°), diminished at higher temperature (50°), and abolished by boiling.

As the month of May advanced, the iris leaves, even in the warm box, became more and more inert, and by the 23rd inst., when the plants were mostly full grown and in flower, no satisfactory leaf could be found. Leaves of iris appear to give more marked response at or about mid-day, than at or about 6 p.m. Tested by Sach's method the leaves gave no evidence of starch activity during insolation.

On the failure of the iris leaves to react, other leaves were sought for which should give evident differences of reaction in correlation with evident differences of state. Leaves of tropæolum and of mathiola gave a response to light contrary in the main to the ordinary iris response, viz. "positive" during illumination, and subsequently "negative."[1] In these two cases leaves empty of starch acted better than leaves laden with starch. Leaves of begonia gave a variety of responses strongly suggestive of the simultaneous action of two opposed forces effecting a resultant deflection in a + or − direction. Leaves of ordinary garden shrubs and trees, &c., *e.g.* lilac, pear, almond, mulberry, vine, ivy, gave no distinct response; this is possibly due to a lower average metabolism in such leaves as compared with the activity of leaves of small young plants in which leaf-functions are presumably concentrated within a smaller area. The petals of flowers gave no distinct response, which indicates that chloroplasts are essential to the reaction.

The effect of carbon dioxide upon the iris leaf was abolition of response during and after passage of the gas, with subsequent augmentation. Upon mathiola and tropæolum, augmentation of response followed on applying air containing 1 to 3 per 100 of carbon dioxide, and prompt abolition resulted from a full stream run through the leaf-chamber. On the air supply being kept clear of carbon dioxide there was gradual abolition of response, followed by gradual recovery on the re-admission of a small amount of carbon dioxide.

"Fatigue" effects may be produced if the successive illuminations (of 5 minutes duration) are repeated at short intervals (10 minutes). At intervals of 1 hour, successive illuminations of 5 minutes produce approximately equal effects. With the leaf of mathiola, periods of illumination of 2 minutes at intervals of 15 minutes were used without provoking any obvious sign of fatigue.

June 21.—"Note on Inquiries as to the Escape of Gases from Atmospheres." By G. Johnstone Stoney, M.A., Hon. D.Sc., F.R.S.

Three investigations have been published which profess to supply information about the escape of gases from atmospheres. Two of them, those of Messrs. Cook[2] and Bryan,[3] while differing in other respects, agree in reasoning forwards by the help of the kinetic theory of gas from the supposed causes; the third[4] pursues a method regarded as trustworthy by the present writer, and reasons backwards by the help of the same theory from the observed effects.

Where, as in the present instance, the *a priori* and *a posteriori* methods have led to inconsistent numerical results, it is incumbent upon us to search for the mistake or mistakes which must somewhere have been made. If these can be found and corrected, an important advantage is gained; and the present is an attempt to trace some of them by inquiring whether there are conditions or agencies in nature which facilitate the escape of gaseous molecules from the earth, and which are omitted, or which have not been sufficiently taken into account, in Mr. Cook's and Prof. Bryan's investigations.

Let $\Delta V$ be a volume containing at a given epoch a large number $n$ of molecules of the atmosphere, and let $\Delta t$ be a duration commencing at that instant. Also, let $n'$ be the number of encounters which each of these molecules on the average meets with in the times $\Delta t$. Then will

$$N = nn'$$

be the total number of their free paths in that time; and the actual number of these free paths, in which the initial speed after an encounter lies at the time $t$ between $v$ and $v + dv$, must be precisely

$$dN = N(\pi + \delta)dv, \qquad (1)$$

where $\pi$ is the probability function (that employed by Mr. Cook, or that employed by Prof. Bryan, or some other), and $\delta$ (the deviation function) represents whatever is the real divergence of the actual number from that computed by the formula used by them, viz.:

$$dN = N\pi dv; \qquad (2)$$

in other words, computed on the supposition that $\delta/\pi$ is of negligible amount.

Now $\pi$ is one fully-determined function in Mr. Cook's investigation, and another fully-determined function in Prof. Bryan's; but little is known of what $\delta$ is in either case, except that it is in both an excessively complex function of $N$, $v$, $t$, with several other variables, some of which it is difficult even to indicate; and that by its amount for any given value of $t$ and at any given position in the atmosphere it must supply in equation (1) the actual effect, at that time and place, of all natural agencies which had not been taken into account in calculating the expression $\pi$.

If due care has been taken in framing the probability law $\pi$, it will in many cases be legitimate to assume that $\delta/\pi$ is sufficiently small to warrant our using equation (2) when computing the approximate distribution among the free paths of those speeds which assign *large* values to $\pi$, while at the same time it may need proof and may not be a legitimate assumption in reference to those values of $v$ which make $\pi$ *small*. Now it is in this latter case that the assumption has to be made by Mr. Cook and Prof. Bryan.

The conditions under which the assumption is likely not to be true are the following:—

A. Where the events, the law of whose distribution purports to be represented by the $\pi$ function, are of such a kind that a vast number of the events need to be passed under review in order to secure an approximate conformity to *any* fixed law. Now experiment shows that in ordinary air trillions of the free paths, probably many trillions, must be grouped together in order to make manifest any law in the distribution of the speeds. In all such cases we are not entitled to ignore the $\delta$ function, except in estimating the frequency of such speeds as can be shown to assign a sufficient preponderance to the $\pi$ function. Accordingly it is not legitimate to ignore the $\delta$ function when treating of the frequency of speeds which make $\pi$ excessively small, such as are the speeds which carry molecules away from the earth.

B. But a more important omission occurs where the function $\pi$ has been arrived at without taking into account agencies in nature which affect the distribution of speeds. Where this has been done the $\delta$ function must include the whole effect of these agencies, and this again forbids our relying upon equation (2) in computing the frequency of any speed which makes the value of $\pi$ small.

B 1. Thus in Mr. Cook's computation no notice is taken of the anisotropic character of the outer strata of the earth's atmosphere, which facilitates the escape of molecules. In Prof. Bryan's this is partly taken into account by treating the molecules as moving in a constant field of force. This may possibly be sufficient, though it ignores the reactions which are also necessarily present. To include them it would be necessary to extend the partition of energy beyond the molecules of the atmosphere to all the other molecules of the earth which attract them.

B 2. Then, again, both computations ignore the incessant turbulence of the atmosphere which, in its lower strata, produces all the phenomena of weather, and in its upper regions phenomena which are swifter and on a larger scale. This turmoil, with all its dynamical, thermal and electrical effects, is due, like most other events upon the earth, to the shiftings about of energy which intervene between the advent of energy and from the sun and its radiation from the earth into space; and to take it into account in an investigation based on the laws of the partition of energy, it would be necessary to extend that partition beyond the earth to the sun and to the intervening æther.

---

[1] "Negative" as the term is employed in physiological literature, *i.e.* negative pole of positive element ("zincative").

[2] *Astrophysical Journal* for January 1900.

[3] *Roy. Soc. Proc.*, April 5, 1900, p. 335.

[4] *Scientific Transactions of the Royal Dublin Society*, vol. vi. Part 13; or *Astrophysical Journal* for January 1898. And for further evidence that helium is escaping from the earth, see NATURE of May 24, 1900, p. 78.

B 3. So, again, the great absorption of solar radiation which takes place in the outer layers of the earth's atmosphere will have to be taken into account, and as it has not been included under function $\pi$, it still further augments the part which the $\delta$ function takes in equation (1) and renders equation (2) an insufficient one for the purposes of the investigation.

B 4. The commotion going on in the atmosphere consists in part of electrical phenomena. Some of these—thunderstorms, auroras, the electrical condition of fogs, &c.—can be observed from the stations which men occupy at the bottom of the atmosphere, and are of such a kind that they must be accompanied by a charged condition of that stratum of the atmosphere the density of which renders it a better conductor than the atmosphere above it and below. This stratum, then, and the strata above it receive charges of electricity which, according to the varying condition of the strata further down, will sometimes be disguised electricity and at other times undisguised. This electrified condition of the upper regions, co-operating with ascending currents, which necessarily increase in speed as they advance, will presumably give rise to prominences upon the earth's atmosphere, upon which the density of the electrification will be intensified and from which in consequence gaseous molecules find it easier to escape than from other situations. In this and other ways electricity may help the escape.

Now of these agencies, all of which affect the rate at which gas can escape from the earth, none is included in the investigation which Mr. Cook has made of that phenomenon; and only the first (B 1) is dealt with by Prof. Bryan. Moreover, it is probable that these are not the only ways in which nature can intervene, and which have been overlooked. The supposition then that either of the probability laws made use of by those investigators can be applied to our actually existing atmosphere, without a large correcting function $\delta$, would appear to be a mistake; and, if so, the inferences from those laws when so applied are not part of a real interpretation of nature. It need not therefore occasion any surprise that, in the case of helium, the facts of nature seem to negative those inferences. (See NATURE of May 24, 1900; the second column of p. 78.)

### EDINBURGH.

**Royal Society,** July 16.—Lord Kelvin, President, in the chair.—Lord Kelvin read a paper on the motion in an infinite elastic solid by the motion, through the space occupied by it, of a body acting on it only by attraction and repulsion. The ideal atom considered in this paper was a region of space in which the ether was changed in density by the action of forces upon it. In the particular case chosen for development the atom was taken as spherical with spherical distributions of density within it, and every element of matter was supposed to act on every element of the ether according to the Newtonian law. The further assumption was made that the average density of the ether within the atom was the same as if the atom were not present. The atom and the ether were then supposed to be in relative motion, and the total kinetic energy of the ether within the atom was calculated, as also the effective inertia of the ether in the space occupied by the matter. On the assumption that the density of the ether at the centre of the atom was 101 times greater than the undisturbed density, it was found that a refractivity was obtained a little smaller than that of oxygen. By assuming that the average density was in excess or defect of the undisturbed density of the ether, we could extend the method so as to include electrical actions.—In a second paper, on the number of molecules in a cubic centimetre of gas, Lord Kelvin pointed out that in the preceding paper he had been obliged to take the number as $4 \times 10^{20}$ instead of Maxwell's number, $19 \times 10^{18}$.—In a paper on the hyperbolic quaternion, Dr. Alex. Macfarlane showed how by the introduction of "real" instead of "imaginary" vectors, quaternion theorems of spherical geometry could be generalised so as to be applicable to hyperbolic geometry.—Sir John Murray and Dr. Philippi communicated a preliminary note on the deep-sea deposits collected during the *Valdivia* expedition of 1898–9. Leaving Hamburg and passing round by the north of Scotland, the *Valdivia* proceeded southwards by the west coast of Africa to the Cape, thence to the Antarctic seas, returning by way of the Indian Ocean and the Suez Canal. Generally speaking, the nature of the deposits agreed with what was already known, but fuller information was gained in many instances. For example, off the mouth of the Congo samples of coprolitic mud had been obtained, largely made up of little oval pellets of mud which had passed through the intestines of echinoderms. These had consolidated and were apparently in the process of being transformed into glauconitic and phosphatic concretions. The study of the formation and distribution of glauconite was geologically of great importance, and a detailed examination of the *Valdivia* collections would probably throw much light on the subject.—Prof. J. C. Beattie communicated a second part of his researches into the leakage of electricity from charged bodies at moderate temperatures. In most of the experiments described, zinc strips resting on insulated iron plates were sprinkled with various salts and then heated to about 350° C., the whole being enclosed in an iron box which was connected to the case of the electrometer. Among the substances used were common salt, alone or with iodine or bromine, and similar combinations with the chlorides of lithium, lead, potassium, &c. Generally a steady negative charge was produced by the heating, but not always. The difference of potential so obtained depended on the nature of the insulated metals, but not on their distance apart. When high voltages were used, the positive charge leaked away, while the negative charge was retained. An explanation was offered founded on Enright's and on Townsend's experiments.—A communication was also presented by Dr. Thomas Muir on the theory of skew determinants and pfaffians in the historical order of its development up to 1857.—In a brief review of the session, the President referred to the great losses the Society had sustained through the deaths of the Duke of Argyll and Sir Douglas Maclagan.

## A STANDARD TEXT-BOOK OF PHYSICS.

*Müller-Pouillet's Lehrbuch der Physik und Meteorologie.* Neunte umgearbeitete und vermehrte Auflage von Dr. Leopold Pfaundler. In drei Bänden. Erster Band, Mechanik, Akustik. Pp. xxi + 888 (1886). Zweiter Band, unter Mitwirkung des Dr. Otto Lummer, Erste Abtheilung, Optik. Pp. xx + 1192 (1894–1897). Zweite Abtheilung, Wärme. Pp. xiv + 768 (1898). Dritter Band, Elektrischen Erscheinengen. Pp. xvi + 1062 (1888–1890). (Braunschweig: Friedrich Vieweg und Sohn.)

THE appearance of the second part of the second volume of this work marks the completion of the ninth edition of an important treatise on experimental physics which has for many years been widely used in Germany. The importance of the work lies in the fact that it aims at giving a full description of physical apparatus and experimental methods, no attempt being made to expound mathematical theories, and none but the most elementary mathematics being employed or assumed as one of the reader's acquirements.

Herein the work differs from most of our English text-books of physics, in which the tendency has latterly been to combine a certain amount of mathematical theory with short accounts of experiments in illustration of the theory, both the mathematical and experimental portions being of necessity very incomplete. This tendency, probably necessitated by our examination system, will, as long as it continues, prevent our having in English such complete works on experimental physics as that now before us.

Any work on physics, however, in several volumes produced at different times, must, when completed, present some lack of uniformity among its parts, especially if the part dealing with that branch of the subject which varies most rapidly is not produced last. This is the case in the present instance. The volume on magnetism and electricity was published some ten or twelve years ago, several years before the appearance of the volumes on light and heat. The reason given is that, on account of the rapid advance made in electricity, the volume dealing with this branch in the previous edition appeared much more out-of-date than the other volumes, and therefore had more need of revision. For the same reason, on now reviewing the whole of the present edition, one cannot help being struck with the fact that the volume dealing with electricity and magnetism far less adequately represents the present state of the subject in this branch than do the other volumes in their own regions.

In the first volume of the present edition, dealing with mechanics and sound, after an introductory chapter on fundamental notions and a short discussion of uniform and uniformly accelerated motion of a point in a straight line, the subject of mass and force is immediately taken up, further treatment of kinematics being postponed to a later stage. It seems to the writer to be preferable, especially in an elementary book on the subject, to deal more fully with kinematics before going on to dynamics proper. The student should first become well acquainted with the notions of velocity, acceleration, their composition and resolution, and should give special attention to cases in which the acceleration is not in the same direction as the velocity. In this way he is enabled to acquire a much clearer idea about acceleration as a quantity with a direction of its own, and is therefore much better prepared to make the transition from his previous vague notion of force to the more accurate dynamical meaning of the term.

The subject of mass and its measurement is discussed at some length, and in a very instructive manner. The action of a force in producing acceleration in a body is finally adopted as the basis of the dynamical measurement of mass. This system involves the definition of force. A definition of mass (due to Mach) independent of the definition of force is referred to in a footnote on p. 85, viz.: bodies which (by gravitation) produce equal but opposite accelerations in each other are said to have equal masses. This includes the definition of the ratio of the masses of two bodies as the ratio of the accelerations which they produce in each other, and when a unit of mass is chosen, the mass of any other body is measured by the acceleration given to the unit divided by the acceleration experienced by the body itself.

The phraseology is sometimes not as accurate as one could wish; thus on p. 92 we find the expression "an acceleration of one metre," and in the following sentence, "a velocity of one metre"; and again, the kilogramme is stated to be both the unit of mass and the gravitational unit of force. Although explanations follow, it must lead to some confusion in the mind of a beginner to find that a kilogramme means sometimes a mass and sometimes a force. It is of the greatest importance in an exposition of the principles of dynamics that one meaning only should be attached to every technical term. A similar confusion arises in connection with the term "weight," about which there is a lengthy discussion on pp. 96–99. The difficulty might have been much diminished by reserving the word kilogramme to mean a mass and weight to mean a force—viz. the resultant force acting on a body falling freely near the earth. The common use of the terms should be explained afterwards.

On pp. 326–333 a short account is given of the behaviour of spinning tops and gyroscopes, with a general explanation of the couples called into play by a deflection of the axis of rotation. The "drift" of a shell fired by a cannon is ascribed mainly to gyrostatic action. The constantly increasing angle between the axis of rotation and the direction of motion causes the air in front of the shell to exert a force tending generally to raise the head of the shell with respect to the centre of mass; this produces a deflection of the point of the shell to the right, and the increased pressure thus introduced on the left side causes a deflection to the right. It is possible that, with a shell of suitable shape, the pressure of the air would tend to raise the rear end, and the gyrostatic deflection would in this case be to the left. As is remarked in a footnote, however, the greater friction on the under side of the shell probably plays an important part, and this always causes a drift to the right.

In Chapter v. a good elementary account of the laws of capillarity is given. On p. 444 Quincke's falling drop method of measuring surface tensions is described, the weight of the drop being stated to be equal to the product of the surface tension and the circumference of the line of contact. Lord Rayleigh has shown that this is not correct even if the liquid motion in the drop at the moment of separation be neglected; the excess of pressure in the drop corresponding to the curvature of the surface (supposed cylindrical near the plane of contact) has the effect of diminishing the size of the drop to one-half the value stated, and this result agrees more closely with experiment.

The second part of the volume, on sound, resembles in its general mode of treatment most other elementary text-books on the subject. The general nature of wave-motion is made quite clear by numerous diagrams of wave-curves and wave-machines. The deduction given on p. 638 of the expression $\sqrt{E/D}$ for the velocity of propagation of sound-waves is not satisfactory, since it involves the tacit assumption that the whole energy is half potential and half kinetic.

In connection with the experimental measurement of the velocity of sound in water in tubes, referred to on p. 643, the influence of the walls and Kundt's measurements in tubes with walls of different thicknesses should have been mentioned, and in the description of the resonance tube experiment, no method is given for eliminating the end correction.

The last chapter contains an interesting account of the researches of von Helmholtz and others on the vibrations of violin strings, combination tones, analysis of sounds, and the theory of consonance and dissonance.

In the second volume (light and heat) the author is assisted by Dr. Lummer, who, we are told in the preface, is chiefly responsible for the part dealing with optical systems and the theory of optical instruments. This part of the work has been largely re-written for the present edition, and brought well into line with the modern views on image-formation founded by Abbe.

As is the case in doing most things, there are two ways of writing a book on geometrical optics. The first, until recently the usual, method is to begin with very special cases, such as thin lenses, and proceed by degrees to the more general cases of thick lenses and systems of lenses.

The other, and more modern, method is to begin with the general case of a point-point correspondence between two portions of space, of such a kind that to a pencil of rectilinear rays passing through a point in one region corresponds a pencil of rectilinear rays passing through a point (the image) in the other region; then to introduce the special cases of image-formation by reflecting or refracting surfaces and centred systems, including lenses. The two methods thus proceed on opposite lines.

The latter method has been perfected by Abbe, and is the one adopted by Czapski and, though necessarily in a more elementary and restricted manner, in the present work.

After two chapters dealing with the nature of light, photometry, refraction and reflection at plane surfaces, Chapter iii. treats of the formation of images by refraction at a single spherical surface; then the general case of any number of spherical surfaces separating different media, with their centres in a straight line; and, finally, two coaxial centred systems, with the special case of a "telescopic" system in which the "interval" is zero. The lens is regarded as two centred systems, each consisting of a single spherical surface.

Chapter xii. is devoted to the theory and use of "stops," the calculation of magnifying power and brightness of images in centred systems, and, finally, the laws of formation of images of illuminated objects, as in the ordinary use of the microscope. Here purely geometrical methods break down, and diffraction spectra play an all-important part. A highly interesting account follows o Abbe's theory of microscope images and its remarkable verification by the use of the diffraction plate, in which is shown how the similarity of image to object, as well as the resolving power of the instrument, depends upon the number of diffraction spectra whose rays enter the objective and take part in the final image-formation. How these principles are applied in the construction of microscope-objectives is set forth in the chapter on optical instruments, which also contains details of many of the latest improvements in optical instruments of all kinds.

The second part of vol. ii. (on heat) does not differ from the corresponding part of the previous edition so fundamentally as is the case with the part on optics; but it is brought more nearly up-to-date by many additions, including the work of Olszewski and Linde on the liquefaction of gases, a chapter on thermochemistry, steam calorimeters, recent determinations of the specific heat of water at various temperatures and of the mechanical equivalent of heat. No reference is made, however, to recent improvements in the choice of a unit of heat.

Thermodynamics does not receive very much attention, few applications being mentioned beyond Kelvin's definition of absolute temperature, and a calculation of the change of melting point produced by pressure. Some details are given, however, of the parts and action of steam, air, and gas engines.

A short chapter on meteorology, dealing with climatic conditions and their changes, brings this volume to a close.

As to the third volume, it suffers, as was remarked before, in comparison with the other volumes from having been written several years ago. Still, it contains a large mass of useful information about electrical and electro-technical apparatus, much of which is not usually found in text-books on electricity and magnetism.

It is impossible, in the space at our disposal, to give more than a very rough sketch of a work which extends to close upon 4000 pages, and many excellent qualities of the work must for this reason remain unmentioned. One of the chief features is the large number (nearly 3000) of excellent illustrations, and, chiefly in the section on optics, some very beautiful coloured plates. Explanations are, as a rule, given very clearly, and often aided by numerical examples worked out. Further, on account of the very large number of experiments and forms of apparatus described, as well as the numerous references to original papers, the work is certain to prove useful, as it no doubt has already done, to students and teachers of physics.

## HUXLEY'S PHYSIOLOGY.

*Lessons in Elementary Physiology.* By Thomas H. Huxley, LL.D., F.R.S. Enlarged and revised edition. Pp. xxiv + 611. (London: Macmillan and Co., Ltd., 1900.)

HUXLEY'S "Lessons in Elementary Physiology" was probably the best book of its kind which has ever been written. It set forth the elements of human anatomy and physiology in so clear and concise a form, and the little volume formed so complete a compendium of the essential facts which had accumulated in the science with which it dealt, that it was at once welcomed as supplying a want which had long been felt—that of a popular and, at the same time, an authoritative exposition of the subject. Its success was enormous. Edition after edition was sold in rapid succession, and the booklet—for it was nothing more—was not only adopted in schools throughout this country as *the* text-book with which the teaching of physiology was to be begun, but it was soon translated into every civilised language, and even, it is said, into more than one barbaric tongue.

The secret of its success lies on the surface. It was written in the English which was characteristic of the Master: its language trenchant, flowing, and well chosen, its similes apposite, its facts duly marshalled and leading up to their logical conclusion. And the book was what it was intended to be—a popular account, which, while retaining scientific accuracy, should not be burthened by unnecessary details, nor by theories which might or might not ultimately prove correct. Moreover, the ground was clear—where there are now a dozen similar treatises, there was then not one. But it is safe to assert that "Huxley" would in any case have taken the first place.

An entirely new edition of the "Lessons"—the first since the lamented death of the original author—has now made its appearance under the auspices of Sir Michael Foster and Dr. Sheridan Lea. Michael Foster has been associated with the book throughout its whole career. Sheridan Lea's name appears now for the first time in connection with it; but although the responsibility is joint, the labours of preparation have fallen chiefly upon Dr. Lea's shoulders. We may be sure that the work has been a labour of love to the editors. The intimate friendship which existed between them and Huxley, their veneration for his memory, their desire to maintain the high standard and reputation of the work, must have caused them to put forth their best efforts to ensure its continued success.

In surveying the changes which have been introduced, the point of chief interest appears to be to notice whether the introduction of these changes has tended in any way to modify the original character of the work. We have already seen that this character was that of a popular exposition of the science suitable especially for schools, and the questions naturally arise, is the book still of this nature? Has it been modified to suit it to other purposes than that for which its author originally wrote it?[1] It must be conceded that the book retains in a measure its character as a popular expositor. This is largely owing to the fact that the editors have preserved "as far as possible the original author's own form of exposition and indeed his own words." But it must also be admitted that its character in this respect has been modified by changes and additions. The purport of these appears to have been to adapt the book for use by students of medicine, a design which may be laudable but cannot fail to affect the general tone of the work. Students of medicine require to learn anatomy and physiology with a minuteness of detail not necessary in a work which is intended to be of a popular nature. Not only is it important that the unquestioned facts of the science should be set before them, but they require also to be made cognizant of statements which, however probable, are not universally accepted as facts, and of theories which may or may not ultimately prove to be correct. And herein it appears to me lies the difference between the new "Huxley" and the old. That the change tends, as the editors claim, to increase the sphere of usefulness of the work, may be perfectly true, but the essential character and original aim of the work has been thereby affected. If there is a gain on the one side there is a loss on the other, and it is impossible that it should not be so; it is a question of opinion whether the gain counterbalances the loss. For my own part, while recognising the able manner in which the new material is worked up and incorporated with the old and the increased value which is thereby imparted to the work as a text-book preliminary to the study of physiology, I must frankly confess that I regret the change. Students of medicine have already more than one elementary text-book in which the facts and chief theories of physiology are set forth with all the clearness that could be desired, and in one instance at least with a wealth of illustration which cannot be surpassed or even approached in a book of so small a size as "Huxley." On the other hand, the amount of detail which has been introduced into this edition, while valuable for the medical student, is unnecessary or unsuitable for the school boy. Perhaps it was impossible to avoid this change, perhaps it was desirable to make it; at any rate it has been made, and as years go on the development of the book must proceed along the lines which have been now laid down. That it will be as successful on these lines as it has been upon the old ones may be confidently assumed so long as it remains under the management of the present editors, but I believe that my regret that the change has been introduced will be shared by most of those who remember the appearance of the original book in the late sixties and the enthusiasm with which it was then received.

E. A. SCHÄFER.

## THE GLUCOSIDES.

*Die Glykoside.* By Dr. J. J. I. van Rijn. Pp. xvi + 511. (Berlin: Gebr. Borntraeger, 1900.)

THE student of chemistry or botany, who may have attempted to grope his way through the tangle of chemical facts relating to plant products, will be grateful to the author of this exhaustive monograph on the glucosides, or *glykosides* as he prefers to spell it, where the latest information, with all the necessary references, is easily found.

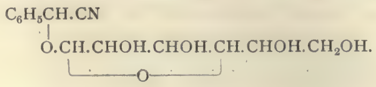
---

[1] "The following 'Lessons in Elementary Physiology' are primarily intended to serve the purposes of a text-book for teachers and learners in boys' and girls' schools."—*Extract from Preface to the First Edition*, 1866.

The study of the glucosides may be said to date from Liebig and Wöhler's remarkable discovery of the decomposition of amygdalin by its own ferment or enzyme emulsin. The discovery of other glucosides followed in fairly rapid succession. Among these may be mentioned, without reference to chronological sequence: salicin, derived from willow bark; populin, from aspen leaves; æsculin, from the bark of the horse chestnut; daphnin, from *Daphne mezereum*; phloridzin, from the bark of apple, pear and other fruit trees; hesperidin, from the fruit of limes, oranges and lemons; potassium myronate or sinigrin, from black mustard seed; ruberythric acid, from madder root, &c. They all undergo decomposition by a process of hydrolysis into grape sugar, and at least one other constituent drawn from such very varied groups of compounds as phenols, alcohols, aldehydes, mainly of the aromatic series, and in the case of black mustard seed, from a sulphocyanide. No trustworthy explanation of the constitution of these substances was, or could be, forthcoming until the structure of their proximate constituents had been ascertained.

The most important contribution to our knowledge of the glucosides in recent years has been undoubtedly that of Emil Fischer in his classical researches on the sugars. The formation of the glucosides of the simple alcohols and phenols, and of similar compounds of the mercaptans and ketones, has not only given a valuable clue to the structure of the natural products, but has revealed the close analogy which exists between these compounds and the members of the disaccharoses (cane and milk sugar and maltose). Moreover, the identification of new sugars has led to the successful search for these substances among the glucosides and other plant products. Rhamnose or methyl pentose is found to replace glucose in several glucosides: quercitrin, hesperidin, frangulin, baptisin, datiscin, &c., whilst chinovose, another pentose, is contained in chinovite.

Many other interesting points have arisen. The hydrolysing action of the enzyme accompanying one glucoside has been shown, not to be confined to that glucoside, but to extend to others, although, at the same time, strictly limited to a particular series of compounds. The enzyme of yeast has in a similar way been recognised as not exclusive, although restricted in its hydrolysing power. The action of emulsin and yeast on amygdalin is instructive. Emulsin effects complete hydrolysis of the glucoside into benzaldehyde hydrocyanic and two molecules of glucose, whereas the enzyme of yeast only removes one glucose group. Fischer, who discovered this curious difference between the two enzymes, has allotted the following formula to the second product:



$$\begin{array}{l} C_6H_5CH.CN \\ \;| \\ O.\underbrace{CH.CHOH.CHOH.CH}_{O}.CHOH.CH_2OH. \end{array}$$

The splitting off of more than one molecule of glucose on hydrolysis occurs with populin, hesperidin, helleborin and others.

All these facts are recognised and carefully recorded in the volume before us.

The work is divided into two parts. The first part deals with the artificial glucosides; the second, with the natural products. In the first part, the compounds are arranged in a strictly chemical order; in the second, according to the natural order of plants. In reference to this arrangement, the author lays stress on the fact that the study of the constituents of plants should not follow a chemical classification, but should include all compounds occurring in the same natural order; because, he explains, it is only in this way that the chemical, morphological and anatomic properties will appear in their true light. The goal of the chemist should not be determined by purely utilitarian motives, but Rochleder's principle should be borne in mind that "the relationship of plants is determined by compounds of the same chemical nature which they contain."

There are one or two points mentioned in the book which are new to us, and may interest our readers. It appears now that sinigrin, the glucoside of black mustard seed, is not hydrolysed, as usually represented in text-books, without the addition of the elements of water; but the glucoside contains one molecule of water $C_{10}H_{16}NS_2KO_9 + H_2O$, and the decomposition then falls into line with the hydrolysis of other glucosides,

$$C_{10}H_{16}NS_2KO_9 + H_2O = C_3H_5NCS + C_6H_{12}O_6 + KHSO_4.$$

According to Beyerinck, indigo does not occur in the oldest of the indigo plants (*Isatis tinctoria*) as the glucoside indican, as usually stated; but in the form of indoxyl, which rapidly oxidises to indigo in contact with air; whilst the glucoside indican which is found in *Indigofera leptostachya* and *Polygonum tinctorium* may be extracted and left in contact with air without undergoing any change in the absence of enzymes and bacteria.

## AN OXFORD TEXT-BOOK.

*An Introduction to the Study of the Comparative Anatomy of Animals.* By G. C. Bourne, M.A., F.L.S. Vol. i. Pp. 258. (London: G. Bell and Sons, 1900.)

THIS admirable little book is designed to meet the requirements of the elementary examinations of the leading universities of Great Britain, and though of necessity largely concerned with creatures upon which laboratory treatises exist in abundance, it has been so framed as to supplement and not supersede certain of these, the author having aimed at "the lessons that may be learned and the conclusions which may be drawn" rather than the detailed description of the facts themselves. The work opens with an "Introduction," in which it is pointed out that in the study of natural science, as in other things, something of the nature of a creed is necessary for action, and there is given a definition of "evolution," on the basis of the principles involved in which the science of comparative anatomy is said to be founded. Passing on to treat of the elementary principles of morphology and physiology, the author proceeds to deal with the anatomy of the frog, the elements of histology of the Vertebrata, the cell and cell theory, and phenomena of development up to the formation of the germinal blastemata. The Protozoa are next dealt with, including the Mycetozoa and Volvocinæ; and, *apropos* of Volvox and Zoothamnium, there follows a chapter on the Protozoa and Metazoa, with a discussion of their inter-relationships. The Cœlenterata follow based on the study of Hydra and Obelia, with a concluding chapter on classification. The book is novel in conception, accurate, up-to-date, and thoroughly artistic in execution. Bütschli on the "Schaumplasma," Boveri on the Ascaris egg, Maupas on the Ciliata, Keuten on Euglena, Hertwig on Actinosphærium, the mitotic processes in Amœba bi-nucleata, the immortality of the Protozoa, are conspicuous among topics of the times handled in a manner well calculated to arouse the imaginative faculty, which, under our prevailing systems of elementary biological training, is apt to be ignored. Unlike many of its predecessors and contemporaries, the book is written in choice English. It is in places even racy; and in such paragraphs as those in which the author unfolds the points of dissimilarity between Vertebrate and Invertebrate (dog, fish, and lobster), a perspicuity is noticeable equal to that of a good French writer at his best. It recalls most nearly the irresistible charm of the late M. Paul Bert's "Première Année d'Enseignement Scientifique."

The illustrations, fifty-three in number, are mostly original and altogether admirable, and those of the Hydra, based on the author's unpublished researches, will unquestionably become popular—that of the median longitudinal section of this animal being the best we know. On p. 47 the author gives two new figures of the frog's heart, which, as regards the detailed structure of the pylangium and the ostia of the carotid and pulmocutaneous arteries, are wholly unconventional. It is explained in the preface that these are drawings of reconstructional models from sections, and we dare not doubt their accuracy. The question, however, arises how far the facts they reveal may be true of but one individual; and the author would have done well to have either intimated this or left the matter aside till further investigated. Again, we regret the too forced introduction of analogy to the inanimate, as, for example, of the nervous system to the telegraphic apparatus. In this, however, the author is but acting in the spirit of the times. His book is simply charming and well worthy his reputation; and while its literary style should alone ensure for it a wide circulation, it cannot fail to exercise a leavening and humanising influence on the youthful mind. It is to be followed by a second volume, dealing with the Cœlomate Metazoa, and the sooner this appears the better for biological science and culture.

## *OUR BOOK SHELF.*

*The Ore Deposits of the United States and Canada.* By J. F. Kemp. Pp. xxiv + 462; index and 163 illustrations. Third edition. (New York and London: The Scientific Publishing Company, 1900.)

OF Prof. Kemp's industry as a compiler there can be no question. The last edition of his work on ore deposits is teeming with information, and his footnotes alone are a proof of the thoroughness with which he has conducted his search after facts. But it is not a book which appeals to the elementary student, because he is launched into a mass of details without sufficient preparation in the introductory part, which is sadly lacking in woodcuts. And further, there is evidence of haste or want of care in correcting the book for the press. Surely a writer on ore deposits should be able to spell such names as "Pošepný," "Sjögren" and "Přibram" with strict accuracy. Errors in spelling ordinary French and German words are frequent, and when one notes as many as nine mistakes in seven consecutive lines, there are fair grounds for complaint. It is not only in his spelling that Prof. Kemp evinces carelessness. A mineralogist would not speak of specular iron as "specular hematite"; the product of a zinc mine should not be called *spelter*, as the word denotes the metal, not the ore. By one of his sentences, one might infer that Prof. Kemp would not admit sulphide of sodium among the metallic sulphides. It is not good English to say: "*Considerable* limonite has also resulted from the weathering of clay-ironstone nodules."

In spite of frequent and unpardonable minor blemishes, which could easily have been avoided by employing a careful proof-reader, the book will be found very useful by those who require a summary of the innumerable memoirs and papers describing American ore deposits.

Prof. Kemp's conclusion that an amendment is needed of the laws regulating the tenure of ore deposits in the Western States will be warmly endorsed by most mining men.

C. L. N. F.

*Physiology for the Laboratory.* By Bertha Millard Brown, S.B. Pp. viii + 167. (Boston: Ginn and Co., 1900.)

THIS little book sets forth, in twenty-two brief chapters, certain practical directions for the study of the elements of anatomy, histology and physiology of the vertebrate body, and the first principles of bacteriology. Many of the instructions given are in interrogatory form, and for simple experiment and observation of the living in action, in which lies the very essence of the science of physiology, the student is commendably referred to his or her own body. Beyond this, however, there is nothing in the book that is new, or which calls for comment in these pages. The mode of treatment is begotten of a conviction on the part of the authoress, that "there is needed a radical change in the teaching of physiology"; and we read with astonishment the statement that while the method of teaching botany, chemistry and other sciences "has long been that of going first to the study of the specimen and then to the text-book," this has not been the case for "physiology"—that having apparently been taught from the text-book alone. She is writing, however, of State schools of America, and if the accusation be applicable to them generally, we wish her success in her enterprise.

*Michigan Board of Agriculture. Annual Report* 1898-99. Pp. 465. (Michigan: State Board of Agriculture, 1899.)

IN this volume are included the thirty-eighth annual report of the Secretary of the Michigan State Board of Agriculture, and the twelfth annual report of the Experiment Station of the State Agricultural College. Many subjects of interest are dealt with in both reports, but only a few can be referred to here. Experiments with Indian corn, to test the influence of thickness of planting upon the character of the crop, show that a gradual increase occurs in the yield of dry matter and protein as the distance between the rows and between individual plants is increased. It appears that, to obtain the greatest yield of valuable nutrients, Indian corn should be planted in rows fully three and a half feet apart, and the seeds six and nine inches apart in the rows. The establishment of several large beet-sugar factories in the State last year has caused increased attention to be given to experiments in beet culture. An interesting detail of some new experimental work, to which reference is made by Prof. C. D. Smith, director of the Experimental Station, is the breeding of bees with longer tongues. It is hoped that, by selection and breeding, a variety of honey bee will be developed capable of extracting nectar from the blossoms of the clover grown in the State.

Among the subjects of *Bulletins* published in the report are:—forestry, strawberry culture, methods of combating disease-producing germs and fruit-growing.

## *LETTERS TO THE EDITOR.*

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Change of Feeding Habits of Rhinoceros-birds in British East Africa.

THE enclosed extract from a letter just received by me from my friend, Captain Hinde, of the British East Africa Protectorate, will interest all zoologists. It is a curious fact that a bird which is so valuable as Buphaga in clearing parasitic insects from cattle that we lately agreed to give it special protection at the International Conference on the Preservation of African Wild Animals, should now, by a sudden change of conditions induced by man, become a dangerous and noxious creature. This fact shows how difficult is the problem presented by the relations of civilised man to a fauna and flora new to his influence. E. RAY LANKESTER.

Natural History Museum, London, August 10.

"The following case of wild birds changing their habits may interest you:—The common rhinoceros-bird (*Buphaga erythroepyncha*) here formerly fed on ticks and other parasites which infest game and domestic animals; occasionally, if an animal had a sore, the birds would probe the sore to such an extent that it sometimes killed the animal. Since the cattle plague destroyed the immense herds in Ukambani, and nearly all the sheep and goats were eaten during the late famine, the birds, deprived of their food, have become carnivorous, and now any domestic animal not constantly watched is killed by them. Perfectly healthy animals have their ears eaten down to the bone, holes torn in their backs and in the femoral regions. Native boys amuse themselves sometimes by shooting the birds on the cattle with arrows, the points of which are passed through a piece of wood or ivory for about half an inch, so if the animal is struck instead of the bird no harm is done. The few thus killed do not seem in any way to affect the numbers of these pests. On my own animals, when a hole has been dug, I put in iodoform powder, and that particular wound is generally avoided by the birds afterwards; but if the birds attack it again, they become almost immediately comatose and can be destroyed. This remedy is expensive and not very effective. Is there any other drug you could suggest that would be less likely to be detected? Perhaps you know that I reported three years ago that these birds rendered isolation under the cattle plague regulations useless in some districts, as I proved beyond doubt they were the only means of communication between clean and infected herds under supervision, a mile or two apart. These birds I have never seen on the great herds of game on the open plains, but I have seen them on antelope and rhinoceros in the immediate neighbourhood of Masai villages, and herds of cattle; on the other hand, I have never seen the small egret on cattle, though often on rhinoceros and gnū."

### Atmospheric Electricity.

IN NATURE of June 14 Mr. Wilson replies to the objections raised in my letter of March 29 to his explanation of the origin of atmospheric electricity. Before proceeding to consider Mr. Wilson's reply to my objections it may be well that the point at issue between us should be clearly defined, as Mr. Wilson, in my opinion, somewhat confuses it. Mr. Wilson says, "Mr. Aitken contends there is no such thing as dust-free air in the atmosphere." Now I certainly made no such statement, for the simple reason that I do not know whether such a condition exists to any extent or not, only a few cases being on record. What I did state was, "So far as our knowledge goes, it can hardly be said there is such a thing as dust-free air in our atmosphere, and the cases in which low numbers have been observed are so extremely rare that they can hardly have any bearing on phenomena of such widespread existence as atmospheric electricity, even though we suppose those few particles to be afterwards got rid of." I simply asked for a verdict of "not proven" against Mr. Wilson's theory. I think it will be admitted that it rests with Mr. Wilson, and those who think with him, to prove that the air is generally dust-free at elevations higher than ordinary cumulus and nimbus clouds, as without this dustless air the supersaturation necessary for condensation on ions is admittedly not possible.

Mr. Wilson discusses the question of the number of dust particles in the atmosphere from Mr. Rankin's Ben Nevis observations and my own at Kingairloch, and points out that practically dust-free air has been observed on Ben Nevis. Such is the case, but so far as I know dust-free air has been observed on only a few occasions, and such isolated instances have evidently no bearing on the case. Mr. Wilson then turns to my observations and says "the mean number of dust particles in a series of 258 observations, extending over nearly five years, amounting to 338 per c.c.; on one occasion the number was as low as 16 per c.c." The above statement, it must be clearly understood, refers to 258 of the tests made in the purest air, and is not the mean of all the observations. In the tables there are 688 observations for Kingairloch: of these I find there are 41 in which the reading was under 100, 341 were over a 100 but less than 1000 per c.c., whilst the remaining 306 observations were all over 1000 per c.c. The 16 per c.c. referred to by Mr. Wilson only occurred once. In the other years referred to the lowest figures were 38, 43, 67 and 205 per c.c. So that, as already said, the conditions represented by those low figures, such as 0 on Ben Nevis and 16 at Kingairloch, are so exceptional that they are not likely to play any part in phenomena so universal as atmospheric electricity.

Mr. Wilson, referring to the selected observations taken at Kingairloch on the pure air coming from the Atlantic, says: "Air coming from such a region can hardly be considered as abnormal. Moreover, such observations are necessarily made in air within a few feet of the ground; at a greater height it is likely to be less contaminated." Taking the last of these points first, an examination of the diagrams given along with the tables, from which Mr. Wilson made his extracts, will show that whenever the air became pure the readings low down and high up were nearly alike. This is shown by the curves in the diagrams for Ben Nevis and Kingairloch being nearly alike during these periods. Further, it may be seen from the curves that there was sometimes less dust at low than at high level when the air came from the Atlantic.

An examination of the tables from which Mr. Wilson took his Kingairloch figures easily refutes his assumption that the air of the Atlantic, as given in these tables, "can hardly be considered as abnormal." In the tables will be found the results of tests made in France, Italy and Switzerland. Observations were made at three places in France on the shores of the Mediterranean, at Hyères, Cannes and Mentone. An analysis of the figures for these places, made during visits extending over five years, shows that the lowest number observed was 725 per c.c., and of eighty-eight tests only ten were under 1000 per c.c., the others being all over 1000. At the Italian Lakes observations were made at Bellagio and Baveno. Many of these observations were made at elevations up to 2000 feet. In all, 188 tests were made: of these the lowest was 300 per c.c. On only thirteen occasions was the number under 1000, and 175 readings gave numbers over 1000 per c.c.

Perhaps it may be objected that all these Continental tests were made in low level polluted air. We shall therefore now examine the result of the observations made on the Rigi Kulm, given in the same tables. The top of the Rigi is 5900 feet above sea-level, but it has only the purifying effect of 4400 feet, as it is only about that height above the surrounding plains. During the tests, made on the visits during the five different years previously referred to, 259 observations were taken on thirty-two days, and the lowest number observed was 210 per c.c. Ninety-seven observations gave readings under 1000 per c.c., whilst the other 162 tests were all over 1000 per c.c. These tests, at both high and low level, give no support to Mr. Wilson's statement that the Atlantic air on the west coast of Scotland "can hardly be considered as abnormal."

Let me further support this point by reference to observations made by others of the air in different parts of the world. Prof. G. Melander, of Helsingfors, in his work, entitled "Sur la condensation de la vapeur d'eau dans l'atmosphère," gives the results of 268 tests made of the air at Salève, Biskra, Torhola, Loimola, Kristianssund and Grip. In all these 268 samples of air tested there were only five with less than 500 per c.c., and no low numbers were observed.

I now turn to the very interesting series of observations made by Mr. E. D. Fridlander and published in the *Quarterly Journal* of the Royal Meteorological Society, vol. xxii. No. 99, July 1896. In this paper Mr. Fridlander gives the results of his observations made during a voyage round the world from this country to America, across that continent to Santa Cruz Bay, from there across the Pacific Ocean to New Zealand, then to Australia, and homewards by the Indian Ocean, Arabian Sea and Mediterranean, visiting Switzerland on the way. On the western side of the Atlantic the numbers were high, being from 2000 to 4000 per c.c., though the vessel was far from land, its position being 55° 0′ N., 42° 11′ W. Lower numbers were obtained between Labrador and Newfoundland, the readings there being from 420 to 840 per c.c. Readings as low as 280 per c.c. were got in the Gulf of St. Lawrence. On the Pacific coast the lowest was 700 and highest 4500 per c.c. On the Pacific Ocean the lowest reading was 280 per c.c. and highest 2125. Few readings were obtained in New Zealand under 1000 per c.c. In the Indian Ocean the air seems to be rather purer than most places, or at least was so when the observations were made. Readings as low as 200 per c.c. were obtained, and they seldom were over 500. Tests made on only two days in the Arabian Sea gave a minimum of 280 and a maximum of 1375. One day's tests in the Red Sea gave from 383 to 490 per c.c. The result of two days' tests of the Mediterranean air gave a minimum of 875 and a maximum of 2500 per c.c. A result which agrees with that already given for the French coast of the Mediterranean.

Mr. Fridlander's tests of the air in Switzerland give results similar to those already referred to for the Rigi Kulm. At almost all the places the numbers were always over 1000 per c.c., though the observations were made at considerable elevations. But on the Riffelberg (altitude 7400), where Mr. Fridlander spent some days, the numbers varied from 225 to 4000 per c.c. On the summit of the Bieshorn (altitude 13,600) the lowest observation gave 140 per c.c., which, so far as I know, is the lowest number yet observed in Switzerland. When we compare the figures given by Prof. Melander and Mr. Fridlander of the dust particles in the air of different parts of the world with those obtained in the Atlantic air on the west coast of Scotland, we are forced to admit that the latter is abnormally pure.

The rate of fall of cloud particles as given by the calculations of Mr. Wilson seems to be much too rapid. He assumes that the air in which clouds are formed is always rising. This can hardly be said to be the fact. Suppose a large area of the earth's surface to be covered with cloud, forming a vast sea, such as one sometimes sees from the top of a mountain. It is evident that the air over all that area cannot be rising at any considerable rate, and yet the clouds will be seen to keep nearly the same elevation for hours. If the air be still, and if Mr. Wilson's calculations are correct, then the mountains ought to rise out of such a cloudy sea at the rate of nearly 500 feet per hour, a phenomenon which, I venture to say, no one has ever seen.

Mr. Wilson seems to think, though all the dust particles in cloudy air will not become centres of condensation, it is a matter of no importance, as he thinks the cloud will act as a perfect filter, by the descending cloud particles coming in contact with, and absorbing, the inactive dust particles. So that all particles that do not become active centres of condensation will be carried out of the air by the falling drops, and leave the air rising through the cloud particles dustless. He gives no evidence in support of this assumption other than the purification of dusty air in a closed vessel with wet sides. Now dusty air in a closed vessel takes a considerable time to become dust-free, and I think it may be contended that gravitation plays no inconsiderable part in the process, perhaps more than the wet sides referred to by Mr. Wilson. So far as my observations go, there is no evidence of any such powerful purifying effect in clouds. At least when making observations in old clouds, both at top and bottom of them, there were always observed a large number of dust particles, but whether any had been absorbed by the cloud particles or not it would be impossible to say. If any had been absorbed, certainly many were still free.

That clouds have not the purifying effect claimed for them by Mr. Wilson may be best shown by reference to the observations made on the Rigi Kulm on May 21, 1889 (*Proc.* Roy. Soc. Edin., vol. xvii. p. 193). On the morning of that day, when I left Lucerne on my way to the Rigi Kulm, the sky was covered with cloud, and when ascending the mountain the cloud was entered at an elevation of about 2000 feet below the top. On arriving at the top the clouds were still very dense, and remained so till the evening; afterwards they settled down to the level of the kulm, when a vast sea of clouds was disclosed stretching in all directions with the peaks of the higher Alps standing out like islands. Under these conditions the observations made on the top of the Rigi on that day were evidently taken in air just above the upper surface of a uniform stratum of cloud 2000 feet deep, where, according to Mr. Wilson, there ought to have been dustless air, yet the observations showed there were still 210 particles per c.c. Next morning the clouds still extended in most directions and were much thinner, and the number of dust particles had increased to over 800.

I may as a well here call attention to the fact that during the night the upper surface of the clouds had only settled down about 1000 feet. How much of this was due to the cloud particles falling through the air, and how much to evaporation, it would be hard to say. Probably evaporation played the principal part, as the clouds were now much thinner, and the evaporation probably took place from the upper surface, as in the morning the air on the Kulm was dry—the wet-bulb depression being as much as 6°, and a wind of some strength was blowing from the south-east. The rate of descent of the particles in this cloud was therefore much slower than the rate of fall calculated by Mr. Wilson.

Mr. Wilson, in criticising my remarks on the re-evaporation of cloud particles, says: "But all drops that have survived the great tendency to evaporate which accompanies the initial stages of their growth will surely continue to grow so long as the rate of expansion remains the same, or even if it be much reduced." Here again Mr. Wilson assumes that clouds are always rising. Now a great part of the life of a cloud, and the air in which the particles are carried, is spent in moving horizontally, and sometimes even downwards, and occasionally with but little movement in any direction; and it is during this stable condition that the opportunity is given for the re-evaporation of the smaller drops. Mr. Wilson points out that if a very slight proportion of the water in a drop were to evaporate, it would cool the drop and check the evaporation, a statement with which all will agree. But though the cooling may check evaporation, it will not stop it. The particles in a cloud are close together, and those condensing vapour and growing warmer soon part with their heat by radiation and by contact with the air, so that the heat lost by the evaporating particles is rapidly supplied to them by the condensing ones, and, as we shall see later, this exchange of heat takes place at a much quicker rate than one might imagine.

I do not think that practical chemists will agree with Mr. Wilson's statement that all the ammonia, nitric acid and other impurities, out of which the sun can manufacture nuclei, will be washed out of the air by the rain. The difficulty of removing the last traces of gases by washing is well known.

Are meteorologists prepared to accept that part of Mr. Wilson's theory which necessitates the formation of rain-clouds at an elevation of 7500 feet above the top of the ordinary cumulus and nimbus clouds? In other words, are meteorologists prepared to affirm that there are two distinct rain zones—one where the ordinary rain-clouds condensed on dust nuclei are formed, then over these clouds clear air for 7500 feet, above which the ion rain-clouds are formed? This upper ion-cloud must result in rain if the theory is correct, otherwise there will be no separation of the positive and negative ions. I leave it to the meteorologists to say whether rain-clouds have ever been observed at elevations of 20,000 to 30,000 feet—not above sea-level, but above the surface of the ground.

Mr. Wilson does not seem to think that my remarks on the rapid growth of cloud particles in supersaturated air have any bearing on the subject, and objects to my use of the term explosive in reference to the condition of supersaturated air. If I had known a better term I would have used it. Though supersaturated air is in a condition of equilibrium with itself, yet when nuclei are introduced into it there is at once a rapid rush of vapour molecules towards the condensing particles, and a rapid breakdown of conditions all round the nuclei, which seems to me not at all inaptly compared to an explosion—centripetally, of course. Mr. Wilson grounds his objection to the rapid growth of the ion-cloud particles in supersaturated air on the difficulty and slowness with which the condensing drops part with the heat developed by the condensing vapour. I shall not follow Mr. Wilson in his comparison of a condensing with an evaporating drop, as it is not easy to see the changes taking place in the latter, but will rather refer to an experiment which Mr. Wilson, and others who have experimented on this subject, must often have seen. Take a glass flask in which there is a little water, full of ordinary air, and provided with means of expanding the air in the flask, and either returning the air to the flask, or admitting filtered air. Go on repeating the process of expanding and cloud-making in the flask. After this has been done a number of times, the nuclei become fewer and fewer, and at last only a very few are left in the air. Every one must have noticed when making this experiment that the cloud particles are very small on the first expansion, and that they fall very slowly, almost imperceptibly, but that at the end of the experiment, when the last dust particles become nuclei, the water particles are large and fall rapidly like rain drops. At the beginning of the experiment, with plenty of dust in the air, there is almost no supersaturation, the nuclei being so close the tension is relieved as soon as it is formed. When, however, only a few particles are present, there are large spaces between the nuclei where supersaturation can take place, and it is by falling through this supersaturated air that the drops, when few in number, are able to grow so quickly and become so large. It therefore seems probable that something of the same kind will happen if ions were to become nuclei in supersaturated air. Whenever an ion becomes active it will rapidly grow to the dimensions of a rain-drop in the same manner and for the same reason that the dust-nucleused drops do in supersaturated air. These little drops evidently have a way of parting with the heat of condensation at a very much quicker rate than Mr. Wilson is disposed to admit.

It is this capacity for rapid growth in supersaturated air that makes it so improbable that ions can ever give rise to a cloudy form of condensation. To form a cloud a large number of them would require to become active at the same moment. But this is evidently not possible in a rising column of air. The ions which rise on the top of the ascending column will become active first, and by falling through the lower supersaturated air will grow with great rapidity and give rise to a rainy, but cloudless form of condensation.

There are some points connected with ions about which I think the readers of NATURE would be glad to have some information, and which I think Mr. Wilson, with the aid of the apparatus at his disposal, could give us. For instance, one would like to know (1) how long ions remain in air in an inclosed vessel, when both + and − ions are present; (2) when only + or − ions are in the air; (3) whether the presence of dust has any effect on the duration of their life. For practical purposes one would also like to know further (1) how many ions are generally in the air near the ground; (2) what amount of electricity they carry with them.

Finally, one would like to know how many ions will pass up through a cloud and escape at the top; as one would almost expect, these ions, with their electric charges, will be more likely to be cleared out of the air by rain than the dust particles, and whether both kinds are equally liable to be washed out by rain. If not, the inequality may help to explain some important electrical phenomena.

JOHN AITKEN.

Ardenlea, Falkirk, June 27.

### The Melting Points of Rock-forming Minerals.

IN connection with the abstracts of papers read before the Royal Dublin Society by Dr. J. Joly, F.R.S., and myself, given in NATURE for July 12 (p. 262), I might perhaps be permitted to draw attention to a few points. The same subject has been recently dealt with by Mr. C. E. Stromeyer (*Mem.* Manchester Lit. and Phil. Soc., vol. xliv. Part iii. No. 7, 1900) and by Prof. Sollas, F.R.S. (*Geol. Mag.*, July 1900).

In the first place it may be noted that the "melting point" of a substance under a definite pressure has a perfectly definite meaning. The "softening point," on the other hand, obviously depends on the magnitude of the distorting force with which the softness is tested, as well as on the other conditions of experiment.

It is an established fact that the melting points of a very large number of substances vary with the pressure. Bunsen, as far back as 1850, perceived the geological application of this phenomenon. In discussing the crystallisation of plutonic rocks, it is the melting points of the minerals under enormous pressures which really concern us. These pressures are probably sufficient to alter the melting points through several hundred degrees. There are then two ways open for us to ascertain these melting points. Firstly, we might determine them by direct experiment at the necessary large pressures; or, secondly, we might measure the melting points at ordinary atmospheric pressure and determine the rate of increase (or decrease) of melting point with increase of pressure ($d\theta/dp$). Considering the gigantic pressures with which we have to deal, it seems decidedly easier to adopt the second method. The agreement between the results obtained from the application of the thermodynamic formula

$$\frac{d\theta}{dp}=\frac{\theta(v_l-v_s)}{L}$$

(where $\theta$ = absolute melting temperature; $(v_l-v_s)$ = the change of volume at the instant of melting; L = the latent heat in mechanical units) with the results of experiments (*e.g.* M. A. Battelli, *Journal de Phys.*, t. viii. p. 90, 1887), seems to justify the application of that formula to the case of the minerals in question, in the absence of direct experiment. It is true that the formula was deduced for a reversible system, and that no natural process is reversible. But a similar objection would hold against the application of any theoretical formula to the conditions obtainable in experimental work. In the present case it is only claimed for the formula that it will afford an approximate estimate of the melting points of minerals under large pressures; and after all, even direct measurement of such high temperatures as are involved is always attended with uncertainty. In order to apply this formula we require $\theta$, $(v_l-v_s)$, and L. The melting points of the most important minerals at atmospheric pressure have been determined by Dr. Joly and Mr. R. Cusack (*Proc.* Roy. Irish Acad., Ser. 3. vol. ii. p. 38; vol. iv. p. 399). A large part of the volume change on melting is, I submit, afforded us by the difference in density between the crystalline mineral and its fused glass. Now it is characteristic of amorphous substances to pass gradually and continuously from solid to liquid (*cf.* Preston, "Theory of Heat," pp. 270 and 286); and so it is highly probable that such a mineral glass will pass without sudden volume change into the liquid state, and it has, in fact, passed gradually in the inverse direction. It is not contended that any given mineral ever existed as a glass in the molten magma of an igneous rock, but only that it existed as a liquid.

In my paper, above referred to, I have shown how the "fusibility" of a mineral must be connected with its latent heat, and hence by a comparison of relative fusibility and melting temperature we may often deduce the relative latent heats of two minerals. Thus, for example, the "fusibility" of labradorite is 3 on von Kobell's scale, and its melting point is 1229° C., whereas orthoclase has a melting point of only 1175° C., but is much less "fusible," viz. 5 on von Kobell's scale. Hence I infer that the latent heat of orthoclase is decidedly greater than that of labradorite. Similarly, the latent heat of augite is less than that of orthoclase. But the volume-change on melting of augite is greater than that of orthoclase. Therefore $d\theta/dp$ is greater for augite than for orthoclase. It is thus possible to arrive at the order of melting points of minerals under the pressure of rock formation. If, after ascertaining this order, it is still found to be inconsistent with the order of crystallisation, as shown by microsopical examination, it may be necessary to examine the more complicated influences of solution, &c., on the crystallising points of the minerals.

In conclusion, I may point out that it must be a matter of extreme importance in measuring the melting temperature of quartz to make sure that the specimen used is pure, and in particular free from the alkalis. Messrs. Shenstone and Lacell (NATURE, May 3, 1900, p. 20) have found that rock crystal very often contains sodium and lithium, traces of which might be expected to lower the melting point. Further, it has long been known that quartz, with a density of 2·66, passes into the variety of silica with density 2·3 at a temperature below its melting point (*cf.* Fremy, *Enc. Chim.* 6, p. 142). And similar transformations are common among metals. Is it not possible then that the phenomena observed by Dr. Joly may have nothing to do with the fusion point of quartz, but are simply cases of molecular transformation at a temperature below the melting point?

J. A. CUNNINGHAM.

Royal College of Science, Dublin.

### Observation of the Circular Components in the "Faraday Effect."

AFTER repeated attempts to determine the nature of the "Faraday effect," I have succeeded in observing that ordinary light, when passing from a surface into a medium in such a way as to be under the influence of a magnetic field, is broken up into two circular components oppositely polarised.

The system used consisted of two rectangular prisms of glass placed with their diagonal faces parallel and separated by a plate of mica of approximately ¼ $\lambda$ retardation. The lines of force were parallel to this plate. A ray of ordinary light from a sodium flame sent into the system normal to this plate was successively totally reflected parallel to the lines of force and then at right angles to the mica, which served to change the phase and to keep the absolute direction of the circular vibrations the same. The rays passed five times around within this system, giving twenty internal reflections.

The separation of the rays agreed, so far as could be determined, with the calculations based on the assumptions usually made in explaining this phenomenon. When the field was reversed, the direction of vibration of each circular component was reversed. This does not establish the assumption of a relative change in the velocities usually made, as a relative change in the phase of the components, or both, would produce the same effect. It does show, however, that a medium in a magnetic field transmits, in the direction of the lines of force, light vibrations by circular components only. D. B. BRACE.

Physical Laboratory, University of Nebraska, August 1.

### Physical Structure of Asbestos.

CAN any of your readers tell me where I can find a good account of asbestos and its *physical structure?* The ordinary works of reference I am acquainted with give too meagre an account to be of any use. GEOFFREY MARTIN.

13 Hampton Road, Bristol, August 1.

---

## *THE BRADFORD MEETING OF THE BRITISH ASSOCIATION.*

IT is now possible to give a forecast of the chief subjects to be brought before the various Sections of the British Association at the forthcoming Bradford meeting. The following outlines of sectional programmes show that many matters of importance and wide scientific interest will be dealt with, so that the Bradford meeting promises to be a memorable one. No particulars as to the probable proceedings of the Physics Section have yet been received.

### CHEMISTRY.

Prof. W. H. Perkin, jun., F.R.S., the President of Section B (Chemistry) is this year setting a precedent in the conduct of the sectional meetings. Several members of the Association have been asked to furnish reports on the present state of knowledge in the particular departments of chemistry with which they are especially conversant, and the reading of these reports will be followed by discussion.

In accordance with this programme, Mr. Francis H. Neville, F.R.S., will present a report dealing with the properties and interactions of the metals. The following questions will be brought forward for discussion in connection with the report :—

1. Are the methods usually employed in studying the equilibrium between two or more substances with change of temperature immediately applicable to the study of alloys, and are similar results obtained in the two cases? Thus, with varying conditions of temperature and concentration, a system of ferric chloride and water deposits (1) ice; (2) $Fe_2Cl_6,12H_2O$; (3) $Fe_2Cl_6,7H_2O$; (4) $Fe_2Cl_6,5H_2O$; (5) $Fe_2Cl_6, 4H_2O$; (6) $Fe_2Cl_6$ or (7) mixtures of the phase numbered $n$ with that numbered $(n+1)$? Are the solubility curve of ferric chloride and the freezing point curves of metallic mixtures of the same kind?

2. How far does (1) microscopic examination, and (2) change in physical properties, such as electromotive force, &c., enable us to detect the existence of a compound in an alloy?

3. In what definite proportions are metals known to combine? Is any regularity manifest with respect either to their position in the periodic system or to their valency with regard to non-metals?

4. What methods are available for determining the molecular weights of the metals, and can it be asserted in any cases, other than those of mercury, zinc and cadmium, that the molecular weight is satisfactorily determined?

5. Can a definition be given of a metallic element which makes it possible to distinguish between metals and non-metals?

6. Can any explanation be given which will satisfactorily account for (1) the difference between metallic and electrolytic conduction, and (2) the remarkable changes in the electrical conductivity of metals attending admixture?

As some of the questions bearing upon this subject are of as great importance to the physicist as to the chemist, physical members of the Association are to be invited to join in the discussion. Dr. Adolf Liebmann will contribute a report on recent improvements in the treatment of textiles, a subject which acquires peculiar importance from the fact that the 1900 Meeting of the Association is being held in the centre of a district devoted to the textile industry. Dr. Arthur Lapworth will give a report on our knowledge of the chemistry and constitution of camphor. Attention has of late years become so concentrated on the chemistry of the camphor group as to make an authoritative discussion on the constitution of camphor almost a necessity to the organic chemist. Mr. William J. Pope will present a report on our present knowledge of stereochemistry; it is understood that special attention will be given in this report to the work done during the past twelve months on the optical activity of compounds containing an asymmetric nitrogen, tin or sulphur atom. Among the other papers to be presented at the meeting is one on the specific heat of gases at temperatures above 400°, by Prof. H. B. Dixon, F.R.S.; and Mr. H. T. Brown, F.R.S., will give an account of his recent work on the diffusion of gases and liquids. The papers of special local interest include one on the treatment of Bradford sewage, by Mr. F. W. Richardson, the City analyst; and also a paper on the treatment of woolcombers' effluents, by Mr. W. Leach. The title of the sectional address to be delivered by the President is, of course, not yet announced; it is understood, however, that the address will deal with the teaching of chemistry.

### GEOLOGY.

The proceedings of Section C (Geology) will open at 10.30 a.m. on Thursday, September 6, with the delivery of the address of its president, Prof. W. J. Sollas, who has chosen for his subject, "The History of the Earth in relation to a Scale of Time." Prof. Sollas will take a wide scope in discussing this subject, and will introduce such fundamental matters as the constitution of the earth, the relative value of the various geological periods, the origin of ocean basins, the formation of mountain-chains, and the evolution of the organic world. We may be sure that his discourse will be brilliant and suggestive. It is probable that Prof. J. Joly will also treat on the knotty problem of the duration of geological time at the same, or a subsequent, meeting of the Section.

As befits the place of meeting, the geology of the Carboniferous rocks will receive much attention. A joint discussion with the botanists (Section K), on the conditions which existed during the growth of the forests of the Coal Period, will be held on Monday, September 10, when Mr. A. Strahan and Mr. J. E. Marr will open the debate from the geologist's standpoint. The Coal-measures of the West Riding form the subject of a paper by Mr. W. Cash, and those of North Staffordshire of one by Mr. W. Gibson, of H.M. Geological Survey; while the fossil fishes of the Carboniferous rocks will be discussed by Dr. E. D. Wellburn. Prof. W. B. Scott has promised a paper, with lantern illustrations, on the geology and palæontology of Patagonia, which promises to be of great interest. Prof. A. P. Coleman, of Toronto, brings forward an account of a ferriferous horizon in the Huronian of Lake Superior, and will also present the final report of the Committee for the investigation of Pleistocene deposits in Canada. Mr. J. J. H. Teall will describe a plutonic complex of Sutherland, and its bearing on current hypotheses as to the genesis of igneous rocks. Glacial subjects, as usual, will receive due attention; papers on the local phenomena will be brought forward by Dr. Monckman and Messrs. Muff, Jowett and others, and on those of Welsh localities by Mr. E. Greenley and Mr. J. R. Dakyns. The concretions of the magnesium limestone of Durham will be discussed by Dr. Abbott. Tidal ripple-marks will be described by Mr. Vaughan Cornish; and the caves and pot-holes of Ingleborough and district by their explorer, Mr. S. W. Cuttriss, in both cases with lantern illustrations. Mr. A. C. Seward will treat of the Jurassic flora of the Yorkshire coast. Among the reports of committees will be that which deals with the course taken by underground waters in the Ingleborough district, giving the result of recent experiments; and excursions have been arranged to the sites of the investigation. As usual, short afternoon sectional excursions to places of geological interest in the neighbourhood of Bradford will be included in the arrangements of the Section.

### ZOOLOGY (AND PHYSIOLOGY).

Dr. R. H. Traquair, F.R.S., the President of Section D (Zoology and Physiology), will address the Section on "The Bearings of Fossil Ichthyology on the Doctrine of Descent." Major Ronald Ross will (by request) address the Section on "Malaria and Mosquitoes." Messrs. Gamble and Keeble will give an account of their researches on the "Colour-Physiology of Hippolyte," illustrated by lantern projections and practical demonstrations. Prof. L. C. Miall, F.R.S., will read a paper on the "Respiration of Aquatic Insects"; and other papers on the natural history of insects will be given by Messrs. T. H. Taylor, Wilkinson, Walker, and Dr. Munro. Prof. S. J. Hickson, F.R.S., will read a paper on "The Nuclei of Dendrocometes." Among the reports of committees, Mr. Stanley Gardiner's account of his researches on the Coral Islands of the Indian Ocean is awaited with particular interest.

### GEOGRAPHY.

In Section E (Geography), the President, Sir George Robertson, will deliver his address on Thursday, September 6, at 11 a.m. The subject of the address is appropriately "Geography and the Empire." Amongst the subjects to which special attention will be directed in the Section may be mentioned that of "Colonial and Foreign Surveys." Papers dealing with these will be read by Mr. E. G. Ravenstein and Mr. B. V. Darbishire; and Dr. H. R. Mill will contribute a paper on "The Treatment of Regional Geography." Problems of applied commercial geography will be dealt with by Mr. G. G. Chisholm in a paper on "Some Consequences that may be Anticipated from the Development of the Resources of China," and Mr. E. Heawood on the "Commercial Resources of Africa."

An important paper on "Railway connection between Europe and Asia" will be contributed by Sir Thomas Holdich; and it is hoped that Mr. C. R. Beazeley will return in time to give an account of his journeys on the recently-opened portions of the Siberian Railway.

The excellent work initiated by Mr. T. G. Rooper while H.M. Inspector of Schools at Bradford, and carried on by Mr. E. R. Wethey, one of the secretaries of the Section, makes papers on "School Geography," and the teaching of elementary geography generally, of special interest at this meeting. Mr. Rooper and Mr. Wethey will each describe parts of their work, and will exhibit some of the maps and models used as illustrations, in the exhibition which forms a novel feature of the Bradford meeting.

In the department of geographical exploration, Mr. C. E. Borchgrevink will give an account of the voyage of the *Southern Cross* in the Antarctic regions. Captain H. P. Deasy will describe his journeys in Central Asia; Captain E. S. Grogan contributes a paper, "Through Africa from the Cape to Cairo"; and Mr. Cutliffe Hyne one on "Arctic Lapland."

On special and more technical subjects there will be papers on "Large Earthquakes in 1899," by Prof. John Milne; on the "Distribution of Relative Humidity," by Mr. E. G. Ravenstein; on "Snow Ripples," by Mr. Vaughan Cornish; and on "The Origin of Moels," by Mr. J. E. Marr.

### MECHANICAL SCIENCE.

Sir Alexander Binnie, the President of Section G (Mechanical Science), will survey the various stages of scientific progress which have led to the modern conception of natural phenomena. Several interesting papers by local engineers will be read before the Section. One, by Mr. J. Watson, will describe the Bradford waterworks and the very fine reservoirs belonging to that system. In connection with this there will be an excursion on the Saturday to the reservoirs. A paper will be read by Prof. Hele-Shaw on the resistance of road vehicles to traction. A proposal will be made to appoint a committee of the Association to carry out an exhaustive series of experiments on road resistance. Much interest will no doubt be excited by the paper which is to be read by Mr. J. H. Glass on the coal and iron ore fields at Shansi and Honan, and railway construction in China. This paper will be illustrated by a number of lantern slides showing the Chinese methods of working these mineral deposits. In view of the great industry of Bradford, the paper by Prof. Beaumont on the application of photography to textile designing is likely to create great interest. In the department of electrical engineering there is a good programme of papers. The Small Screw Gauge Committee will submit a report descriptive of a series of experiments which have been carried out by Mr. Price in the engineering laboratory at University College, London; and in connection with this, a paper will be read by Mr. O. P. Clements on screw threads used in cycle construction and for screws subject to vibration. Mr. A. Mallock will give an account of experiments he has made to determine the tractive force, resistance, and acceleration of electric trains. Mr. Aldridge's paper on the automobile for electric street traction will describe a novel process, by means of which, in certain circumstances, it is possible to organise a tram service without tram rails, and this paper will be illustrated by the cinematograph, showing an actual system at work.

### ANTHROPOLOGY.

In the Anthropological Section, the President, Prof. J. Rhys, proposes to devote his opening address to "the prehistoric ethnology of the British Isles," a subject full of matter for discussion, on which he is entitled to speak with peculiar authority. Several important papers are expected in the department of anthropometry, especially a note by Dr. Beddoe on the "vagaries of the Cephalic Index," and a paper by Prof. Cunningham on the "Sacral Index." Mr. H. Ling Roth contributes a classification of various modes of ornamenting the skin, such as tattooing, cicatrisation, and the like. Dr. Haddon promises an account of his recent visit to Borneo, with special reference to the industries and daily life of the natives. A discussion is being arranged on the subject of "Animal Worships," with reference to the vexed question of the significance of totemism; and Mr. David Boyle, of Toronto, will contribute a study of the phenomena of Neo-Paganism among the natives of certain parts of the Dominion of Canada. Among other archæological papers, special interest attaches to Mr. Arthur Evans's account of his recent discovery of tablets inscribed with an Ægean script, in the Mycenæan palace of Gnossus in Crete; and to Mr. F. Ll. Griffith's discussion of the origin of the Egyptian hieroglyphic system. There will be papers, as usual, on objects of archæological interest in the neighbourhood of Bradford.

### BOTANY.

Prof. Vines, the President of Section K (Botany), in his address on Thursday, September 6, will take as his subject the progress of botany in the nineteenth century. It has been arranged to hold a joint discussion with some of the members of the Geological Section on the conditions under which the forests of the Coal Period grew. The origin and manner of formation of Coal, the climatic and physical conditions which prevailed during the deposition of the Coal-measures, the most striking characteristics of the vegetation, and other questions will probably be dealt with. The local committee propose to form a small museum of specimens and photographs to illustrate the botany and geology of the Coal Period.

On Friday afternoon a semi-popular lecture, illustrated by lantern slides, will be delivered by Mr. Percy Groom, on "Plant-form in relation to nutrition."

Among the papers already promised, the following may be mentioned:—On the presence of seed-like organs in certain Palæozoic Lycopods, by Dr. D. H. Scott; the origin of modern Cycads, by Mr. Worsdell; the fertilisation of *Caltha palustris*, by Miss Thomas; on a new type of transition from stem to root in seedlings, by Miss Sargant; the anatomy of the stem of *Angiopteris evecta*, by Miss Shove; the structure of the nucleolus, also a demonstration of the structure of the eye-spot and flagellum of *Euglena*, by Mr. Wager; the biology and cytology of a new species of *Pythium*, by Dr. Trow; the biology of *Acrospeira mirabilis*, by Mr. Biffen; the histology and reproduction of the Laminariaceæ, and additional notes on the cytology of the reproductive cells in the Dictyotaceæ and Fucaceæ, by Mr. J. Lloyd Williams; on the effect of salts on the $CO_2$ assimilation of *Ulva latissima*, by Mr. Arber; on fungi found on the scale-insects of Ceylon, by Mr. Parkin; the structure and affinities of *Dipteris conjugata*, with notes on the geological history of the Dipteridinæ, by Mr. Seward and Miss Dale.

## *RECORDING TELEPHONES.*

NOW that the telephone has become, even in this country, an instrument of such universal commercial and general employment, the advantages of an apparatus that will satisfactorily record the messages transmitted through an ordinary telephone line are so strikingly apparent that it is unnecessary to enlarge upon them. That it should have been possible to construct such an apparatus has been evident since the invention of the phonograph. But the direct combination of the phonograph with the telephone, which seems so simple in theory, has presented difficulties in practice which up to the present have not been successfully overcome, and the phonograph of to-day, over twenty years since its invention, remains little more than a scientific toy, whereas its contemporary, the telephone, has become an almost indispensable adjunct of civilisation. It would appear, however, that the problem of recording telephone messages is nearing a practical solution, for there have been quite recently put forward, under the names respectively of the "Telephonograph" and the "Telegraphone," two separate inventions of a recording telephone.

The first of these instruments—the "Telephonograph"—is the invention of Mr. E. O. Kumberg, and contains little that is novel in principle, being simply a combination of the phonograph with a loud-speaking telephone receiver, in which the inventor has sought by a suitable design of apparatus to diminish the distortion of voice which is usual with such an arrangement. The invention consists of a phonograph in which a loud-speaking telephone receiver is substituted in place of the ordinary diaphragm to which one speaks. The telephonic currents varying in the receiver set up vibrations in a soft iron diaphragm which is attached by a short stiff wire at its centre to a second diaphragm of mica. The centre of this mica diaphragm is connected by a link with the cutting style, which accordingly traces on the wax cylinder of the phonograph a record of the message transmitted through the telephone. The cylinder can then be subsequently used in connection with the speaking diaphragm of the phonograph to repeat the recorded message. Unfortunately, neither the telephone nor the phonograph is free from distortion, and the "Telephonograph" may be expected to possess in an enhanced degree the imperfection of each of its components; from what we learn, it seems that Mr. Kumberg's invention is by no means perfect in articulation.

The second instrument which has been brought forward under the name of the "Telegraphone" is, we believe, entirely new in its principle, and if it realises but a part of what is claimed for it by its inventor represents a very great advance in telephony. This instrument is the invention of Herr Valdemar Poulsen, a Danish electrician, and is on view at the Paris Exhibition. It is briefly described in a note contributed by Herr Poulsen to the *Comptes rendus* for June 25, and somewhat more fully in an article which appears in the *Revue Générale des Sciences* for June 30.

It is, of course, perfectly well known that if a piece of steel be placed between the poles of an electromagnet which is excited by a current, a magnetic field is set up in the steel, the strength and direction of which depend upon the strength and direction of the current in the exciting coils of the electromagnet, and the magnetism thus induced in the steel is still retained by it when removed from the inducing magnetic field. This is the principle which Herr Poulsen has utilised in the construction of his new recording telephone. In place of the ordinary telephone receiver he uses a simple electromagnet, the current transmitted through the telephone line passing round the exciting coils of the magnet. When, therefore, any one speaks into the transmitting instrument at the far end of the telephone line, the magnetic field due to the electromagnet will vary in strength and direction in accordance with the varying electric currents transmitted through the lines. Between the poles of the magnet is passed a steel wire or band, which is moved forward in the direction of its length at a uniform and rapid velocity. At each point of this wire there will be produced a magnetisation proportional to the current which was flowing through the coils of the electromagnet at the moment when that section of the wire was passing between its poles. There will thus be established in the steel wire a magnetic record of the telephonic message, and just as the varying electric currents have been utilised to produce in the wire a magnetisation varying from point to point along its length, so, by the converse process, may this magnetisation be employed to set up currents in a telephone receiver, and thus reproduce the original speech. It is only necessary to connect the coils of the electromagnet in series with a receiving telephone, and to cause the steel wire on which the magnetic record has been made to pass once again at the same speed and in the same direction between the poles of the magnet; for the variation of the magnetic field which the wire produces as it moves along will generate currents proportional to the rate of variation of this field, and the telephone will respond in the same way, and with the same degree of accuracy, as did the receiving telephone in the early Bell combination of a pair of magneto-telephones prior to the employment of a microphone and a battery.

The diagrams in Figs. 1 and 2 show the arrangement of the apparatus. C is the electromagnet on which are the bobbins of wire B and B′, which are connected either to the transmitting or receiving instrument according as it is desired to record a message or to listen to one already recorded. Between the poles P and P′ of the electromagnet passes the steel wire F, which is wound in a helix over two drums, T and T′, to which the ends of it are attached and which are driven by an electric motor, so that the wire winds off one drum on to the other. The drums rotate at such a speed as to give the wire a linear velocity between the poles of a metre per second. At the same time the magnet C is moved at right angles to the direction of motion of the wire, so that for one revolution of the drums the magnet moves a distance equal to the pitch of the helix.

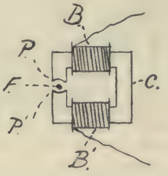

FIG. 1.

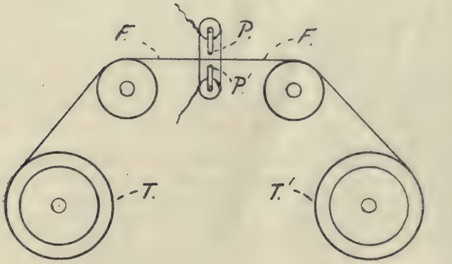

FIG. 2.

The message thus recorded can be effaced, according to Herr Poulsen, by the simple process of passing the steel wire between the poles of the magnet when the latter is excited by a steady current from a battery. This operation establishes in the wire a uniform magnetic field at right angles to its length, and this field, so far from interfering with recording a future message, appears to be necessary before any such record can be made. But if it be desired to keep the record, this may be done instead, and the wire used over and over again to repeat the same message. A thousand repetitions can be made, it is said, without any diminution in loudness or distinctness.

If the recorded message is not sufficiently loud, it is possible with a comparatively simple arrangement to greatly increase its loudness. For this purpose it is necessary to arrange a series of parallel steel wires or bands as shown in Fig. 3, all of which have been previously prepared for receiving a magnetic record by being passed between the poles of a magnet excited by a steady current. The wires are moved at a uniform rate. The first wire, 1, passes first between the poles of an electromagnet M, which is connected to the telephone line, and consequently receives a magnetic record of the transmitted message. The wire next passes between the poles of a second electromagnet, A, which is connected in series with a similar magnet A′, between the poles of which the second wire, 2, passes. As the wire 1 passes between the poles of the magnet A currents are induced in the coils of this magnet, which, traversing also the coils of the companion magnet A′, produce a magnetic record in the wire 2. A similar action occurs as the first wire passes between the poles of the magnets B, C, . . . Z, which are connected in series with the magnets B′, C′, Z′, so that there is established in each of the wires 2, 3, 4, . . . *n*, similar magnetic records. The wires 2, 3, 4, . . . *n* pass finally between the poles of a number of electromagnets, $\Omega_2$, $\Omega_3$, $\Omega_4$, . . . $\Omega_n$, which are all joined in series with a telephone receiver, T. If the two magnets which are joined together in series, such as A, A′, B, B′, . . . are arranged in the same perpendicular to the direction of the steel wires, and if all the wires are moved forward with the same velocity, then the magnetisations in the various wires—2, 3, 4, . . . *n*—at points lying in the same perpendicular will be similar; and since all these points will pass at the same instant between the poles of the magnets $\Omega_2$, $\Omega_3$, $\Omega_4$, . . . $\Omega_n$, they will there superpose their effects, and the intensity of the sound in the telephone, T, will be increased in proportion to the number of wires. It seems possible, therefore, with this device to indefinitely increase the loudness of the received message, and with quite a simple arrangement to easily double or treble the intensity of the sound.

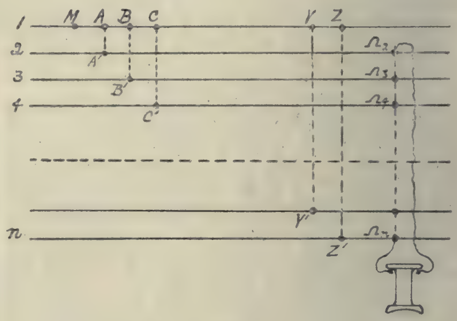

FIG. 3.

There is a second ingenious method by which it is suggested that an increase in loudness can be obtained. In this advantage is taken of the fact, already pointed out, that the strength of the currents induced in the coils of the receiving electromagnet depends on the rate of variation of the magnetic field: it is therefore possible to increase the strength of the currents induced by a field altering from one given strength to another by diminishing the time in which such alteration occurs. If, therefore, we have a steel band on which a magnetic record has been made, we may increase the strength of the currents it will induce in the electromagnet connected to the receiving telephone—and consequently the loudness of the repeated message—by simply increasing the speed at which the band passes between the poles of that electromagnet. But in order to obtain the amplification of the sound in this manner, it is apparent that the band must be moved more quickly when used to repeat the message than it was when used to record it, and thus the increased loudness will be accompanied by an increased quickness, and probably at a sacrifice of clearness due to the alteration in pitch. For if the speed of the band when used for recording be increased, the effect will be merely to spread out the message along the wire, as the intensity of the magnetisation set up in the wire depends only on the strength of the currents transmitted through the telephone, and this strength is determined by the loudness and quickness with which the message is spoken at the transmitting end

The invention of Herr Poulsen may be looked upon as the invention of a magnetic phonograph, and must be regarded as an extremely ingenious and beautiful attempt at the solution of the problem of recording telephonic messages. It possesses many advantages over the combination of the telephone and the wax-cylinder phonograph, especially in the fact that the recording is effected by the immaterial agency of magnetism, and not by the mechanical agency of a style writing on wax, so that the imperfections in the articulation due to mechanical causes should be entirely absent. The method of increasing the loudness by the use of a number of parallel bands appears exceedingly simple, and offers a possible means of making a telephonic relay, and thereby increasing the limits of distance to which sound can be transmitted; it is a method which might be imitated with the ordinary phonograph, by causing the message recorded on the wax cylinder to be repeated to one or more other cylinders, and finally making all repeat their records simultaneously; but in this case the practical difficulties would be very much greater. That Herr Poulsen's invention is still only in an experimental stage may be gathered from the fact that though the instrument itself is on view at Paris, it has been found too difficult at the Exhibition to make the necessary adjustments to exhibit it in operation publicly; but we await with interest its further development, for the introduction of a trustworthy recording telephone would be a benefit to the public, for which it is to be hoped they will not have long to wait.

---

## *NOTES.*

THE French Minister of War has invited the Paris Academy of Sciences to advise as to the precautions to be adopted in selecting and planting trees in the neighbourhood of powder magazines, in order to secure the best protection from lightning.

THE Chancellor of the German Empire has issued an ordinance to the effect that the Réaumur thermometer will not be admitted to official control after January 1, 1901. This will lead to the exclusive use of the centigrade thermometer in Germany.

THE International Congress of Physics, held in Paris last week, appears to have been a complete success, more than a thousand members, including leading physicists of many nationalities, having been obtained. Lord Kelvin received a grand ovation at the opening meeting, and was nominated honorary president of the Congress.

M. OUSTALET and M. Depousarques are the two candidates who have been nominated by the Paris Academy of Sciences for the chair of zoology in the Muséum d'Histoire naturelle, rendered vacant by the death of Prof. Milne-Edwards. The appointment rests with the Minister of Public Instruction.

THE *Athenaeum* announces that Prof. Virchow has been elected an honorary member of the Mathematical and Natural Science Section of the Vienna Akademie der Wissenschaften, while Prof. Klein, of Göttingen, has been appointed corresponding member of the same section.

THE attention of persons interested in zoological gardens and keeping captive animals should be directed to the passing of the "Act for the Prevention of Cruelty to Wild Animals" (63 and 64 Vict., Ch. 33), which has just become law. This Act extends the provisions of the "Cruelty to Animals Acts 1849 and 1854" (which related to domestic animals only) to all birds, fishes and reptiles not included in that Act. By Sect. 2 of the new Act, "Any person shall be guilty of an offence who, whilst an animal is in captivity or close confinement, or is maimed, pinioned, or subjected to any appliance or contrivance for the purpose of hindering or preventing its escape from such captivity or confinement, shall, by wantonly or unreasonably doing or omitting any act, cause or permit to be caused any unnecessary suffering to such animal; or cruelly abuse, infuriate, tease, or terrify it, or permit it to be so treated." Any person committing such an offence may be proceeded against under the Summary Jurisdiction Acts, and on conviction is liable to be imprisoned for three months or fined £5.

A REUTER telegram from St. Petersburg states that the Imperial Academy of Science has just received news from the Russian expedition at Spitsbergen stating that in the month of September last the members of the expedition in question had erected, at Horn Sound, observatories for conducting meteorological, magnetic, astronomical and astrophysical researches. On October 20 the sun disappeared for four months, and at the end of October absolute and continuous night set in. The members of the expedition applied themselves constantly to scientific observations after November 17. On February 22 the sun was seen again for the first time. On June 5 and 8 the first boats arrived, ending the complete isolation of the expedition, which had lasted for nine months.

THE annual meeting of the French Association for the Advancement of Science was recently held at Paris. General Sebert, the president, delivered an address on the progress of mechanical industries and the means of developing them. In the course of his remarks he alluded to the value of technical education and research as factors in national advances. "It is noteworthy," he said, "that progress in mechanical industries has always coincided with the development of technical education in the countries in which the industries are carried on. The most rapid progress takes place in the countries where institutions for experiment and research are most numerous. Wherever research laboratories have been established to permit the study of the best conditions of invention, there the most marked advances first take place." The Association's grants for scientific purposes, made at the recent meeting, amounted to 21,241 francs, or about 850*l.*

MR. A. R. HUNT, writing from Torquay with reference to our note (p. 322) on the rumbling sounds heard at Bognor and Torquay on July 18, says: "I happened to go into my garden a few minutes after ten on the date named, and was at once conscious of a very unusual pulsating rumble. My first idea was earthquake, but the sound came steadily from one point, roughly south-east; and at last died away into distinct taps." The observation is interesting in showing how far the individual reports can be heard (see p. 378).

MR. J. STIRLING, Government geologist of Victoria, New South Wales, is at present in London as the mining representative of the Victorian Government, and during his stay here proposes to address some of the scientific, professional and mining organisations of the United Kingdom on matters of origina research in Australasia. He will give an address at the Convention of Mining Institutes of Cornwall during August, and subsequently at Manchester, Bristol and other centres.

SOME interesting information as to the actual experience of nations who have adopted the metric system is given in a number of reports from Her Majesty's consular and other officers in Europe, which have just been brought together and published by the Foreign Office. H.M. representatives in twenty-two States were asked to give information upon the following points. (1) The ease or difficulty with which the change of systems was made, the manner of introduction of the metric system, and the time occupied in making the change; (2) How far the metric system is satisfactory in its practical operation, and whether there is any desire to return to former systems; (3) As to the effect the adoption of the metric system has had upon the commerce of the nations adopting it. The answers received to these questions go to show that the best way to introduce the metric system is to make it compulsory after a specified period. The change from the old to the new system is slow in country districts, but as new generations come on familiar with the metric measures the old measures gradually drop out of use. In Turkey, the difficulties of enforcing the system upon an ignorant and illiterate people have proved insurmountable; but in the majority of States from which information has been received, the system is becoming more extensively used every day. Once the system has been adopted there is no desire to return to the old measures, and the effect upon commerce is always beneficial. In fact, the reports greatly strengthen the position of those who urge that the metric system should be adopted in England, if only for the sake of British trade.

IT was mentioned in these columns some time ago that the wire fencing of great sheep farms in some parts of Australia was used as telephone wires. A recent report from H.M. Consul at Philadephia states that this system of communication is being employed by farmers between the towns of Anderson, Pendleton and Ingalls, in Indiana. The top wire of a barb-wire fence is used as the conductor, the continuity of the line being assured by special devices at highways and railway crossings. The line is fourteen miles in length with five stations, two at Anderson, two in Pendleton, and one at Ingalls. Local farmers state that they have used the "fence-line" to converse with friends eight miles distant, and this at a time when the fence posts were still saturated with the morning dew, a condition under which the line is supposed to work with least satisfaction. It is stated that the line has been such a practical success that the farmers of the neighbourhood are organising companies for the purpose of placing themselves in telephonic communication throughout the whole district.

AN excellent article dealing with the photographic side of the suggestions as to analytical portraiture made by Mr. F. Galton in NATURE of August 2 appears in *Photography* of August 9. Illustrations are given of results obtained by combining two portraits of a single person in the same pose, but having different expressions during the two exposures. In one picture the sitter has a normal expression; in the other he is smiling. A transparency was made from the normal negative; and when this positive and its negative were superimposed they neutralised one another. But by placing the positive of the normal expression of face upon the negative of the smiling expression, the two do not, of course, exactly obliterate one another. Certain parts of the features are common to both, and these disappear when the different positive and negative are superimposed, leaving only portions which represent the smile of the sitter's features. In a similar way, by superimposing the positive of a glum portrait upon the negative of a normal expression, it is possible to obtain differences representing an individual's glumness. Readers of "Alice in Wonderland" will remember that the Cheshire cat gradually disappeared and left only its grin behind. This facetious idea has now been realised, for as our enterprising contemporary points out, Mr. Galton's analytical portraiture shows how the factors of a grin or a scowl can actually be discriminated, so that a grin can be obtained without the face upon which it appeared.

A REUTER telegram from Liverpool, dated August 12, makes the following announcement:—The second malarial expedition of the Liverpool School of Tropical Medicine has just wired home from Bonny, in Nigeria, news of a most important discovery—viz. that the parasite which causes elephantiasis has, like that which causes malaria, been found in the proboscis of the mosquito. Oddly enough, the same discovery has just been simultaneously made by Dr. Low in England in mosquitoes brought from Australia, and by Captain James in India. Elephantiasis is a disease which causes hideous deformity in thousands, or rather millions, of natives in tropical countries, and sometimes in European residents. It is due to a small worm which lives in the lymphatic vessels and occludes them. The fact that this worm can live also in the mosquito has long been known, but the discovery of it in the insect's proboscis shows that it enters the human body by the bites of these pests. Europeans in the tropics are indebted to mosquitoes, not only for much discomfort, but for two dread maladies—malaria and elephantiasis; and it is high time that the authorities should begin seriously to consider Major Ross's advice to destroy these insects or their breeding-places wherever practicable.

THE medical papers contain detailed reports of the Thirteenth International Congress of Medicine, which was held in Paris at the beginning of this month under the presidency of Prof. O. M. Lannelongue. Among the representatives of Great Britain were Sir William MacCormac, Sir T. Lauder Brunton, Sir J. Burdon Sanderson, Sir Dyce Duckworth, Sir Felix Semon, and Prof. Simpson. A banquet in honour of Lord Lister was arranged by Prof. Charles Richet and the "Scientia" social society. Speeches expressing admiration of Lord Lister's work, and describing the influence it has had upon various branches of medical and surgical science, were made by Prof. Richet, Dr. Bouchard, Prof. Guyon, Dr. Lucas Championnière, and Dr. Pinard. In his reply, Lord Lister said he regarded the banquet as being in honour of the noble science of surgery and the Royal Society of London, of which he was the president. It showed that the scientific world knew nothing of the misunderstandings between peoples of different nationalities, and that men of science had mutual respect for one another at all times. Lord Lister added: "I have often said, and it gives me pleasure to repeat it this evening, that I owe much to Pasteur. It is true that I was passionately fond of physiology and surgery. The nature of inflammation was the subject of my first investigations. As a surgeon, I deplored the disastrous results which often followed the most skilful operations, and I saw, what many others had doubtless remarked before me, that the most important troubles of a wound were due to changes in the tissues of the body after the operation, and had an external origin. But all my efforts to avoid these complications were unavailing until Pasteur threw a new and strong light upon the subject, and indicated a possible course of action which I have done my best to follow. That is all. If my efforts have been followed by such beneficial results as have been generously described by speakers this evening, the success must, in a great measure, be ascribed to the fortunate chance of my time."

THE report of the Zoological Gardens of Ghizeh, near Cairo, for the year 1899, gives a good account of the progress of this Institution, which, under the rule of its present director, Captain

Stanley Flower, has become a popular place of resort for the European visitors to Egypt, as well as for the Cairenes. The receipts in 1899 were 3033*l.*, of which 968*l.* were for gate-entrances, and the expenditure was 3019*l.* The list of donors includes many well-known names, amongst which we see those of Sir William Garstin, Prince Omar Tousson, Sir F. Wingate and Lord Kitchener. The Government of India presented an elephant. Various new buildings were erected, and others were reconstructed in 1899. The number of animals in the collection on October 1 of that year was 473, against 270 at the corresponding date in 1898. A list of wild birds that inhabit the Ghizeh Gardens, and in many cases breed there, enumerates nineteen species, amongst which is the European song-thrush (*Turdus musicus*). Two proboscis monkeys (*Nasalis larvatus*), presented by the Government of the Netherlands East Indies, unfortunately did not live long. We are informed that since the report was issued Captain Flower has succeeded in bringing to the Ghizeh Gardens from the Sudan a fine young giraffe, presented by the Sirdar.

WRITING from Mashonaland in May, Mr. G. A. K. Marshall raises, in the August number of the *Entomologist*, what appears to be a pertinent question with regard to mosquitoes and malaria. If it be admitted, he observes, that malaria can only be carried by mosquitoes of the genus Anopheles, and that these insects can only acquire the microbes from malarially-infected man, "then we are logically bound to accept the conclusion that if a man, or party of men, free from malarial poison, should penetrate from a healthy area into an unhealthy but uninhabited region, it would be impossible for them to contract fever, however much they might be bitten by mosquitoes. Further, it follows that all uninhabited regions, even of comparatively small size (seeing that the range of individual species of Anopheles is apparently very limited in extent) must be entirely devoid of malaria, even though they may be full of swamps and teem with mosquitoes." Such conclusions are, however, contrary to experience, and if the writer's premises be correct, his difficulty requires an explanation at the hands of specialists.

THE Walcott collection of Hymenoptera, now in the Cambridge University Museum, has yielded to the researches of Mr. R. C. L. Perkins (*Entomologists' Monthly Magazine* for August) a species (*Odynerus tomentosus*) new to the British fauna. Considering that the greater part of the collection was made in the first half of the century, it is not a little remarkable that the species should have escaped notice so long.

THE large scale on which they do things in America has become a proverb. An instance is afforded by Mr. J. B. Smith's description of one hundred new species of moths of the family Noctuidæ in vol. xxii. of the *Proceedings* of the U.S. Museum.

TO vol. xxix. No. 13 of the *Proceedings* of the Boston Society of Natural History Dr. H. S. Pratt contributes an important paper on the embryological history of the so-called imaginal discs of the sheep-tick (*Melophagus ovinus*). For the benefit of our non-entomological readers it may be mentioned that these imaginal discs, or folds, are structures in the larva and pupa which do not participate in the general breakdown of tissue at the periodical changes, but undergo continuous development into the corresponding parts of the perfect insect. Hitherto, the author says, these structures have been studied only in the larval and pupal stages; and he for the first time describes their origin and early stages of growth.

FOUR out of the nine papers in Part i. of the *Proceedings* of the Philadelphia Academy for 1900 are devoted to the land and fresh-water molluscs of America. In the first of these Mr. C. T. Simpson describes a number of new or unfigured river mussels (Unionidæ); the second, by Mr. W. H. Dall, treats of the land-shells of some of the Pacific Islands, more especially those of the Galapagos and Cocos groups; in the third, Mr. H. A. Pilsbry discusses the anatomy of the helicoid genus Ashmunella, and in the fourth the molluscs of the Great Smoky Mountains. This last communication is perhaps the one of most general interest, since the author is of opinion that the cleft in the Appalachian chain formed by the valley of eastern Tennessee indicates the boundary between two zoögeographic provinces. The lists of terrestrial molluscs given by him as respectively characteristic of the eastern and western divisions of this portion of the chain seem to bear out his contention as to the existence of two distinct faunas.

THE sixth of the series of physico-mathematical handbooks published by Messrs. Carré and Naud, of Paris, under the title of "Scientia," is a small treatise by M. Fred. Wallerent on crystalline groups and their optical properties. As an introduction to modern crystallography the little volume should be of much use to those interested in other branches of science who are desirous of acquiring a general knowledge of the history and fundamental principles of the subject, and who do not possess the spare time for mastering a larger treatise.

IN a short note contributed to the *Atti del R. Istituto d'Incoraggiamento* (Naples), Prof. E. Semmola discusses the state of our knowledge of the variations of the electrical potential of the air with the altitude. In reference to Le Cadet's result that the potential decreases with the altitude, Prof. Semmola points out that the late Prof. L. Palmieri, in conjunction with himself, had established a similar property previously. Le Cadet found that the potential decreased from 150 to 44 volts in the first kilometre of altitude, and deduced that the potential decreased much less rapidly at greater altitudes. But Semmola thinks that the high potential found at the surface of the earth was at any rate in part due to the obscurity of the superincumbent air.

A SHORT note on the reflection of light in the neighbourhood of the critical angle is given by Mr. J. G. Coffin in the *Technology Quarterly*, the object being to examine more fully than is done in most text-books the consequences of applying Fresnel's formulæ to refraction from a denser to a rarer medium. Tables are calculated by the author and Prof. Pickering, showing the percentages of light reflected at different incidences in passing from a rare to a dense medium and *vice versâ*, and the results are exhibited graphically by curves. The paper thus contains an amplification of the superficial information contained in the majority of treatises on optics.

IN the *Journal of Proceedings* of the Institution of Electrical Engineers, xxix. 142, 1900, Mr. Alexander Russell discusses the question how condenser and choking-coil currents vary with the shape of the wave of the applied electromotive force. Various forms of wave being considered, the author finds that the sine curve wave produces the least effective current when applied to a condenser, and the largest magnetising current when applied to a choking-coil. Similar results are established for the symmetric wave in the case of a family of waves of equal height. The subject is sufficiently interesting to make us wish for a fuller mathematical investigation, Mr. Russell's note being a mere statement of results.

SOME tests of fire retardent materials are described by Mr. Charles L. Norton in the *Technology Quarterly*, xiii. 2, for June 1900. The tests were made on October 5, 1899, and February 3, 1900, by setting up small buildings previously constructed in the Massachusetts Institute of Technology and building a fire of wood and oil inside. Observations of the progress of the fire and of the subsequent state of the wooden backing led to a number of interesting conclusions as to the value of the protection afforded by various retardent materials. Among these we note the comparative value of a wooden and metallic lath; the necessity of applying fire retardent material in at least two thicknesses so as to break joints; the immense superiority of three-ply over two-ply doors; the advantage of the Atkinson composite door as being more gas-tight than a wooden door; the fire-resisting qualities of three-inch plank as compared with one-inch boards, or lath and plaster; the excellency of Mississippi wire glass; and the satisfactory performance of "King's Windsor" cement and "Adamant" plaster.

AN important development of the electron theory has been carried out by Robert Lang in his article on atomic magnetism contributed to the *Annalen der Physik* (No. 7). It may now be said that the phenomena of magnetism have at last been successfully reduced to those of electricity. We know from the work of Thomson and of Drude that an electric current in a wire consists of a stream of very small particles called electrons. These electrons are formed by the splitting up of the metallic atoms into a larger positive and a smaller negative portion. The positive electrons, under the influence of an electromotive force, travel in one direction along the wire, with a velocity of about 1 cm. per second. The negative electrons travel in the opposite direction with the same charge, but with a smaller velocity. The masses are in the ratio of about 9 : 1. Now according to Lang, the negative electrons revolve round the heavier positive electrons in a magnetised metal, like a planet round the sun, and the electric convection currents thus produced are nothing more or less but Ampère's "elementary molecular currents." Lang calculates the speed of the electrons and the diameter of their orbit. The speed is that of light, and the figures obtained lead to conclusions in close agreement with known facts.

AN interesting article, entitled "Cartographie de la Caverne Mammoth," is contributed by Dr. H. C Hovey to the *Bulletin de la Société de Spéléologie*, tome v. 1899. The author gives a short history of the attempts to map the celebrated Mammoth Cave, and points out that, owing to objections on the part of the proprietors, the scientific investigation of these caverns is still incomplete. The paper is accompanied by reproductions of the map by Hovey and Call, and that by C. R. Blackall for purposes of comparison.

A VALUABLE addition to our knowledge of the cretaceous geology of Saxony is furnished by Dr. W. Petrascheck in a paper published in the *Abhandl. der Naturwiss. Gesellsch. Isis* (Dresden, 1900). The author seeks to trace the change of facies developed at various horizons in the cretaceous rocks of this area when followed laterally. He explains, as far as possible, the modifications in the character of the fossil fauna which accompany the changes in petrographical facies. The region discussed comprises the neighbourhood of Dresden and the well known "Saxon Switzerland."

THE August number of the *Journal* of the Chemical Society contains the Friedel Memorial Lecture, delivered before the Society by Prof. J. M. Crafts.

THE second English edition of Prof. Ostwald's "Scientific Foundations of Analytical Chemistry," translated from the second German edition by Dr. George M'Gowan, has been published by Messrs. Macmillan and Co. Since the original work was published in 1894, the principles expounded in it have been steadily gaining acceptance, but, so far as we are aware, no English text-book of chemical analysis has appeared in which he analytical methods and reactions of the laboratory are consistently explained in terms of the theory of ions instead of being represented by the ideal equation-formulæ. As Prof. Ostwald states, the general standpoint of analytical chemistry has undergone but little change; nevertheless, the newer ideas are gradually being applied to laboratory work by lecturers and demonstrators who are in touch with modern chemical theory. The new edition just published will be the means of extending the knowledge of the fundamental principles underlying chemical processes, and will be a source of inspiration to teachers who wish to make analytical chemistry a science as well as an art.

A SIMPLE method of preparing free hydroxylamine is given in a recent number of the *Annalen* (311, 117) by Dr. R Uhlenhuth. When the phosphate of the base is heated gently under reduced pressure, the base distils over in a state of such purity that the distillate solidifies on placing the receiver into melting ice.

THOUGH the need for a universal standard table of atomic weights is recognised by all chemists, the question whether it shall be constructed upon a basis of $O = 16$ or $H = 1$ has yet to be decided. The *Chemical News* publishes a letter from Profs. Bredt, Erdmann, Fischer, Volhard, Winkler and Wislicenus, members of the International Committee on Atomic Weights, upon this point. It is remarked that if cogent reasons necessitate an alteration of the standard of atomic weights, it would be better to start from an element of which the weight can be conveniently ascertained, such an element, for example, as silver or iodine, which also serves as a practical starting-point in consideration of the sharpness of its reactions in numerous analytical operations. But in the opinion of the writers such cogent reasons for an alteration do not present themselves, for the ratio of hydrogen to oxygen has been established with an exactness which fully suffices for all practical purposes. It is felt that the time for an unchangeable table of atomic weights has not yet come; for each succeeding year brings corrections in the atomic weights of the rarer elements, and at the same time speculations as to their simple or compound nature. Opinions are therefore invited upon the following questions:—(1) Shall the unity of hydrogen be retained as the standard for reckoning atomic weights? (2) Shall the atomic weights be given approximately with two decimal places in which the uncertain figures can be recognised by the type? (3) Shall the International Atomic Weight Commission have the current table of atomic weights edited on this basis? Communications should be sent to Herr Prof. J. Volhard, Mühlpforte 1, Halle-a-S.

THE additions to the Zoological Society's Gardens during the past week include a Lioness (*Felis leo*) from South Africa, presented by the Right Hon. Cecil J. Rhodes; a Black-backed Jackal (*Canis mesomelas*), a Leopard Tortoise (*Testudo pardalis*), a Puff Adder (*Bitis arietans*) from South Africa, presented by Mr. J. E. Matcham; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mr. W. A. Gillett; a Blue and Yellow Macaw (*Ara ararauna*), a Red and Yellow Macaw (*Ara chloroptera*) from South America, presented by Captain G. H. Arnot; a Chinese Quail (*Coturnix chinensis*) from China, two Asiatic Quails (*Perdicula asiatica*) from India, two Sparrow Hawks (*Accipiter nisus*), British, presented by Mr. D. Seth-Smith; a Common Quail (*Coturnix communis*), British, presented by Miss F. E. Burt; a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, a Polar Bear (*Ursus maritimus*, ♀) from the Polar Regions, two Black-headed Caiques (*Caica melanocephala*) from Demerara, a Smooth-headed Capuchin (*Cebus monachus*) from South-east Brazil, a Pleurodele Newt (*Molge walti*), a Leopardine Snake (*Coluber leopardinus*), a Vivacious Snake (*Tarbophis fallax*), six European Pond Tortoises (*Emys orbicularis*), South European; two Egyptian Mastigures (*Uromastix spinipes*), an Algerian Tortoise (*Testudo ibera*) from North Africa, four Alligator Terrapins

(*Chelydra serpentina*) from North America, a Leopard Tortoise (*Testudo pardalis*) from South America, two Argentine Tortoises (*Testudo argentina*) from the Argentine Republic, deposited; a Gold Pheasant (*Thaumalea picta*, ♂) from China, two Little Bitterns (*Ardetta minuta*), European, purchased; a Burrhel Wild Sheep (*Ovis burrhel*), born in the Gardens.

## OUR ASTRONOMICAL COLUMN

COMET BORRELLY-BROOKS (1900 *b*).—The following elements and ephemeris are furnished by Herr J. Möller in the *Astronomische Nachrichten* (Bd. 153, No. 3654).

*Elements.*

T = 1900 Aug. 3·298 Berlin Mean Time.

$$\left.\begin{array}{rrr}\omega = & 12^\circ & 30'\cdot2\\ \Omega = & 328 & 1\cdot8\\ i = & 62 & 35\cdot6\end{array}\right\}1900\cdot0$$

$\log q = 0\cdot00636$

*Ephemeris for* 12*h. Berlin Mean Time.*

THE ASTROGRAPHIC CHART CONFERENCE.—The fourth meeting of the International Committee for directing the photographic delineation of the sky has recently been held in Paris, commencing July 19. The first matter taken in hand was the appointment of a sub-committee of nine astronomers to draw up a scheme for the systematic observation of Eros during the coming opposition, for determinations of solar parallax. The reports from the co-operating observatories show that in fifteen of them the work is being vigorously pushed forward; unfortunately, in the remaining three, Rio de Janeiro, La Plata and Santiago (Chili), the work has entirely fallen through.

Dr. Thome, of the Cordoba Observatory, has been enabled, by the generosity of the Argentine Government, to volunteer for the work assigned to La Plata (−24° to −31°), and M. Enrique Legrand stated that he had induced his Government to found an observatory near Monte Video (Uruguay) to carry out the zone (−17° to −23°) allotted to Santiago. It was also suggested that the new observatory at Perth, West Australia, might possibly carry out the work on the remaining zone (−32° to −40°).

Another important item of the discussion was the advisability of publishing the rectangular co-ordinates of the stars as measured, with, of course, the constants of each plate, or delaying the work until these could be transferred to equatorial co-ordinates. It was considered that in the near future the absolute positions of the comparison stars would be much more accurately known than at present. The only drawback to this scheme is that Dr. Scheiner, of Potsdam, has already started the publication of the catalogue giving R.A. and Decl. of the stars.

In connection with the assignation of photographic magnitudes, it appeared to be generally believed that the estimation of diameters by means of a scale is a surer plan than measurement with a micrometer for this particular branch of work, but no definite ruling was given on this point.

The original plan agreed to in 1896 for taking the chart plates with three exposures of 30m. each has not been followed at all the observatories, and it was resolved at this meeting that in future the method of taking the chart plates shall be decided by the individual directors. In the reproduction of these chart plates, it is unlikely that uniformity will be secured; the French observatories have made enlarged copies by heliogravure, but as each observatory would have to expend some 10,000*l.* to do this, the actual method of reproduction is left unsettled.

DETERMINATION OF SOLAR PARALLAX.—A circular has been issued by the special committee appointed by the International Astrophotographic Conference held recently at Paris containing the resolutions passed for systematising the work to be done at all the world's observatories during the coming autumn and winter, when it is hoped, by means of observations of the minor planet Eros, to determine the parallax and distance of the sun with a degree of accuracy previously unattainable. The following is a summary of the suggestions adopted:—

(1) That the determination of parallax of Eros be made by micrometric, heliometric and photometric measurements. (*a*) By observations of the planet east and west of the meridian at the same observatory. (*b*) By the co-operation of the observatories of Europe and North America. (*c*) By the co-operation of the observatories of the northern and southern hemispheres.

(2) During the period of parallax observations the diurnal movement of Eros should be determined as accurately as possible by heliometer, micrometer and photography.

(3) (*a*) Observers determining the parallax in right ascension should make measures each night and morning, profiting by all favourable circumstances to operate with as large hour angles as possible. (*b*) Observers finding parallax by difference of declination in northern and southern hemispheres, should arrange that the mean instants of observation do not vary much from the meridian passage of the planet at the southern station.

(4) It is necessary that special series of photographs be taken of the region traversed by Eros, in order to furnish accurate determinations of the positions of comparison stars.

As the varying atmospheric conditions will play an exceedingly important part in the observations, particularly those away from the meridian, MM. André and Prosper Henry have been asked to prepare suggestions for eliminating these difficulties.

At the time of writing, the following observatories have signified their intention of helping with the scheme:—Algiers, Athens, Bamberg, Bordeaux, Cambridge (England), Cambridge (U.S.), Cape of Good Hope, Catania, Cordoba, Chicago (Yerkes), Edinburgh, Greenwich, Heidelburg, Leyden, Leipzig, Lyons, Marseilles, Minneapolis (U.S.), Mount Hamilton (Lick), Nice, Potsdam, Rome, San Fernando, Strassburg, Tacuboya, Toulouse, Upsala, Vienna (Ottahring), Vienna (Währing), Washington.

## THE DISTANCE TO WHICH THE FIRING OF HEAVY GUNS IS HEARD.

IN a discussion which took place in NATURE some time ago on the so-called "Barisâl Guns" and other mysterious sounds, Prof. Hughes suggested that it would be desirable to ascertain how far the firing of guns can be heard (vol. liii. p. 31). In connection with another subject, that of spurious earthquakes (see NATURE, vol. lx. pp. 139–141), I have for some time been collecting notes on this point, and I propose here to describe some of the facts obtained, chiefly with regard to the great naval review at Spithead on June 26, 1897, and the operations of the French fleet at Cherbourg on July 18, 1900.

I will mention first a few cases referring to more or less isolated observations of the reports of distant guns. The firing during the battle of Camperdown on October 11, 1797, is said to have been heard in Hull, the distance between the two places being more than 200 miles. A gentleman, formerly resident at Kertch in the Crimea, informs me that he has heard the sound of the guns fired at Sebastopol, distant 158 miles. During the American Civil War, the roar of the guns at the battles of Malvern Hill and Manassas (or Bull Run) was perceptible at

Lexington in Virginia, the distances being about 123 and 125 miles respectively (NATURE, vol. liii. p. 296). When the *Alabama* was sunk nine miles off Cherbourg on the morning of Sunday, June 19, 1864, the sound of the guns was heard in Jersey, at Clyst St. George, near Exeter (108 miles from Cherbourg), and at Brent Tor, near Bridgwater (about 125 miles). The great naval review at Spithead on July 17, 1867, was held during rough, boisterous weather; but the noise of the guns is said to have been heard at Exeter (105 miles), Morebath, near Tiverton (105 miles), Great Malvern (107 miles), and Castle Frome in Herefordshire (110 miles). In all the above cases the sound was, of course, the aggregate of that of many guns of different sizes fired simultaneously. But, in naval reviews, the charge is very much less than in actual warfare; a 6-inch gun, for instance, would fire a blank charge of 7 lbs., whereas the service charge for the same gun would be 48 lbs. fired with shot.

With regard to the distance to which the report of a single gun can be heard, I have very little information. A 110-ton gun fired at Woolwich made a window shake at Chignall St. James (24 miles), and was heard at Witham (32 miles) as a rumbling sound which seemed to deafen the observer slightly (NATURE, vol. xli. p. 369). Time-guns at Bombay have been often heard at the northern Mahim, distant more than 50 miles (vol. lvi. p. 223). The reports of the heavy guns at the battle of Malvern Hill, mentioned above, could be easily distinguished at Lexington from those of the smaller weapons; and a similar observation is recorded below. The subject is evidently one on which useful contributions to our knowledge might be made by residents near the south coast of England.

### *Naval Review at Spithead on June* 26, 1897.

Shortly before the great naval review held in honour of the Queen's Diamond Jubilee, I wrote to the principal London newspapers and to several published in the south of England, and I have to thank the editors of these papers, and the ladies and gentlemen who replied to my inquiries, for the help they have kindly given me. The points to which I directed attention were the times at which the reports were heard, whether the air-vibrations were strong enough to make windows rattle, the direction from which the sound appeared to come, and the direction of the wind.

The fleet collected on this occasion consisted of 165 vessels of war of all classes arranged in five lines about six miles in length. The position of the flag-ship (H.M.S. *Renown*) was about two miles N. 20° E. of Ryde; and the distances given below are all measured from this point. As the Royal yacht entered the lines immediately after 2 p.m., the first shot was fired from the *Renown*, and was taken up by other ships in turn, each firing a Royal salute of twenty-one guns. "The heaviest gun employed," I am informed by the Secretary of the Admiralty, "was probably a 6-inch breech-loading gun, firing a blank charge of 7 lbs."; but others of different sizes were also used. It produced at first a dull crackling noise, according to a correspondent on H.M.S. *Sanspareil*, but, as ship after ship took up the salute, the firing grew more animated and the roll of the guns louder; until, after about five minutes, the report of the last gun died away.

The atmospheric conditions were fairly favourable for the propagation of the sound. Light, but variable breezes, generally between north-east and south-east, prevailed over most of the south of England. The thunderstorms which occurred on that day followed the salute in most places, but nearly all my correspondents (several being retired military officers) agreed that the sound of the guns could be readily distinguished from that of thunder.

In many of the records which I have received, the time is given so roughly that it is difficult to feel confident that they refer to the salute in question, and in several it is omitted altogether. Under the former heading come records from Honiton (90 miles from Spithead) and Shebbear, near Torrington (135 miles); and under the latter from near Rickmansworth (67 miles) and Great Malvern (107 miles). Excluding all such cases, the number of records is reduced to twenty, from nineteen places.

At very few of these places, and at none more distant than about 28 miles, were the vibrations strong enough to shake windows. Distinct reports were heard at the beginning and end of the salute as far as Farnham (34 miles), otherwise the sound was a dull, continuous roar, with occasional booms from the heavier guns. The sound was heard to the east as far as Framfield (57½ miles), to the north-east at Wimbledon (62 miles), to the north at Bloxham Green, near Banbury (88 miles), and to the west at Wellington in Somerset (93 miles). These are more or less isolated places, but there is a fairly continuous series of observations in a north-westerly direction, extending to Melksham (61 miles), Monkton Farleigh, near Bradford-on-Avon (67 miles), Bath (two observations, 69 miles), and Weston, near Bath (71 miles).

In the evening the fleet was illuminated, and a final Royal salute, similar to that at 2 p.m., was fired on the return of the Prince of Wales shortly after 11 p.m. I have only two accounts which may refer to this salute, one from Cosham in Hampshire at 11.30 p.m., the other from Ashburton in Devonshire (116 miles) at 11.59 p.m. The recorded times differ too widely to give much value to these observations.

### *Naval Review at Cherbourg on July* 18, 1900.

About 10 p.m. a sham fight took place between two portions of the French fleet at Cherbourg in honour of the visit of the President, M. Loubet, to that town. The number of vessels engaged was forty-three, including thirteen of the largest and most modern battle-ships in the world. During the next few days accounts appeared in various English newspapers of a series of supposed earthquake-shocks felt shortly after 10 p.m. at different places along the southern coast, from Torquay to Bognor. The long duration of the disturbances and their apparent transmission through the air being opposed to a seismic origin, I wrote letters to a number of London and south-country papers, and the account which follows is chiefly based on the replies which I received to these letters.

As some doubt has been expressed with regard to the connection between the two phenomena, it may be well to mention the evidence in its favour. (1) With two exceptions, not one of the places (forty in number) from which records have come is more than a mile or two from the coast. There are several from the south of the Isle of Wight, but none from that part of Hampshire shielded from Cherbourg by the higher ground of the island. (2) Though a few persons in the open air assert that a tremor was felt, the great majority state that the sound travelled through the air and not through the ground; windows rattled loudly without there being any movement of the floor, and at Lancing (100 miles from Cherbourg) and Seaton in Devon (97 miles) observers placing their hands on the wall felt it distinctly vibrating; the noise caused a drumming in the ears at several places more than a hundred miles from Cherbourg. (3) The sounds were recognised as those of heavy guns by many persons, and with less hesitation the smaller the distance from Cherbourg. (4) The night was very still, hardly a breath of wind could be felt, and the sea perfectly calm; and the sound was heard to the east and west along the English coast at almost equal distances from Cherbourg. (5) Lastly, heavy guns are rarely, if ever, fired from English ships or forts at so late an hour; whereas more than 24,000 charges are said to have been fired in Cherbourg harbour during almost the same interval in which the sounds were heard in England.

Though the times of occurrence are roughly given, they agree for the most part in placing the commencement of the disturbances just after 10 p.m., and the end shortly before 10.30. Clearer evidence as to the identity of the sounds throughout the whole area affected is provided by the similarity in their relative duration and intensity. The first began about 10.2 or 10.3, and lasted nearly four minutes. Then came a pause of five minutes, when there was another burst of about the same intensity and nearly the same duration. About ten minutes later the third followed, slighter in intensity and of shorter duration, perceived almost as far as the others (at Torquay and Brighton, 101 and 104 miles respectively), though not by all observers.

I have no information as to the size of the guns used on this occasion, but they were probably much heavier than those employed for the salutes at Spithead in 1897. To the west, the sound was heard at Budleigh Salterton, Sidmouth and Torquay (101 miles from Cherbourg), Paignton (102 miles), and Dawlish and Exmouth (104 miles); to the east at Lancing (100 miles), Brighton (104 miles), and near Henfield (107 miles, and seven miles from the sea). At all of these places, and at many between, the air-vibrations were strong enough to make windows shake and rattle, and there are accounts of this or a similar effect being observed at a greater distance than the sound—at Plymouth (123 miles), and Menheniot, near Liskeard (136 miles, and five miles from the sea). At the latter place the sudden rattling of a large window was distinctly heard at about 10 p.m., but it was unaccompanied by any sound. Judging from the intensity of the disturbances at Torquay and Brighton, I see no reason to doubt the connection of the latter observation with the firing at Cherbourg.

It is interesting to notice how the character of the sound changed with the increasing distance from Cherbourg. At St. Catherine's Point (65 miles) and Bonchurch (68 miles), both in the Isle of Wight, the sound was described as exactly like that of heavy guns. At Bournemouth and Muddiford in Hampshire (74 miles) there was a continual rumbling noise, with occasional heavier booms. At greater distances, as far as Lancing, Torquay and Paignton, the prominent reports ceased to be audible, and there was merely a deep monotonous throbbing noise, the pulsations recurring with great rapidity and regularity, resembling a very quick beating of a big drum far away, or the beats of the paddles of a distant and unseen steamer. At very great distances the vibrations (or some of them) do not seem to have attained the requisite strength to be audible to certain observers, one at Lancing (100 miles) referring to a most curious throbbing sensation in the air, and a dull sound like that of a distant train; while another at Brighton (104 miles) remarks that he heard or felt the sound. The rattling of the window and the inaudibility of the vibrations at Menheniot may perhaps be accounted for in this way.

CHARLES DAVISON.

---

## *SUBJECTS FOR CONSIDERATION BY ELECTRICAL ENGINEERS.*

THE current number (July) of the *Journal* of the Institution of Electrical Engineers contains a list of subjects suggested by the Council as suitable for papers to be read at the meetings or published in the *Journal*. The list is here reprinted, and it should be the means of directing attention to many important problems awaiting solution, as well as eliciting information upon the present position of various branches of electrical engineering.

1. Best methods of generating steam and steam power for variable loads.
2. Comparison of double- and triple-expansion engines for varying load conditions.
3. Automatic handling of fuel in power stations.
4. The present position and applicability of gas or oil engines for electrical power stations.
5. Description of plants for the utilisation of river- or tidal-power in the generation of electrical energy.
6. The present position and prospects of the application of liquid and of powdered fuel in electrical power stations.
7. The utilisation of blast-furnace gases or other waste products of manufactures in the generation of electricity.
8. The application of dust-destructors to the generation of electricity.
9. Electric light and power station chimney shafts; specialities of their construction and equipment.
10. Experiences with vibrations from electric light and power stations.
11. Bearings of shaft and shafting running at high speed.
12. Improvements in dynamos.
13. Comparison of speed and cost of dynamo.
14. Comparison of single and multiple central stations.
15. The wholesale supply of electricity to towns and factories from centres where very large generating units are employed.
16. The distribution of electrical energy from a distant generating station through districts served from a different source of supply, or under a separate local authority.
17. Electrical distribution by constant current, direct or alternating.
18. Examination of relative advantages and disadvantages of direct-current and alternate-current transmission.
19. Examination of relative advantages and disadvantages of two-phase and three-phase transmission.
20. Methods of controlling speed of alternating current motors.
21. Practical methods of measurement in connection with polyphase distribution.
22. Methods for the conversion of direct current into alternate current.
23. Methods of providing for electrical supply during hours of small demand.
24. Utilisation of lighting plant for other work during the hours of small demand.
25. The electrical equipment of large blocks of offices in a city.
26. Economy of design in the manufacture of small electric fittings.
27. Portable electric lamps of the "safety" type, or otherwise.
28. Enclosed arc lamps.
29. Improvements in incandescence electric lamps.
30. Incandescence electric lamps with filaments other than pure carbon.
31. Application of electrical transmission in factories:—
    (*a*) Detailed description, giving sizes of motors and power provided.
    (*b*) Comparison of separate or combined direct- and alternate-current methods.
    (*c*) Combination of lighting and power for such purposes
32. Electricity meters.
33. Description of electrical methods, or comparison of these with other methods, of propelling vehicles.
34. The supply of electrical energy for tramway purposes.
35. The use of electrical methods of traction on railways served by steam-driven locomotives.
36. The economy and design of electrical elevators.
37. The design and economy of electrically driven pumps.
38. The utilisation of electrical energy in mining.
39. The applications of electrical energy in warfare.
40. The use of electricity in the textile and other industries.
41. The application of electricity in musical instruments.
42. Electro-therapeutics.
43. The establishment of public time-services by electricity.
44. Recent advances in telegraphy.
45. Applications of alternating currents in telegraphy.
46. The transmitting capacity and load factor of telegraph circuits.
47. Hertzian telegraphy.
48. Methods, in aërial telegraphy, of restricting signals to selected stations.
49. Recent improvements in telephony.
50. Descriptions of systems tending to simplify the interchange of telephonic communications.
51. The talking capacity and load factor of telephone circuits.
52. The application of electricity to the generation of heat for domestic purposes (cooking, ventilation, heating, &c.).
53. The construction and use of electric furnaces.
54. The application of electricity to the welding or annealing of metals.
55. The application of electrical heating methods in chemical or metallurgical operations.
56. The applications of electricity in metallurgical processes.
57. The applications of electrolysis in the smelting or refining of metals, or in the chemical industries.
58. The electrical equipment of chemical factories.
59. Improvements in primary batteries.
60. Examination of the present position of secondary batteries in electrical engineering.
61. The direct generation of electrical energy from fuel.
62. The economic employment of thermo-generators.
63. Improvements in the apparatus for producing, and in the applications of, kathode and Röntgen rays.
64. The relative suitability and efficiency of the different materials available for any of the requirements of electrical engineering.
65. The electric strength of di-electrics.
66. Recent advance in the manufacture or use of insulating materials.
67. New insulating materials.
68. Electrical applications of aluminium, sodium, &c.
69. The electrical uses of the rarer metals.
70. The treatment, testing, specifications, or uses of iron or steel, or of iron alloys, for magnetic purposes.
71. The manufacture of permanent magnets.
72. The relation of chemical composition and physical condition to the electrical or magnetic properties of substances, considered in its bearing upon electrical engineering practice.
73. High-resistance metals for instruments or resistance coils.
74. New resistance alloys.
75. The protection of laboratories and observatories against magnetic disturbances due to local causes.
76. Recent legislation in its relation to electrical undertakings.
77. The relations between electric lighting or power corporations and municipal authorities.

## PRIZE SUBJECTS OF THE PARIS SOCIÉTÉ D'ENCOURAGEMENT.

THE June number of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* contains the programme of prizes and medals proposed by the Society for 1901 and following years. The questions proposed for solution cover a large field; omitting many which have only a local interest, the chief problems suggested as prize subjects for 1901 are as follows. In Mechanics, prizes of 2000 francs for a motor weighing less than 50 kilograms per horse-power developed; for an important advance in mechanical methods of transmitting energy; and for automobiles suitable for use in towns and in the country respectively, the conditions laid down for the motor car suitable for towns requiring the absence of fumes or smell, and in the case of the one for use in the country, only such fuel to be used as can ordinarily be obtained in country towns. In Chemistry, a prize of 1000 francs for the utilisation of any waste product; of 2000 francs for a publication useful to chemical or metallurgical industry; two prizes of 500 francs each for scientific researches in chemistry, of which the results can be utilised in industrial work; a prize of 2000 francs for an improvement in the manufacture of chlorine; one of 1000 francs for the discovery of a new alloy useful in the arts; and of 2000 francs for a study of the expansion, elasticity, and tenacity of pottery clays and glazes, for a scientific study of the physical and mechanical properties of glass, for a new method of manufacturing fuming sulphuric acid and sulphur trioxide, and for the manufacture of a steel by the introduction of a foreign element possessing specially useful properties. In the Economical Arts, 2000 francs for an invention of new methods allowing of the utilisation for lighting and heating, either for domestic or industrial purposes, of petroleum, density not less than 0·800; 2000 francs for a continuous extractor; 3000 francs for a method of purifying water for domestic use; and 2000 francs for a 2-candle power incandescent electric lamp fulfilling certain special conditions.

Other prizes offered include one of 2000 francs for the best study of the diseases of cider and the means of preventing or arresting their development; of 3000 francs for the invention of a method allowing of the production of an indefinite number of positives in colours either by a direct method or with a Lippmann negative; of 2000 francs for a memoir on the silk industry in the Lyons region; of 1500 francs for a memoir on the cycle industry; and of 3000 francs for a study of commercial syndicates.

According to the general conditions for these prizes, all memoirs must be sent in before December 31, they must be written in the French language, and are open to persons of all nationalities.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

TEACHERS in Schools of Science and Technical Schools will find a Diary and Calendar just issued by Messrs. Philip Harris and Co., scientific instrument makers, Birmingham, a convenient little pocket-book. The diary is for the year commencing on September 1, and ending August 31, 1901. The dates are given of examinations in science and technology, and memoranda referring to the days on which official papers must be sent in are brought together in a calendar. The book is thus a real *vade mecum* for science teachers.

THE following Saturday morning courses for teachers have been arranged by the London Technical Education Board. A course of about ten lectures on the teaching of mathematics will be given by Prof. Hudson at King's College The object of these lectures is to help those who are practically engaged in teaching, and wish to become acquainted with modern methods and improvements in order to render their teaching more effective. A course on physics will be given under the direction of Prof. W. Grylls Adams and Mr. S. A. F. White. The course will consist of practical work in the Wheatstone Laboratory, the object of the instruction being to enable students to obtain an intimate knowledge of the methods employed in physical measurements and familiarity with the use of apparatus. A course of twenty lectures on physiology will be delivered by Prof. Halliburton. The object of the course is to acquaint teachers with the modern methods of teaching physiology by objective methods. A course of ten lectures on the teaching of physical geography, each lecture followed by a class for practical work, will be given by Miss Catherine A. Raisin, D.Sc., at Bedford College.

THE London Technical Education Board makes provision for advanced students as well as for those of elementary grades. During the coming session evening science courses will be held in connection with the Board at University College, King's College, and Bedford College. At University College, Prof. J. A. Fleming, F.R.S., will give a course of ten lectures, followed by laboratory practice, in advanced, electrical measurements. A course of lectures on the electric motor and its application in electric traction will be given by Prof. C. A. Carus-Wilson, each lecture to be followed by an experimental demonstration or by a class for the practical working of numerical examples in connection with the subject. A course will be given by Prof. E. Wilson, at King's College, on direct and alternating currents. In mechanical engineering, Prof. T. Hudson Beare will give a course of ten lectures, at University College, on the theory of steam engines and boilers, with laboratory work on the testing of steam engines and boilers. Prof. Beare will also give a course of five lectures on the theory of gas and oil engines, combined with laboratory work. A course of five lectures on water-tube boilers will be given by Mr. Leslie Robertson. A course will be delivered by Prof. D. S. Capper and Mr. H. M. Waynworth in the mechanical engineering laboratories of King's College. The course will consist of about twenty demonstrations upon steam and gas engines and general laboratory work. The latter portion of each evening will be devoted to experimental and practical work in the engineering laboratory in illustration of the lectures. A course on civil engineering will be delivered by Prof. Robinson. The methods of producing artificial cold will be the subject of a course of lectures to be delivered at University College by Dr. W. Hampton. At the same college, Mr. E. C. C. Baly will deliver eight lectures dealing with the methods of spectroscopy, especially in connection with the photography of the spectrum.

HER MAJESTY'S Commissioners for the Exhibition of 1851 have made the following appointments to Science Research Scholarships for the year 1900, on the recommendation of the authorities of the respective universities and colleges. The scholarships are of the value of 150*l*. a year, and are ordinarily tenable for two years (subject to a satisfactory report at the end of the first year) in any university at home or abroad, or in some other institution approved of by the Commissioners. The scholars are to devote themselves exclusively to study and research in some branch of science, the extension of which is important to the industries of the country. A limited number of the scholarships are renewed for a third year where it appears that the renewal is likely to result in work of scientific importance. The new scholars and their nominating institutions are as follows:—C. E Fawsitt, B.Sc. (University of Edinburgh), V. J. Blyth, M.A. (University of Glasgow), J. Moir, M.A., B.Sc. (University of Aberdeen), W. M. Varley, B.Sc. (Yorkshire College, Leeds), J. C. W. Humfrey, B.Sc. (University College, Liverpool), S. Smiles, B.Sc. (University College, London), N. Smith, B.Sc. (Owens College, Manchester), L. L. Lloyd (University College, Nottingham), Alice Laura Embleton, B.Sc. (University College of South Wales and Monmouthshire, Cardiff), J. A. Cunningham, B.A. (Royal College of Science, Dublin), W. S. Mills, B.A. (Queen's College, Galway), J. Patterson, B.A. (University of Toronto), W. C. Baker, M.A. (Queen's University, Kingston, Ontario), J. Barnes, M.A. (Dalhousie University, Halifax, Nova Scotia), J. J. E. Durack, B.A. (University of Sydney). Seventeen scholarships granted in 1898 and 1899 have been continued for a second year on receipt of a satisfactory report of work done during the first year. The names of the scholars and the places where they are studying are as follows:—J. C. Irvine, B.Sc. (University of Leipzig), H. L. Heathcote, B.Sc. (University of Leipzig), Winifred Esther Walker, B.Sc. (University College, London), F. W. Skirrow, B.Sc. (University of Leipzig), C. G. Barkla, B.Sc. (Cavendish Laboratory, Cambridge), Harriette Chick, B.Sc. (Thompson-Yates Laboratories, University College, Liverpool), F. A. Lidbury, B.Sc. (University of Leipzig), W. Campbell, B.Sc. (Royal College of Science, South Kensington), L. Lownds, B.Sc. (University of Berlin), J. T. Jenkins, B.Sc. (University of Kiel and Biological Institution, Heligoland), R. D. Abell, B.Sc. (University of Leipzig), W. Caldwell, B.A. (University of Würzburg), W. B. McLean, B.Sc. (Owens College, Manchester), B. D. Steele, B.Sc. (University of Breslau), E. J. Butler, M.B. (University of Freiburg), J. W. Mellor, B.Sc. (Owens College, Manchester), L. N. G. Filon, M.A. (King's College, Cambridge). Four scholarships granted in 1898 have been exceptionally renewed for a third year. These scholars and their places of study are:—Dr. A. H. Reginald Buller, B.Sc. (University of Munich), H. T. Calvert, B.Sc. (University of Leipzig), R. L. Wills, B.A. (Cavendish Laboratory, Cambridge), E. H. Archibald, M.Sc. (Harvard University).

## SCIENTIFIC SERIALS.

*American Journal of Mathematics*, vol. xxii. No. 3.—On continuous binary Λ linearoid groups, and the corresponding differential equations and Λ functions, by E. J. Wilczynski. In a previous paper (vol. xxi. 2) the writer has shown that, corresponding to every group of the form

$$\eta_i = \sum_{k=1}^{m} \phi_{ik}\,(x\,;\; a, \ldots a_r)\, y_k\,(1),$$

where the $r$ parameters $a_i$ are essential, there exists a system of differential equations of order $r$, whose general solutions are given by (1), if $y_1, \ldots y_n$ form a fundamental system. The functions $\phi_{ik}$ were supposed to be uniform functions of $x$, and it was found that, if the parameters $a_i$ were properly chosen, $\phi_{ik}$ were uniform functions of the parameters also. In the present paper he discusses these groups, the corresponding differential equations, and their solutions for the case when $n = 2$. Dr. Lovett, in his note on a property of lines in $n$-dimensional space, working on the lines of Cesàro's "Lezioni di Geometria Intrinseca," shows that a line of multiple curvature cuts its osculating space of highest dimensions, or lies wholly on one side of that space, according as the number of dimensions of the space necessary to the existence of the curve is odd or even.—Concerning the cyclic sub-groups of the simple group G of all linear fractional substitutions of determinant unity in two non-homogeneous variables with coefficients in an arbitrary Galois field, by Dr. L. E. Dickson (read before the Chicago section of the Mathematical Society, December 1899), leads to a generalisation to the GF[$p^n$] of results due to Prof. W. Burnside ("On a Class of Groups defined by Congruences," *Proc.* of London Math. Soc. vol. xxvi.). Variations from Burnside's method of treatment are introduced, partly to avoid the separate treatment of the cases $d=1$ and $d=3$, and to take in the exceptional cases $p=2$ and $p=3$, and to reduce the calculations; and further, on the other hand, to amplify some of the proofs. A few errors are also pointed out and amended.—On some invariant scrolls in collineations which leave a group of five points invariant, by V. Snyder. The writer gives numerous references to memoirs in which the quadric surfaces which are left invariant by cyclical collineations have been exhaustively treated. There is another simple series of scrolls, viz. those contained in a linear congruence, which have not been considered, except one form noticed by Ameseder. The writer confines his attention to such surfaces. There are six collineations which are of essentially different type, which project a set of five points into themselves without leaving every point invariant. In the notation of substitution-groups these may be thus represented:

$$\begin{gathered}
T_2 \equiv (A_1A_2)(A_3)(A_4)(A_5),\\
T_3 \equiv (A_1A_2)(A_3A_4)(A_5),\\
T_4 \equiv (A_1A_2A_3)(A_4)(A_5),\; T_5 \equiv (A_1A_2A_3)(A_4A_5),\\
T_6 \equiv (A_1A_2A_3A_4)(A_5) \text{ and } T_7 = (A_1A_2A_3A_4A_5).
\end{gathered}$$

—On the reduction of hyperelliptic integrals ($p=3$) to elliptic integrals by transformations of the second and third degrees, by W. Gilespie. The point of the paper is an application of cubic involution to the problem of the reduction to elliptic integrals, of hyperelliptic integrals of genus $p=3$ and of the first kind, by a rational transformation of the third degree. It is a continuation of Prof. Bolza's researches on the cubic transformation ("Die Cubische Involution und Dreitheilung, &c.," and "Zur Reduction Hyperelliptischer Integrals, &c.," *Math. Ann.*, Bd. 50, pp. 68 and 314).—The closing paper, by Dr. E. H. Moore, was read before the American Mathematical Society at the Buffalo meeting of the summer of 1896, and is entitled "The Cross-ratio Group of $n$! Cremona Transformations of Order $n-3$ in Flat Space of $n-3$ Dimensions."

*Bulletin of the American Mathematical Society*, July.—Some remarks on tetrahedral geometry, by Dr. Timerding, is a paper read at the June meeting. Several properties of a tetrahedral complex are given, viz. the pole curves of such a complex of lines form again another such complex among the cubic space curves circumscribed about the fundamental tetrahedron, the complex curves of such a complex of lines form another tetrahedral complex, &c.—Prof. H. B. Newson's paper on singular transformations in real projective groups was read at the April meeting. It treats of transformations in real projective groups which can not be generated from the real infinitesimal transformations of certain continuous groups. The discussion, which is limited to one and two dimensions, can be readily extended to three and higher dimensions.—Miss Schottenfels, in a paper read at the June meeting, writes on groups of order 8!/2, and gives a simple proof of a correspondence established by Dr. Dickson (*Proc.* of London Math. Soc., vol xxx.).—Prof. F. S. Woods continues his notes on Lobachevsky's geometry.—Prof. Pierpont reviews H. Burkhardt's "Functionen-theoretische Vorlesungen" (vol. ii. "Elliptische Functionen").—A "correction," notes, new publications, list of papers read before the Society, with references to the places of their publication, and a full index, complete the sixth volume of the second series.

*Annalen der Physik*, No. 7.—Dispersion of electricity in air, by J. Elster and H. Geitel. Since the sun's rays contain ultra-violet light before they impinge upon the atmosphere, this light must ionise the upper strata, and the ions produced will be gradually distributed through the whole of the atmosphere by diffusion and convection. Hence the atmosphere will contain stray ions of both signs, but chiefly negative ones in the lower strata, owing to their superior mobility. The presence of these ions can be made evident by an electroscope.—Influence of slight impurities upon the spectrum of a gas, by P. Lewis. Very small quantities of hydrogen and nitrogen considerably affect the spectra of helium and argon, but the reverse is not the case.—Fluorescence and phosphorescence in the electric discharge through nitrogen, by P. Lewis. When nitrogen prepared from ammonium nitrate and sulphate, and purified over hot copper is pumped through an H-shaped vacuum tube, the whole wall of the tube shows a brilliant fluorescence lasting a few seconds, which extends for a length of about a yard into the supply and exhaust tubes. The light can be made permanent by keeping the pump at work and thus supplying a continuous stream of fresh nitrogen. Spectroscopic examination shows that the fluorescence is dependent upon the presence of a number of bands in the extreme ultra-violet, due to a combination of nitrogen with a trace of oxygen.—Production of very high notes by Galton's whistle, by M. T. Edelmann. The author gives tables for the pitches of pipes of various dimensions, and instructions how to test the pipes by Kundt's dust figures. He has succeeded in constructing a pipe of only 2 mm. diameter, which gives the enormously high pitch of 170,000 complete vibrations per second, or over two octaves beyond the extreme limit of audibility.—The magnetic force of the atoms, by R. Lang. Magnetism is accounted for by the revolutions of negative about positive electrons.—The air thermometer at high temperatures, by L. Holborn and A. Day. The authors further investigate the properties of the air thermometer consisting of a platinum-rhodium vessel filled with nitrogen, and compare its indications with that of a platinium-iridium thermo-couple, paying particular attention to their regular expansion of the vessel. The corrected value for the melting point of gold is 1064·0° C.—Difference of temperature between the surface and the interior of a radiating body, by F. Kurlbaum. A method is given of determining this difference of temperature by means of two bolometers exposed symmetrically to different surfaces of the same black partition.

## SOCIETIES AND ACADEMIES.

### LONDON.

**Royal Society**, June 14.—"Data for the Problem of Evolution in Man. V. On the Correlation between Duration of Life and the Number of Offspring." By Miss M. Beeton, G. U. Yule, and Karl Pearson, F.R.S., University College, London.

According to the Darwinian theory of evolution the members of a community less fitted to their environment are removed by death. But this process of natural selection could not permanently modify a race if the members thus removed were able before death to propagate their species in average numbers. It then becomes an important question to ascertain how far duration of life is related to fertility. In the case of many insects death can interfere only with their single chance of offspring; they live or not for their one breeding season only. A similar statement holds good with regard to annual and biennial plants. In such cases there might still be a correlation between duration of life and fertility, but it would be of the indirect character, which we actually find in a case of men and women living beyond sixty years of age—a long life means better physique, and better physique increased fertility. On the other hand, there is a direct correlation of fertility and duration of life in the case of those animals which generally survive a number of breeding seasons, and it is this correlation which we had at first in view when investigating the influence of duration of life on fertility in man. The discovery of the indirect factor in the correlation referred to above was therefore a point of much interest. For it seems to show that the physique fittest to survive is really the physique which is in itself (and independently of the duration of life) most fecund.

The data dealt with in this paper consists of four series, the first three collected and reduced by Miss M. Beeton, and the fourth series by Mr. G. U. Yule.

### *Mothers. Length of Life and Size of Family.*

*Series I.*—Taken from the "Whitney Family of Connecticut," a well-known history of an American Quaker family.

*Series II.*—Taken from purely English Quaker records. The data for this series were drawn from a great variety of histories and records of the Society of Friends.

### *Fathers. Length of Life and Size of Family.*

*Series III.*—The great bulk of the data was extracted from the American Whitney Family.

*Series IV.*—Extracted from Burke's "Landed Gentry."

The following are some of the chief results obtained from the reduction of these series:—

*Table of General Results.*

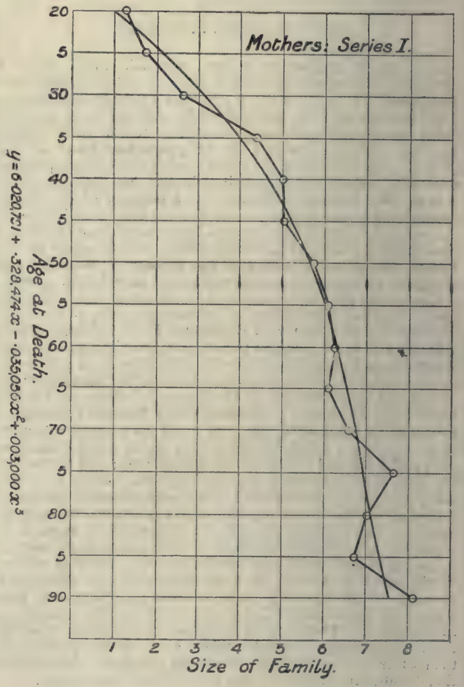
| Series. | Parent. | Mean age at death. | Mean size of family. | Correlation fertility and duration of life. |
|---|---|---|---|---|
| I. | Mother | 53·292 | 5·269 | 0·4943 |
| II. | Mother | 61·183 | 5·811 | 0·2340 |
| III. | Father | 58·086 | 5·469 | 0·4764 |
| IV. | Father | 63·577 | 5·336 | 0·2010 |

It is shown that the peculiar physique in both men and women which leads to longevity is also associated with greater fecundity. Of two women who both live beyond fifty years, the longer lived is likely to have had before fifty the larger family. The association is, however, much greater for American than English parents, although the American parents dealt with are, in the great majority of cases, of Anglo-Saxon race. Climate, mode of life, in general selection and environment, seem to be differentiating in this respect the English and the Anglo-American. The English Friends, we should suppose, would be as a class very comparable with the American Friends; yet their average life is longer, their fertility greater, and there is less association between longevity and fecundity. In both cases our algebraical formulæ show that American men and women are more alike, and English men and women are more alike than the women to the women or the men to the men of the two races. This is the more remarkable, as the English Friends as a class are by no means identical with the Landed Gentry.

In order to represent the *continuous* change in the regression, which cannot be done by two straight lines, which only enable us to distinguish the fecund and non-fecund periods of life, the statistics were fitted with cubical parabolas. The regression line at any age in life may then be looked upon as the tangent to the cubical parabola at that age. An inspection of the diagram given below for American mothers shows what an excellent expression such parabolas are for these statistics.

For American mothers and fathers we see $dy/dx$ consistently positive throughout life, and we have a most excellent graphical demonstration of the physical characters which tend to longevity being also associated with fecundity.

Weismann has suggested that it may be an advantage to a species that its duration of life should be shortened. This is not, *a priori*, confirmed by the case of a man in the American series: the longer the parents live, the greater the number of their offspring. But if we can lay any stress on a bend-in for the English mothers, and on a similar, but less marked, tendency for the English fathers, we might argue that reproductive selection was possibly in England working against extreme longevity, although favouring parents living till sixty-five or seventy. Indeed, those who rush rapidly to brilliant, but not over-stable, conclusions might emphasise Weismann's views by showing how in an old community, with much greater pressure on the material resources, there is a tendency to reduce the fertility of the long-lived parents; while in a new community, with plenty of food and occupation for all, the longest-lived parents are the most fertile! However, all that we can safely say is that there is a marked difference between English and American parents, and that this distinguishing characteristic is almost equally visible if we take opposite sexes of such diverse classes as English Friends and English country gentlemen. We would leave to further investigations its true interpretation.



Admitting a substantial correlation between length of life and fertility, it is of great interest to investigate what effect, other things being equal, reproductive selection would have in modifying the duration of life.

The following table gives the mean length of life of parents taken singly and of parents weighted with their offspring:—

*Mean Duration of Life of Parents in Years.*

| Series. | Unweighted parents. | Weighted parents. | Progression. |
|---|---|---|---|
| I. | 53·292 | 59·920 | 6·628 |
| II. | 61·183 | 63·839 | 2·656 |
| III. | 58·086 | 63·082 | 4·996 |
| IV. | 63·577 | 65·510 | 1·930 |

Now these are substantial differences even in the case of the English parents, but they are very large differences in the case of the American parents. If we suppose no assortative mating on the basis of characters tending towards longevity, then it is easy to measure by a rough approximation the effect of reproductive selection in modifying the duration of life.

The increased duration of life would be about two years per generation from the American data, and about 9 to 9·5 months per generation from the English data.

The result for the American series shows us how an especially low expectation of life, due possibly in this case to some family character, will be rapidly raised by reproductive selection, if there be no opposing factor of evolution. The English results on the other hand show us a small, but sensible, tendency in reproductive selection to prolong the duration of life. Allowing three generations to a century, we might expect the duration of life to be raised about two years in a century by this factor of evolution.

A somewhat widespread view of evolution stops at the survival of the fitter without discussing the mode whereby the less fit leave no, or fewer, offspring than the fit. Of course, if the unfit are exterminated before adult life, there is no chance of their reproducing themselves. It has been shown in "Data for the Problem of Evolution in Man (II.)" that a selective death-rate exists for adults, so that the whole work of selection does not take place before the reproductive stage is reached. But Miss Beeton's data for the correlation of duration of life in the case of brethren dying as minors seem to show that the selective death-rate for children is rather less, not greater, than its value for adults.[1] Hence, for the reduction or extermination of stock unsuited to its environment, we should have to look largely to selection in the adult state. In the present paper we have made what we believe to be the first quantitative determination of how a selective mortality reduces the numbers of the offspring of the less fit relatively to the fitter. In the case of life under wild conditions, the correlation between fertility and power of surviving would probably be far greater. But for such life it is almost impossible to get statistics of this nature; we are thrown back upon measuring the effect in man, and thus obtaining what may well be considered as a minimum value of the influence under discussion.

In the course of our investigations we have found that the relationship between fertility and duration of life does not cease with the fecund period. We thus reach the important result that characters which build up a constitution fittest to survive are also characters which encourage its fertility. This result is of great value from the standpoint of the differentiation of type, where it is absolutely necessary that the fittest to survive should also be the most fertile. On the other hand, we note that duration of life is a character capable of modification by reproductive selection, and we suggest that a considerable part of the increased expectation of life observed in recent years may be due to this cause. In the case of the American statistics, we see at once how reproductive selection can replace a remarkably short-lived stock by a longer-lived stock, for the bulk of the offspring come from the longer-lived members.

## PARIS.

**Academy of Sciences**, July 30.—M. Maurice Lévy in the chair.—On the observatory at Mount Etna, by M. J. Janssen. Remarks on local difficulties due to climatic disturbances and to the peculiar situation of the observatory.—New processes of vaccination against symptomatic carbuncle of the ox by means of preventive serum in association with vaccines, by M. S. Arloing. A continuation of former experiments on the subject.—On the age of the sea-shore sands of Dunkirk, by M. J. Gosselet. The formation of these deposits is considered to have commenced since the fourth or fifth centuries.—M. Duhem was elected a corresponding member for the section of mechanics.—Observations of Borrelly's comet (July 23, 1900) at the Paris Observatory, by M. G. Bigourdan.—Provisional elements and ephemerides of the Borrelly-Brooks' comet (July 23, 1900), calculated by M. G. Fayet.—On the spectral images of the chromosphere and protuberances obtained with the prismatic chamber, by M. Georges Meslin. A description of the results obtained with the apparatus previously described.—On two surfaces related to every Weingarten's surface, by M. A. Demoulin.—On artificial radio-active barium, by M. A. Debierne. Many substances become radio-active when brought into intimate contact, by solution or simultaneous precipitation, with radio-active compounds. Artificial radio-active barium chloride, intermediate in character between barium and radium, has thus been obtained.—On the thermo-electricity of steels, by M. G. Belloc. A comparative study of the thermo-electric properties of soft iron, soft steel, and hard steel.—On a means of weakening the influence of industrial electric currents on the terrestrial field in magnetic observatories, by M. Th. Moureaux. An account of the methods whereby the disturbances caused by electric tramways in the neighbourhood of observatories may be removed or corrected for.—On the electrolysis of concentrated solutions of hypochlorites, by M. André Brochet. The electrolysis of hypochlorite resembles, in its later stages, that of alkaline chloride solutions, and tends towards the same limits. There is, therefore, little hope of obtaining concentrated solutions of hypochlorites by the direct electrolysis of chlorides.—On gadolinium, by M. Eug. Demarçay. A study of the spectrum of gadolinium.—On diphenylcarbazide as a sensitive reagent for some metallic compounds, by M. P. Cazeneuve. The conversion of diphenylcarbazide into diphenylcarbazone by the action of salts of copper and mercury and the persalts of iron, as recently described, furnishes a delicate test for these metals. The latter unite with the carbazone to form coloured compounds.—Preliminary study of the chemism of the encephalon, by M. N. Alberto Barbieri. Experiments on the chemical changes occurring in the brain of animals when left for twelve to eighteen hours at a temperature of 45°.—On the dissolution of the nitrogenous constituents of malt, by MM. P. Petit and G. Labourasse. Experiments relating to the existence of a proteolytic enzyme in malt.—Action of the liquid from the external prostate of the hedgehog on the liquid of the seminal vesicles; nature of this action, by MM. L. Camus and E. Gley.—On some properties and reactions of the liquid from the internal prostate of the hedgehog, by MM. L. Camus and E. Gley. This and the previous paper form a continuation of the authors' researches on the coagulation of the secretion of the seminal vesicles by that of the external prostate, or Cooper's gland, and the coagulation of the latter secretion by that of the internal prostate.—On some Alpheidæ of the American coasts, by M. H. Coutière. An account of some specimens in the collection at the United States National Museum, Washington.

August 6.—M. Maurice Lévy in the chair.—The menstrual function and rut in animals. Function of arsenic in the economy, by M. Armand Gautier. The author has found that the quantities of arsenic and iodine, which in normal blood are hardly estimable, are largely increased during menstruation, the total amount of arsenic eliminated during one period of menstruation representing the whole amount usually present in the thyroid gland. The arsenic and iodine which accumulate in the thyroid gland are eliminated in the male by the hair and nails, and by epithelial desquamation. In the female, this excess is either eliminated by the genital organs or utilised by the growing fœtus.—Observations of the star Capella, considered as a double star, made at the Greenwich Observatory, by Mr. W. H. M. Christie. The independent discovery by Campbell and Newall, by spectroscopic observations, that Capella is a double star, has been confirmed by direct observation with the large Greenwich equatorial. The star appears distinctly elongated in one direction, the distance of the two components being estimated at 0·1 second. Observations of the direction of this elongation, taken between April 4 and July 20, confirm period of revolution deduced spectroscopically by Newall.—The comet (1900 *b*) discovered July 23 at the Observatory of Marseilles, by M. Borrelly. The comet is visible to the naked eye as a star of 6th to 7th magnitude.—Observations of the comet 1900 *b* (Borrelly-Brooks) made at the Observatory of Besançon, by MM. A. Sallet and P. Chofardet.—Observations of the Borrelly-Brooks comet, made at the Toulouse Observatory with the 25 cm. equatorial, by M. F. Rossard.—On circuits formed uniquely by electrolytes, by MM. Camichel and Swyngedauw. From the experiments described with circuits consisting wholly of liquid electrolytes, the authors conclude that an electrolyte may be traversed by a current without decomposition.—On the coupling up of alternators from the point of view of the harmonics, and of the effect of synchronised motors, by M. A. Perot.—On the boiling points of zinc and cadmium, by M. Daniel Berthelot. The metals were boiled in an electric furnace specially constructed to avoid the errors due to superheating and radiation from the walls, the temperature being measured by the interference refractometer method previously described by the author. Zinc boiled at 920°, and cadmium at 778°.—On the atomic weight of radiferous barium, by Mme. Curie. First attempts at determining the atomic weight of the metal in radiferous barium chloride gave 146 as against 138 for pure barium chloride. As the result of prolonged fractionations, a product has now been obtained in which the atomic weight is as high as 174. This, however, is certainly too low, as the chloride analysed still contains an unknown amount of barium.—On the electrolytic estimation of cadmium, by M. Dmitry Balachowsky. The metal is deposited upon a dish previously covered with copper. The solution is slightly acidified with nitric acid, and the deposition carried out at 60° under conditions of electromotive force and current density specified.—On some new spectra of rare earths, by M. Eug. Demarçay.—On the blue oxide of molybdenum, by M. Marcel Guichard. The hydrated blue oxide of molybdenum has been isolated in a pure state and analysed, and proved to have the composition $MoO_2.4MoO_3,6H_2O$.—On the normal proportions of iodine in the organism, and its elimination, by M. P. Bourcet. The author, in conjunction with M. Gley, having previously shown the presence of a trace of iodine in normal blood, has now determined the amount of this element in various parts of the body. The quantities found vary from 0·00 mgr. in fat, pancreas and bladder, to 0·18 mgr. per 100 grams of liver and 1·8 mgr. per 100 grams of hair. The quantities found are small compared to the amount present in the thyroid gland. About 0·33 mgr. of iodine is taken into the human system daily in food; the thyroid gland contains only about 4 mgr.; hence it becomes necessary to discover the means of elimination. This is shown to be chiefly effected in man by the skin and epidermal products, sweat, skin, hair and nails; in women, by the menstrual blood, which contains 0·8 to 0·9 mgr. of iodine per kilogram, as against 0·02 mgr. per kilogram in normal blood.—On the nitrogenous substances in malt, by MM. P. Petit and G. Labourasse.—On the origin of the secondary calcareous breccia of Ariege, and results drawn from the point of view of the age of the lherzolite, by M. A. Lacroix.—On some temperatures observed in the park of St. Maur, by M. E. Renou.

---

[1] The point is still under investigation.

### NEW SOUTH WALES.

**Royal Society**, June 6.—The President, Prof. Liversidge, F.R.S., in the chair.—On the relation, in determining the volumes of solids, whose parallel transverse sections are $n^{ic}$ functions of their position on the axis, between the position and coefficients of the section and the (positive) indices of the function, by G. H. Knibbs.—On the amyl ester of eudesmic acid occurring in eucalyptus oils, by Henry G. Smith. In a paper read before this society, July 1898, on the stringy-bark trees of New South Wales, R. T. Baker and the author show that an ester was present in the oil of *Eucalyptus macrorhyncha*. Since then esters have been found to be present in several eucalyptus oils. The author shows that esters are present in fair amount in the oils of *E. botryoides*, *E. Saligna*, and *E. rostrata*, and that an aromatic alcohol, either linalool or geraniol, is present in the oil of *E. patentinervis*, over 16 per cent. of free alcohol being proved. The saponified oil of *E. patentinervis* has a fine odour. Citral also occurs in this oil, proved by its characteristic reactions.—Note on a new meteorite from New South Wales, by R. T. Baker. The meteorite described in this paper was found early in January of this year, two miles from Bugaldi, a a postal town fifteen miles north-west of Coonabarabran. It is pear-shaped and is nearly five inches long and three inches wide at the broadest part. It belongs to that class of meteorites known as siderites, and is probably composed of iron and nickel. It has a well-defined, closely adhering "skin" of black magnetic material, while the metal immediately beneath this coating is silvery-white in appearance. On the smooth portion at the extremity of the larger end can be seen very distinctly Widmanstatten's figures. The specimen has an exceedingly new appearance, as if it had only just arrived upon the earth, and shows no signs of oxidation.

### GÖTTINGEN.

**Royal Society of Sciences.**—The *Nachrichten* (physico-mathematical section), Part i. for 1900, contains the following memoirs communicated to the Society.

February 3.—L. Krüger: Compensation of errors by means of equations of condition in geodetic determinations of points.

March 3.—E. Marx: Fall of potential and dissociation in flame-gases.—W. Nernst: On the question of the hydratation of dissolved substances, Part 1.—H. Lotmar: The same, Part 2.—C. C. Garrard and E. Oppermann: The same, Part 3.—H. Minkowski: Theory of the units in algebraic *Zahlkörper.*

March 16.—W. F. Osgood: On a theorem of Schönflies relating to the theory of the functions of two real variables.—F. Bernstein: On the same theorem.—H. E. Timerding: On linear systems of conics.

Among the official reports of the Society are one (by Prof. F. Klein) on the publication of Gauss's works; and one on the progress of the Encyclopædia of Mathematics.

THURSDAY, AUGUST 23, 1900.

## A MUSEUM CATALOGUE.

*Descriptive and Illustrated Catalogue of the Physiological Series of Comparative Anatomy contained in the Museum of the Royal College of Surgeons of England.* Vol. i. Second edition. Pp. xlix + 160. (London: Taylor and Francis, 1900.)

Of the catalogues of the Royal College of Surgeons, rendered famous by the labours of Hunter, Owen and Flower, but one in osteology, by Dr. R. Bowdler Sharpe, and one in teratology, by Mr. B. Thompson Lowne, have appeared during the present conservator's term of office. Prof. Charles Stewart, unlike his predecessor in this office, who concentrated his attention upon one special department, has since his appointment greatly developed all sides of the collection, and with the aid of his competent assistants has added year by year specimens of surpassing value and interest, which have become the admiration of all beholders. The period of his conservatorship has been one of unparaleled activity in all branches of zoology, and in the labour of keeping pace with this he has not been found wanting, as, for example, when, on the discovery of the calcified teeth of the Monotreme, he produced from his rich store of material the famous specimen which has since adorned his shelves, and shows more than all others yet described. With this museum, as with others in our own land, the Englishmen's colonising instinct has come forcibly into play, in the accumulation of objects, not merely of local interest, such as are generally to be found in the museums of other countries, but general and universal, wherefore the present catalogue is of necessity based upon a matchless material.

It is explained in the preface that the specimens registered have been dealt with on the original Hunterian lines, the intention being to bring together examples of such structures in plants and animals as perform the same function; and comment is further made upon the necessity for a large number of preparations "to supply the places of those that have become worthless, and to serve as illustrations of new discoveries, and phases of thought." At the outset, necessity, begotten of progress and advancement, is met by the propounding of a scheme, clearly explained in the text, under which it is proposed to distinguish, firstly, between "Structures concerned in the preservation of the individual or to its advantage" and those "concerned in the preservation of the race." Under the former of these departments, sixteen headings are included, under the latter eight; and since the present catalogue deals with but the first three of the former series, those alone need be further remarked upon. They read "Endoskeleton"; "Flexible Bonds of Union and Support"; "Muscular and Allied Systems"; but before passing on to consider them more fully, it may be said that they and the twenty-one headings of sections to follow are, in the preliminary portion of this, the first volume of a series, individually set out in greater detail, each with a concise statement of the order of arrangement to be adopted, and a definition, when necessary, of what is implied in the heading it bears.

The arrangement of each section is so framed as to include both plants and animals, whenever possible, the former being considered first, and each in ascending order. Turning now to the three sections to be specifically considered, we find specimens illustrating, under the first, the chemical composition, structure, and mode of formation of the various endoskeletal systems; under the second, the various forms of ligaments and joints; and under the third, the forms, structure and texture of muscles. To particularise in these columns concerning the details of either of these is impossible; but it may be said that no leading type of tissue or arrangement of parts is unrepresented, and that preparations like that of the cartilages of the cuttle, the elastic honeycomb of the flexor carpi muscle of the elephant, or of the leaves of the sensitive plant fixed in the diurnal position, must be seen to be appreciated.

The most attractive portions of the work are those dealing with the marvellous array of processes occurring in the growth of the coral skeleton, and (as pertaining to the study of joints and jointing) with the question of adaptation in these to the conditions of existence. The study of the general question of origin, detailed constitution and relationship, of the coral skeleton, has for years engrossed the attention of Prof. Stewart; and to our knowledge of this subject and the allied one of the structural variations of the bony tissues of the osseous fishes, he has in the long run added more than most other investigators since von Kölliker. Beyond laying this magnificent result of his labours before audiences which annually assemble on the occasion of lectures delivered in his official capacity, and occasional "exhibits" before the Linnean and Zoological Societies, he, with a modesty so marked as to be well-nigh depreciative of his talents, has published nothing concerning them; and the present volume therefore comes rather as a memoir from his hands than as a mere official catalogue, and it is worth all the scattered papers he could have published in the time. It teems with interest and records of beautiful objects, and is illustrated by fourteen magnificent plates, mostly in colour, done from his own drawings by the facile hand of Green, than whom no better English lithographer in zoology exists. Of these plates no praise can be too high, and we expect for them an unprecedented popularity in the future. They must be seen to be appreciated, and, with the exquisite preparations they illustrate, constitute a possession of which even the Royal College of Surgeons may well be proud. Each of the entries in the catalogue bears a registration number, and where desirable a short bibliográphic reference, as an aid to the student.

The success of this volume augurs well for the future of the museum and its collections, and knowing the unparalleled excellence of the numerous additions which during the last decade have been made to the series of which it treats, thanks to the curatorial genius of Prof. Stewart and the unrivalled skill of his lieutenant, Mr. R. H. Burne, we can safely predict even a better result for the volumes yet to come. The collection of zootomical preparations arising under their hands is far and away the best in existence, and together with the governors of the college they have ensured a debt of gratitude which it will take generations to repay.

In the pages of this volume the student will find records of structures and relationships undreamt of in the text-books, unrecorded in the best monographs; and it is a pity that he is not informed of this. The work is a positive storehouse of new facts and intensely interesting details, and will be of inestimable value to zoologists at large.

---

## *A TEXT-BOOK OF MAMMALS.*

*Text-book of Zoology, treated from a Biological Standpoint.* Part I., Mammals. By O. Schmeil. Translated by R. Rosenstock, and edited by J. T. Cunningham. 8vo. Pp. vii + 138, illustrated. (London: A. and C. Black, 1900.)

AS stated in the first title-page, this book is intended for the use of schools or colleges, forming, in fact, a portion of the series of School Text-books now in course of issue by the publishers. It is, therefore, essential that it should be written in a popular and attractive style, and also that it should be absolutely accurate and up-to-date, both as regards the facts recorded, and, so far as possible, in nomenclature. So far as this first item is concerned, the present fasciculus appears to fulfil the required conditions fairly well, the anatomical details being treated in a manner which renders them of easy apprehension by the student, while the descriptions of the animals themselves are, if anything, written in a too popular style. The plan adopted is to take a more or less typical member of a group for special treatment, and then to refer to the kindred forms in a more general manner. Illustrations are numerous; and while many of them are excellent, others, especially the cut of a family of orangs on p. 19, can only be described as hideous caricatures. In a book written primarily for German students, it must be inevitable that the animals of the Fatherland come in for a fuller share of notice than would have been the case had it been the product of an English author, but this is a fault of no special importance.

When, however, we come to the second essential feature of an elementary text-book—accuracy as regards facts, classification and nomenclature—we are bound to confess that the fasciculus before us fails lamentably. Indeed, its appearance is almost a calamity for zoological science in England, since the student who intends to pursue the subject seriously will have much to unlearn; and even for those who only desire a smattering of the subject, it is most important that they should become acquainted with animals by their proper titles, and that what they are taught as facts should really be such. In his preface the editor tells us that he has practically restricted his task to comparing the translation with the original, correcting the proofs, making here and there emendations in detail where a statement seemed open to doubt, or where differences between the faunas of Britain and Germany had to be indicated. For the sake of his own reputation it is a pity that he did not compare the work in detail with a standard English treatise on mammals, when he could scarcely have failed to detect some of the shortcomings of the original text, despite the fact that all the English treatises on the subject are now more or less out of date.

As regards the general classification of the group, although this differs to a certain extent from the one generally adopted in this country, we have no comment to make, except that for some unaccountable reason the order Sirenia is totally omitted, while there appears to be no mention of the animals by which it is represented anywhere in the text!

Turning to some of the ordinal groups, we find the orang taken as a typical representative of the apes, and rightly named *Simia satyrus*. Naturalists will, however, be considerably surprised to see the chimpanzee (p. 22) assigned to the same genus (*Simia*), whereas the gorilla is made the type of a genus by itself; since if there is one well-established zoological fact, it is the intimate relationship existing between the chimpanzee and the gorilla, and the wide gulf separating both from the orang. Again, under the heading of the Platyrrhine apes, there is no reference to the marmosets, and we quite fail to find a reason for the statement (p. 22) that the howling monkeys are the best known members of that group. In treating of the Lemuroids, the author departs from his rule of selecting one species for special notice, and the space allotted to the group is ludicrously inadequate.

As an instance of careless writing we may refer to the notice of the tiger (p. 33), when, after stating that this animal is found in Amurland and Central Asia, the anthor proceeds to say that its "favourite haunts are swampy districts of the tropical zone, thickly overgrown with bamboo and similar bushes." Again, on p. 84 we find *Cricetus frumentarius* alluded to as "the marmot or hamster," although the true marmots are noticed in an earlier page. Passing on to p. 105, we meet with the statement that the Indian buffalo is *said* to exist in a wild state in the "East Indies"; while the European bison is stated to be extinct, although on an earlier page (98) its existence in Lithuania and the Caucasus is alluded to! Although we do not propose to notice in detail the hopelessly obsolete generic and specific nomenclature adopted, the statement on p. 106 that "the best-known African antelope is the gazelle (*Antilope dorcas*)" is, however, too ludicrously absurd and incorrect to be passed over. And as a second instance of incorrect nomenclature we may refer to the inclusion of the roe (p. 108) in the same genus as the red deer, from which the fallow deer is excluded. And in this connection it may be mentioned that the editor, who has been recently writing on deer antlers, should have been aware that the brow-tine is not developed in those of the roe.

Before leaving the Placentals, it may be mentioned that the practice of reckoning the carnassial teeth of the land Carnivora as distinct alike from the molar and premolar series is not calculated to give the student an idea of the homology of the cheek-teeth throughout the class. And we also venture to think that the statement on page 37, that "in its dentition the wolf very nearly resembles the cat," in spite of the subsequent qualification that the number of teeth is greater, scarcely accords with the facts.

In the definition of the Marsupials, exception must be taken to the statement that the young are *always* nourished in a pouch; and when mentioning the occurrence of the group in America no reference is made to *Cænolestes.* Indeed, the account of the whole group is entirely inadequate; and when the author speaks of the value of American opossum fur, we strongly suspect he had in his mind the product of the so-called opossums of Australia.

Finally, when treating of the Monotremes, the author states that the spiny anteaters are represented solely by *Echidna hystrix* and *E. setosa.* As a matter of fact, these two forms are but local races of a single species whose name is *E. aculeata*; and the author appears to be totally unacquainted with the very distinct genus commonly known as *Proechidna!*

As already said, we do not intend to criticise in detail the nomenclature employed; but in the retention of names now discarded by those who have made a special study of the class the author has done his best to put his work out of touch with the present state of science.

In making this statement, we are aware that the author lays stress on the circumstance that he is treating his subject from a biological standpoint. This, however, in our opinion, is no excuse for neglect of the details o classification and nomenclature.

When treating of the adaptation of animals to their environment, the author is always interesting; and the paragraphs devoted to this part of the subject are, to our mind, the best in the whole fasciculus. R. L.

## GOOD AND BAD AIR.

*The Carbonic Anhydride of the Atmosphere.* By Prof. E. A. Letts, D.Sc., Ph.D., and R. F. Blake, F.I.C., F.C.S., "Scientific Proceedings of the Royal Dublin Society," vol. ix. (N. S.), Part ii. No. 15. Pp. 270. (Dublin: 1900.)

*The Air of Rooms.* By Francis Jones, F.R.S.E., F.C.S. Pp. 59. (Manchester: Taylor, Garnett, Evans and Co., 1900.)

THE first of these pamphlets would amply justify its publication, if it only served to emphasise the necessity of further investigation into the methods of estimating carbon dioxide in the atmosphere. It is partly experimental, partly bibliographical in character. The authors, finding themselves called upon to make a series of observations on the carbon dioxide of the air, have made a careful study of Pettenkofer's method, and have introduced some necessary corrections, without detracting very much from its simplicity. They take the precaution, suggested by other observers, of preventing the action of the baryta solution on the glass by coating the vessel with a layer of paraffin wax. It may be pointed out that a solution in benzene is more suitable than the melted wax. The thinner film obtained with the solution is less liable to crack. The baryta solution is manipulated very ingeniously out of contact with air. Yet with all these precautions the results show that perfection is far from being attained.

In the set of analyses on page 132 there is a discrepancy between the highest and lowest figures of 10 per cent.; in another set on the same page the difference amounts to 17 per cent., and on the next page to 20 per cent.

It seems superfluous to introduce the third decimal into the result when the experimental error affects the first decimal place, and equally unnecessary to make a correction for aqueous vapour, which only amounts to about one and a half per cent. on the volume of carbon dioxide, as against 10 per cent. or thereabouts from experimental error.

The authors omit to mention how long the baryta remains in contact with the sample of air. This is an important factor which should not be neglected, for there can be no doubt that the absorption of carbon dioxide by the baryta proceeds at a rapidly decreasing rate and that the final traces of the gas may take many hours to disappear.

The book is full of useful information, drawn from a variety of sources, the collection of which must have cost the authors no little trouble. At the same time, one is inclined to think that the value of the information would have been enhanced if they had gone another step and made a critical selection from the mass of analyses which they reproduce, for the figures cannot all be equally trustworthy, and many of them must be entirely illusive.

The second pamphlet relates to domestic hygiene. It treats of the effects produced on the air of rooms by the use of gas, coal and electric light for heating and lighting purposes. The effect is determined by estimating the amount of carbon dioxide by Pettenkofer's method, and by exposing a layer of permanganate solution to the air and finding the quantity of the salt reduced.

Mr. Jones, unlike the authors of the previous pamphlet, is not troubled by misgivings about Pettenkofer's method, except in the matter of the baryta attacking the glass. He therefore substitutes lime-water as the absorbent, apparently unaware of the fact that its effect on glass is precisely of the same character, which may be easily observed by placing very dilute lime-water coloured with phenolphthalein in any glass vessel; in a day or two the colour will be completely discharged. As the results here are only required for comparison, great accuracy is not requisite, and the ordinary method may be relied on. The results of the permanganate method will scarcely serve to recommend it. We find, for example, that in two experiments made on July 21 two-thirds the quantity of permanganate was reduced in the one case in double the time. As Mr. Jones points out, the quantity of dust may affect the rapidity of reduction. If this is the case, effective ventilation will produce disturbance of the air and movement of dust as well as local currents from gas-jets, and it will be difficult to differentiate the two. The results which Mr. Jones obtains are precisely what might be anticipated if we take into account the fact that a coal fire produces an enormous air current through a room near the floor level, whereas a gas fire usually only serves to carry away its own products of combustion. Mr. Jones finds that the purest atmosphere is maintained with a coal fire and electric light; then follow gas fire with electric light, coal fire and gas light, and gas fire and gas light. The worst effect is produced by an open gas cooking stove without flue. The author shows, moreover, that gas light is more deleterious than a gas fire. That the worst atmosphere exists at the top of a room where the heated products of combustion accumulate is only natural. That is the reason, it is to be presumed, why the topsy-turvy method of ventilating at the floor level with a coal fire is the one most generally in use.

## OUR BOOK SHELF.

*Lamarckiens et Darwiniens; Discussion de quelques Théories sur la Formation des Espèces.* Par Félix Le Dantec, Chargé du Cours d'Embryologie générale à la Sorbonne. Pp. 191. (Paris: Félix Alcan, 1899.)

THIS is a well-intended, but scarcely adequate, endeavour to reconcile the Darwinian with the Lamarckian conception of evolution. While admitting the principle of natural selection as an important factor in organic development, the author seeks to explain the origin of species mainly on a Lamarckian basis. It may be doubted whether his suggested compromise will commend itself to either party. We are of opinion, *pace* M. Le Dantec, that Darwin's estimate of Lamarck was perfectly just; and that if Lamarckian views are to prevail, it must be by dint of facts and arguments other than those adduced by Lamarck himself. The present volume contains nothing approaching a demonstration of the inheritance of acquired characters; and until this is forthcoming, the Lamarckian fabric must be held to lack foundation. It is curious that the author, who has undoubtedly grasped the principle of natural selection, should not see how groundless is his hesitation in applying it. A reason for this failure is doubtless to be found in his tendency to deal with cases of adaptation as if they were ready made; he has apparently not taken into account the evidence of gradual approximation to the completely adapted condition. How, he asks, can chance have produced the aspect of *Kallima*? A study of allied forms might have shown him that his question was wide of the mark. On the crucial subject of mimicry and protective resemblance, this strange reluctance to carry an admitted principle to its legitimate end produces especially unfortunate results. M. Le Dantec is constrained, not only to suppose that the white of Arctic animals may be a direct result of the colour of their surroundings "as in Poulton's experiments on caterpillars," but to assume the conscious adoption of appropriate habits on the part of protected organisms. It would seem that not much is here gained by the abandonment of the Darwinian standpoint. In the last few chapters of the book the author expounds his "biochemical" theory of heredity, but without throwing any new light on the familiar difficulties of the subject. It is open to any one to proclaim his faith in the essentially chemical character of all kinds of protoplasmic activity, but the fact remains that among these phenomena there is a residuum which does not easily relate itself with what is known of the properties of other kinds of matter. This is where the problem was found by M. Le Dantec, and this is where he has left it.

*Helen Keller: Souvenir.* Pp. 65. (Washington: Volta Bureau, 1899.)

THE achievements of Miss Helen Keller bear striking testimony to what it is possible to accomplish in the education of the deaf. Though totally blind, as well as deaf, from infancy, she succeeded in passing the examination for admission into Radcliffe College, Harvard University, a year ago. In honour of this remarkable result, the Volta Bureau, which exists for the increase and diffusion of knowledge relating to the deaf, has published this souvenir, containing an account of her career, contributed by Dr. A. Graham Bell, Miss A. M. Sullivan and other instructors, and herself.

Dr. Bell considers that the lesson taught by Miss Keller's case is that books should be used at the earliest stages of a deaf or blind child's education. "I would have a deaf child read books in order to learn the language," he remarks, "instead of learning the language in order to read books." Miss Sullivan describes how she gave Miss Keller books printed in raised letters long before her pupil could read them. Words of particular shapes were associated with particular objects and actions, and in a comparatively short time Miss Keller thus acquired an exceptional knowledge of the English language.

Miss Sullivan employed the manual alphabet exclusively as a means of communication at the commencement of the child's education. She adopted the method of talking to Miss Keller just as she would to a seeing and hearing child, spelling into her hands the words and sentences she would have spoken to her if she could have heard, in spite of the fact that at first much of the language was unintelligible to the child. Three years after beginning to communicate by means of the manual alphabet, Miss Keller began to try to imitate sounds. Some deaf children are taught to speak by imitating the movements of the lips of the teacher. Miss Keller could not see these movements, but she could feel them by touching her teacher's lips, and she was soon able to reproduce the same sounds and articulate words.

How Miss Keller was prepared for admission into Radcliffe College, the entrance examination of which is exactly the same as that of Harvard College, is described by her instructors, and Miss Keller gives a simple chronological account of her studies. The whole statement is a remarkable narrative, and will be of the deepest interest to teachers of the deaf and students of psychological development.

*The Psychology of Reasoning.* By Alfred Binet. Translated by Adam Gowans Whyte. Pp. 191. (Chicago: Open Court Publishing Company. London: Kegan Paul and Co., Ltd., 1899.)

THIS is a translation of the second edition of M. Binet's well-known book, the main object of which is to show the essential similarity of perception and reasoning, and to illustrate the nature of the latter by our more complete knowledge of the former, especially with reference to the part played in perception by mental images. When the "Psychologie du raisonnement" first appeared, the more or less novel facts about mental imagery discovered by Galton and Charcot were described in a clear and interesting manner, and this feature remains without alteration. In fact no appreciable alterations have been made in the present edition, even when called for; thus Parinaud's evidence in favour of the central seat of after-images is repeated, although generally acknowledged to rest on a misconception of the relations between the two eyes. The book is full of interesting psychological facts; but unfortunately most of these are drawn from hypnotic experiments, and Binet does not yet appear to have recognised that, owing to the influence of unconscious suggestion, it is very dangerous to found psychological theories on such a basis.

Nevertheless M. Binet's work should be very welcome in an English form, and this the more so that the translation has been very well done.

*Electric Batteries: How to Make and Use Them.* Edited by P. Marshall. Pp. 63. (London: Dawbarn and Ward.)

THE principal forms of primary electric batteries are described in this little book, and some serviceable details are given concerning their working and use. The book will be particularly helpful by amateur electricians; and students of electricity will find in it some information not usually given in the text-books.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Snow-drifts on Ingleborough in July.

ON July 4 last I was on Ingleborough with a party of geologists examining the swallow-holes which mark where the water, running off the impervious drift and shale above Newby Moss on the southern shoulder of the hill, first reaches the Mountain Limestone. Some of these swallow-holes are what we may call obsolete—that is to say, when new openings have been formed and enlarged as time went on, some of the chasms which obviously at one time carried off the flood-water from a large gathering-ground, now receive only what oozes in from the peat and drift immediately round it, or the rain which falls directly on it: and rain seldom falls vertically up there. Some of them seem to have been developed without any large body of water having ever invaded them. They run to great depths, the open shaft being from 30 to 360 feet deep, below which the cavernous rock carries the water on through caves and crevices and open joints far down to the valley below.

In one of the vertical caves, which lies east of Long Kin and runs down into the limestone rock to a depth of some 70 feet, there were masses of snow to 4 feet in thickness. It was speckled brown on the surface, from the particles of peat which had been blown on to it, but was pure and white within. Obviously the chasm had been filled by drifted snow during the winter, and the summer's sun could not reach that depth to melt it, while the earth temperature was lost on the moist pinnacled rock on which it rested. No flood ever filled this particular chasm with a swirling torrent, such as at times fills Weathercote Cave, Hunt Pot, or even Gaping Ghyll up to the brim, and causes them to overflow.

Here, therefore, we had an accidental combination of conditions favourable for the preservation of snow, long past midsummer, at a height of not more than 1500 feet above the sea, on the flank of a Yorkshire mountain.

This is an interesting fact to bear in mind when speculating upon the causes of glacial conditions having so recently prevailed over the British Isles. We see here that half-way up Ingleborough, in an exceptionally hot summer, the air temperature alone could not remove last winter's snow.

T. MCKENNY HUGHES.

### The Total Eclipse of the Sun of May 17-18, 1901.

IN the *Nautical Almanac Circular* (No. 18) local particulars of this eclipse are given for four places in the eastern portion of the shadow track, three of which, Padang, Pontianak and Amboyna, are situated in Netherlands India. In the explanations it is mentioned that, from inquiries which have been made, it appears that the positions selected are the most accessible, and that it would probably be impossible for observers to occupy any neighbouring station for which the astronomical conditions might be more favourable.

Surely these inquiries have not been made on the spot, where the information could best have been obtained. Other localities in the Government of Sumatra's west coast are as easily accessible as Padang, from which a railway leads to the interior; and other localities on the banks of the Kapuas as easily as Pontianak. Moreover, many other places may give opportunity to eclipse parties for observation, viz. on the islands of Lingga and Singkep, on the banks of the Barito and the eastern coast of Borneo, in the Gulf of Tomini (Celebes) and in the Moluccas. The conditions, however, will be most favourable in the western part of the Archipelago, both on account of the longer duration of totality and also for local resources. Through the Koninhlijhe Natuurkundige Veruniging at Batavia, data have been gathered referring to the conditions of weather and cloudiness at a number of stations most suitable for the observation of the eclipse, and the data will be published in due time. The general impression is, however, that the chance for fine weather is nowhere very great. The Society will be pleased to procure full information as to the choice of stations, and observers may be sure to receive every available assistance from the local authorities and officials in the Dutch colonies.

J. J. A. MULLER.

(President of the Kon. Natuurk. Ver., Batavia, July 17).

### The Reform of Mathematical Teaching.

MANY schoolmasters tell us that boy-nature is so depraved that his time must be fully occupied, and that a "regular hard grind" is the only way to keep him out of mischief. They give him things to grind that do not interest him; it may be that he does not understand them, or that they have no human interest. And yet every boy has interests, and teaching directed towards those interests would enthral him. The first aim should be to attract the boy's attention, and a subject which no excellence of teaching will make interesting to a particular boy is no fit subject of study for him.

The case of mathematics is bad. The reasoning is too abstract for a boy's mind, but it has worse faults. Long strings of reasoning are employed to deduce fairly obvious conclusions from premises no more obvious, *e.g.* in the theory of parallels. On the other hand, incorrect proofs are given because the boy cannot grasp correct proofs, *e.g.* for the binomial theorem. Geometry is in worse case than algebra. Euclid's interest was logical rather than geometrical; he wished rather to put together a consistent series of syllogisms than to give the best solution of his problems: witness his bisection of a straight line. In consequence, the natural order of development is lost sight of. A boy ought to be at home with ruler and compasses before he reasons about the constructions possible with them, and yet most schoolboys have never handled compasses. A few weeks ago I asked some hundred boys in a well-taught school (as present teaching goes) to give a certain construction of Euclid's, and also to carry out the construction with ruler and compasses on a given line. Hardly one failed to write out the construction and proof, but only one of the hundred carried out the practical construction. Clearly our present Euclidian teaching has little to do with geometry.

To lay before a boy a proof he does not understand is useless, to prove the obvious is confusing, to give an incorrect proof is immoral. Prof. Perry's plan to abolish proofs in the early stages is a great step in advance of present teaching. For the boy of mathematical ability it would perhaps be well to run theory alongside, at the rate of five or six propositions for Euclid's entire first book. This would, however, interfere with class teaching, and the mathematical boy would lose little by going through a good deal of the practical course before touching theory; if with a hint here and there he could be got to evolve the theory for himself, he would gain much.

Possibly a theoretical training leads one to look with too favourable an eye on early theory. In any case, that in the hands of a good teacher theory and practice could well go hand in hand for boys even of average ability is shown by two able papers by Mr. Branford, in the *Journal of Education*, on the first teaching of geometry. We may finally reach this stage, but till we have these good teachers practice should precede theory.

DAVID MAIR.

### Functions of an Organ of the Larva of the Puss Moth.

THIS season I am breeding, with the object of observing their gradual growth and development, a number of the larvæ of *Cerura* (or *Dicranura*) *vinula*, the Puss Moth; but I have sought in vain for the function performed by the slender red filaments, ejected, at the insect's will, from its twin tails. They appear to shoot from their sheathes, just on the same principle as do a cat's claws; but to what purpose?

Surely such a beautiful, delicate organism could not have been appointed to no purpose! Is this merely an instance of entomic mimicry, simulating, for its own protection, the sting of some venomous insect; or does this strange organ perform some practical, active function?

I shall be very greatly obliged if you can tell me whether this point has been already decided or not, and, in the latter case, perhaps some of your correspondents will kindly communicate their views upon it. ARTHUR S. THORN.

4 Malcolm Road, Penge, August 10.

### Dark Images of Photographed Lightning Discharges.

A VERY clear illustration of the reason why some of the lightning discharges in a photographed thunderstorm appear dark was afforded me at Wednesfield, Staffordshire, about mid-day on Thursday, July 19. There were a number of double flashes, that is, two discharges occurring rapidly in the same apparent region, but following different courses, and separated in time by from one-eighth to one-half of a second. But one flash, quite near to where I stood (one second and a half between flash and sound), gave a repetition following absolutely the same path as the first flash and practically as bright. The only difference was that two faint branches of the first flash were not repeated in the second discharge. The second flash followed so quickly (about an eighth of a second, I estimate), that the impression on the retina of the first discharge had not died out when the second exactly covered it, so that I could appreciate the absolute coincidence. A few kinematographic records of thunderstorms would show whether or not such repetitions are common, and whether they are the cause of dark flashes on the photographic plate.

Cave Castle, Dumbartonshire, N.B. J. B. HANNAY.

## *THE LAVOISIER MONUMENT.*

THE monument erected by international subscription in honour of Lavoisier was unveiled on July 27, in the presence of M. Leygues, French Minister of Public Instruction, and many eminent men of science, including most of the members of the International Congress of Chemistry. The committee entrusted with the raising of the fund for the statue succeeded in obtaining a sum of 100,000 francs, which was subscribed by admirers of Lavoisier in most parts of the civilised world. M. Moissan was the secretary of the committee, and he acknowledged at the unveiling ceremony that there had not been the slightest difficulty in obtaining the means to erect the monument—many subscribers, indeed, were astonished to learn that Paris, where monuments abound, did not possess a statue of the eminent chemist whose investigations helped to lay the foundations of modern chemistry. It is true that appreciation of the great chemist has been shown by the publication of his complete works, but these are only known to a limited number of students, and the people who live in the present are likely to forget how much they owe to the past unless they are reminded of their indebtedness by some striking monument in bronze or stone. For this reason, it is well that a permanent memorial of Lavoisier's greatness has now been erected.

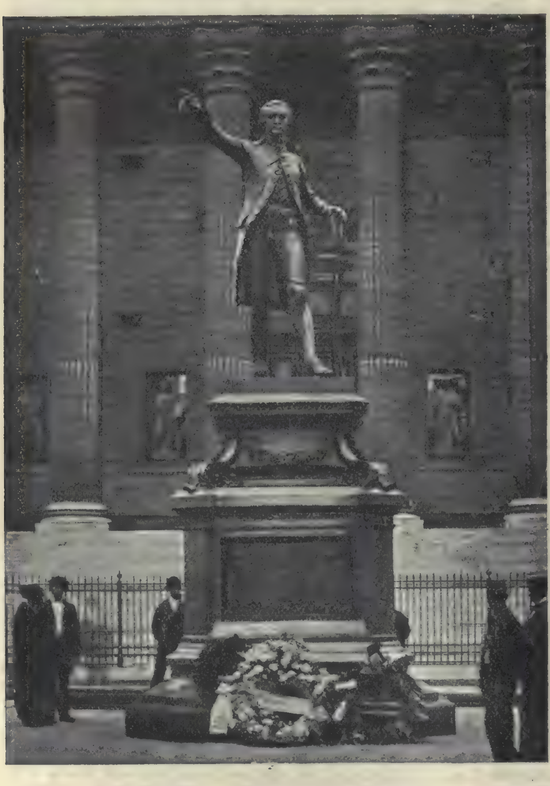

FIG. 1.—The statue of Lavoisier.

The statue, which is represented in the accompanying illustration from *La Nature*, is erected in the open space behind the Madeleine Church, close to the house where Lavoisier lived for some years. It is of bronze, and stands upon a granite pedestal ornamented with bas-reliefs. The statue is by M. Barrais, and the pedestal is due to M. Gerhardt. Upon the front of the statue the following inscription appears, in French, "Antoine Laurent Lavoisier, 1743–1794, founder of modern chemistry. Erected by public subscription, under the patronage of the Academy of Sciences. M. Berthelot, Permanent Secretary of Physical Sciences, 1900." One of the bas-reliefs represents Lavoisier explaining his discovery of the composition of air to his colleagues of the Academy of Sciences, of which he was president, the characters introduced into the scene being Monge, Lagrange, Condorcet, Berthollet, Vicq d'Azyr, Laplace, Lamarc and Guyton de Morveau. On the other bas-relief Lavoisier is shown in his laboratory dictating notes to his wife. The statue appears to be a real work of art, worthy of the sculptor and of the subject.

M. Berthelot was to have presided at the ceremony of the unveiling, but illness prevented him from being present, and his address was read by M. Darboux.

Reference was made to the fact that the inauguration took place under the auspices of the Institute of France, the City of Paris and the French Government, and stress was laid upon the truly international character of the homage to the genius of Lavoisier, as testified by the subscriptions. The following is a free translation of parts of the address:—

> The names of Galileo, Newton, Leibnitz and Lavoisier show that science has no nationality, a monopoly of pure or applied science being the property of no one nation. The erection of a statue in a public place is an honour usually reserved for statesmen and warriors, men who have spattered the earth with blood, too often without lasting profit to the nation devoted to them. To-day the famous savant, thinker, artist, is put in the first rank by enlightened people, and posterity will doubtless continue to show an increasing respect for the memory of those men who have served the human race, and to relegate to obscurity the men of blood and intrigue who have enslaved it.
>
> The work of Lavoisier is epoch-making from two points of view, from that of philosophy, because he established the fundamental law which governs the chemical transformations of matter, and from the practical point of view, because this law has become the base of innumerable industries founded on these transformations, and the origin of the rules of hygiene and therapeutics which follow from it. The fundamental discovery of Lavoisier was the distinction between matter and the imponderable agents, such as heat, light, electricity, which

influence it. The discovery of this distinction overthrew all the old ideas dating from antiquity, and which continued up to the end of the last century. According to the ideas which were current when Lavoisier started his work, there were four elements—earth, air, fire and water—from which all substances existing in nature were said to be built up. By associating these elements in different proportions and by different methods, it ought to be possible to produce all bodies and transform any one into any other. As a matter of fact, the prolonged researches of serious workers had never succeeded in establishing this transformation, nor has this been accomplished since. But preformed ideas are tenacious, especially when supported by mysticism.

An equally grave mistake was committed in supposing that bodies submitted to the influence of heat alone could vary in weight, a variation apparently proved by innumerable observations with the balance in chemistry. It is, in fact, a most singular error, although one frequently held, that the use of the balance in chemistry dates only from the end of the last century. In reality its use is sixteen centuries old. The balance was used both in chemistry and in trade; it may be seen represented on the monuments of ancient Egypt. Bodies such as coal, oils and organic substances under the action of heat were known to lose their weight, hence was drawn the conclusion that matter may be transformed into heat and disappear; whilst heat, on the other hand, under inverse conditions, could be fixed, becoming visible ponderable matter. These opinions gave way to the views of Stahl, according to whom combustible bodies were rich in phlogiston, or fixed heat. Such was the state of science about 1772, when Lavoisier appeared on the scene. Ten years were sufficient for him to effect a complete transformation. He established, by the most precise experiments, a fundamental distinction, previously unknown, between the nature of bodies which we know, and heat and other agents capable of modifying these; it is the distinction between ponderable bodies and the imponderable heat, light, electricity, the intervention of which causes no change of weight in ponderable matter.

It could hardly have been expected that one man alone should make all the researches establishing the properties of gases, the composition of air and of hot water, and in this respect there can be no doubt that Lavoisier profited by the partial work of his predecessors and of contemporary workers; but to him alone belongs the merit of demonstrating the connecting links, and of giving the facts their true interpretation.

Two fundamental problems were first attacked by Lavoisier, the gain in weight of metals on calcination, and the apparent loss of weight of carbon, sulphur and oils on combustion. His first discovery was to put these phenomena upon a proper experimental basis. He demonstrated that in all such cases a weighable substance contained in the air takes part in the change, the addition of which explains the increase of weight of the calcined metals, an increase equal to the loss of weight sustained by the air. The same ponderable element in the air was shown to take part in the burning of carbon, sulphur and oils, forming gaseous compounds, the weight of which was also determined by Lavoisier. It was thus established, what had never been done before, that the materials of bodies possessing weight kept this weight constant throughout a series of chemical changes, heat and other agents of the same order having no effect either in increasing or decreasing the weight of the original bodies. This fundamental distinction between ponderable matter and imponderable agents is one of the greatest discoveries that has ever been made; it lies at the base of physical, chemical and mechanical science. Lavoisier, however, went farther than this, and attempted to penetrate the constitution of ponderable matter itself. He recognised that in all known experiments it presents itself as constituted by a certain number of undecomposable elements or simple bodies, which, combining amongst themselves, form all known compounds.

The two fundamental laws of nature once established—the distinction between matter and imponderable agents, and the invariability of the nature and weight of the simple bodies—Lavoisier went on to draw important conclusions on the composition of the acids and metallic oxides, the composition of air, water and organic substances, on the *rôle* of heat in chemistry, on animal heat and on the nature of respiration in physiology.

What share ought to be now attributed to Lavoisier in the classical discovery of the compound nature of air and water, a discovery in which he competed with Priestley and Cavendish? The matter would take too long to give here in detail. Suffice it to say that he alone swept from the composition of air and water the erroneous notion of phlogiston maintained by his contemporaries.

All these discoveries, accumulated in the course of only a dozen years, and carried out with wonderful ardour and energy, were not simple proofs of isolated facts; on the contrary, they were the consequences logically deduced and experimentally demonstrated of the two fundamental laws due to the genius of Lavoisier. The physiological questions relating to respiration were also answered completely and successfully; given a correct knowledge of the elementary composition of carbonic acid, of food materials and of air, respiration was then obviously a slow combustion of food by the oxygen of the air, a combustion producing carbonic acid and developing at the same time sufficient heat to maintain the human body at a nearly constant temperature.

A complete account of the after effect of Lavoisier's work would require almost a history of physical science during the nineteenth century; but an attempt will be made to recapitulate the more immediate consequences upon existing knowledge. The notion of the invariability of the weights of the simple bodies dominates the whole of chemistry at the present time; it is the scientific basis of all our chemical equations of composition and constitution, the origin of the new and singular algebra which, from its origin in the works of Lavoisier, so struck the mathematicians of his time. It is also the solid foundation of all our analyses, and is a certain starting-point in industries the most diverse, the manufacture of acids, alkalis, colouring matters, scents, drugs, in metallurgy and in agriculture.

And here a necessary reflection occurs. It cannot be pretended that Lavoisier was the direct and personal author of the vast array of discoveries here enumerated; but it is certain that it is he who has established the solid base upon which the modern chemical edifice is constructed, and without which these discoveries could not have been made; it is he who has raised the flaming torch of truth which we daily invoke, and for that reason it is just and equitable to give to him a part of the glory of the inventions of science and modern industry.

---

## NILE FLOODS AND MONSOON RAINS.

THE practice or science of weather forecasting will evidently proceed on two very different lines—according to the relative importance of local or seasonal changes in the general meteorological conditions, and whether the prediction has reference to a long or a short period. The machinery employed in cases where the forecast aims at great minuteness over a small area consists mainly of the synoptical chart, based on information supplied by rapid telegraphic communication, and in the hands of experts this means probably proves sufficient, and furnishes a fair percentage of accurate predictions. But in the more difficult, as certainly the more important, problem of predicting the weather some time in advance, and over a considerable area, a problem which regularly recurs in the monsoon forecast for India, one must evidently depend on the more general physical conditions that are produced by the motions of the earth and the distribution of land and water on its surface. These causes, it is true, are always operative, and to a certain extent meteorological phenomena, broadly considered, must be periodic in their main features. The causes of deviation from periodicity, and the extent of the area affected by such abnormal conditions, are problems which the professional meteorologist has to encounter, and it is to be feared with insufficient means. But it seems not unlikely that, in proportion as the problem becomes more general, by bringing wider areas within the scope of the discussion, the prospects of greater success will become more assured; and it cannot but be considered a most significant feature that indications are not wanting that in the two considerable areas, India and Egypt, the respective climates betray peculiarities which may either react upon each other, or the origin of which must be sought in a common source.

From two independent investigations come attempts to trace a connection between the amount of the Nile floods and the abundance or deficiency of the south-west monsoon rainfall in India. Mr. Willcocks broached this subject in a paper read before the meteorological congress at the World's Exposition in Chicago, and there suggested that famine years in India are generally years of low flood in Egypt, and that when the summer supply of the Nile had been deficient and late, a high flood might well follow, since the drought in the valley of the White Nile must create a powerful draught from the Indian Ocean or the Arabian Sea, a district in which is to be sought the origin of the massive current of the south-west monsoon. Unfortunately, any exact data to establish this interesting connection are not forthcoming, and can hardly be expected, since the Nile is supplied from two distinct sources, and it is impossible to separate and trace the effect of either contribution. Of the great lakes of Central East Africa which constitute a reservoir for the Nile waters, little is known as to the variation in their relative height due to the rainfall in their vicinity, which lasts from March to December. At Port Alice, on the Victoria Nyanza, and at some other stations, observations, more or less regular, are made of the variation in the heights of the water, but in the absence of any common datum level these heights are referred to that of the mean lake. Much surveying work and long-continued observations will have to be made before these scanty statistics can be turned to full account. Of the second source of supply to the Nile, viz. the flood waters in the Atbara, the Blue Nile and other rivers, fed during the rainy season from June to November, we know practically nothing as to their amount. But it is this seasonal supply which is probably the greatest factor in causing variations in the Nile floods, and where a connection with the causes of the Indian rains is closest. Whatever influences the flow of the monsoon current from the equator northwards over the Indian seas towards the heated regions of India and the Malay Peninsula must have a proportional effect on East Africa and South Arabia. With heavy monsoon rains, therefore, it is not unlikely that the contributing rivers add materially to the volume of the Nile waters, but it is not altogether a trustworthy guide to gauge the amount of water that enters the Nile by measuring the quantity that passes a particular station. Much water enters the Nile that never contributes to the irrigation of Egyptian lands. Of the amount lost by evaporation no account can be taken, but a source of greater error arises from the peculiar flatness of the ground about Shambé, which forms the apex of the swamp delta. Here the Nile can spread its waters over a large area, and practically lose itself as a river among the beds of reeds and rushes, which form a veritable swamp. Engineering works, already projected or actually begun, aim at clearing some or other of the feeding streams, such as the Bahr el Gebel or the Bahr el Zarab, and the effect must be, when completed, to break the continuity of such observations as have been made. Other sources of error are to be found in the varying quantity and character of the "sudd" which may interrupt the flow or diminish the amount of evaporation; but without insisting on too much accuracy, there exists a certain amount of evidence that the two great agricultural countries of Egypt and India are likely to be prosperous together or to suffer in common.

Mr. Eliot, the meteorological reporter to the Government of India, in his recent forecast of the probable character of the south-west monsoon rains of 1900, not only fully endorses Mr. Willcocks' statement, but adds some statistics which render a connection highly probable. Omitting a few local particulars from Mr. Eliot's statistical summary, the broad features are shown below.

| Year. | Variation of mean rainfall of year from normal. | Character of Nile flood. |
|---|---|---|
| | Inches | |
| 1876 | – 4·49 | Good high flood. |
| 1877 | – 4·28 | Poor flood. |
| 1891 | – 3·54 | Late flood. |
| 1896 | – 4·83 | Low Nile. |
| 1899 | – 11·14 | Very low flood: lowest of century. |

The years of excess of Indian rainfall tell a similar tale, even more distinctly.

| Year. | Rainfall variation in inches. | Character of Nile flood. |
|---|---|---|
| 1878 | + 6·34 | Very severe flood: banks of river carried away in October. |
| 1886 | + 3·02 | High flood. |
| 1892 | + 5·09 | Very high and late flood. |
| 1893 | + 9·07 | High flood. |
| 1894 | + 6·47 | High flood. |

Having mentioned some of the causes which prevent a rigorous comparison between the Nile floods and the Indian rainfall, one is not unprepared to find some discrepancies; but Mr. Eliot certainly does not overstate his case when he contends that these tables indicate that in at least four out of five seasons in which there was a partial failure of the rains in India there was a low Nile, and that generally the two countries are similarly affected by the meteorological conditions and the variations of those conditions. The causes of these variations are obscure, and at present very imperfectly recognised, for a complete solution, as Mr. Eliot points out, demands a much more intimate knowledge of the atmospheric conditions that prevail over a large area. The meteorology of Australia and the Indian Ocean, and perhaps also of the Antarctic Ocean, must be linked on to that of the Indian monsoon area "before it will be possible to ascertain the missing factors necessary to complete the explanations of the relations between the chief features of the monsoon currents and rainfall of India and the antecedent and concurrent conditions in the Indian area and the regions to the south." To trace and anticipate the effect of weather conditions over the area that embraces both India and Egypt, in which our interests are so largely involved, should stimulate further inquiry, with the result of placing at the command of science additional means for dealing with so grave a problem.

## *THE FORTHCOMING MEETING OF THE BRITISH ASSOCIATION AT BRADFORD.*

IN the last article on the subject of the forthcoming meeting of the British Association an account was given of the handbook that is to be published in connection with the visit, and some information was furnished in regard to hotel and lodging accommodation. In the present article it is proposed to give a description of the excursions arranged by the local committee.

Following the custom of former years, it has been arranged that half-day excursions only shall take place on the Saturday, and that the whole-day excursions shall be reserved until the Thursday, when the serious work of the Association will be completed. The only exceptions to this are that the Mayor and Corporation are inviting a small party of engineers to visit their waterworks at Gowthwaite, in the Nidd Valley, and that a party exclusively for geologists will travel to Pateley Bridge by the same train in order to visit the Brimham Rocks. These two excursions will occupy the whole of Saturday. The excursions, then, arranged for Saturday, September 8, are as follows:—

BOLTON PRIORY.—The party will leave the Bradford (Midland) Station at 1.32. Drive from Bolton to the Priory, where they will be received by the vicar, the Rev. A. P. Howes, who will give a brief description of its history and architecture. They will then drive forward along the banks of the Wharfe to the Wooden Bridge, where tea will be provided: an opportunity will be given for a visit to be made to the Strid (celebrated by Wordsworth), and then the party will be driven back to the station in order to reach Bradford in time for dinner. Mr. Geoffry Fison will be the leader of the excursion.

FARNLEY HALL.—The residence of the Fawkes family, which contains a wonderful collection of Turner's pictures. The Hall is of great historical interest, as it was the residence of Lord Fairfax in the time of the Civil War, and many relics of the period are shown. The party will leave the Midland Station at 1.15 for Otley, where they will be met by Major Mitchell, of Cayley Hall, the leader; they will then be driven to Farnley, and as much time as possible will be spent in inspecting the Turner pictures and the beautiful old Hall. Major Mitchell will afterwards entertain the party to tea in his grounds, and they will then be driven back to the station.

ILKLEY.—The excursion will start from the Midland Station at 1.32, under the leadership of Mr. Mortimer Wheeler; at Ilkley the party will be divided into several smaller bodies, who will in turn visit the Roman camp and fortifications, some curious Saxon crosses that are to be seen in the churchyard, and some remarkable instances of cup and ring marks, which are to be seen on Rombald's Moor above the village. At 4.30 the different parties will reassemble in the beautiful grounds of the Wells House Hydro, where they will be entertained to tea by the invitation of the directors. They will arrive back in Bradford about 7 o'clock.

HAWORTH.—The train will leave the Midland Station at 1.20, and the party will be met at Haworth by Mr. F. Greenwood, the president of the Brontë Society, who will escort them to the church and the Brontë Museum, and show them many places which will be familiar, from description, to the readers of "Shirley." The leader of the party will be Mr. J. A. Clapham.

KNARESBOROUGH.—Major H. D. Sichel will conduct a party to Knaresborough, the train leaving at 1.15. On arrival, the visitors will be divided into two parties, and, under the leadership of Major Sichel and Mr. Arthur Harris respectively, they will be taken by opposite routes to visit the Castle, the petrifying Dropping Well, and Eugene Aram's Cave. Afterwards they will be driven to Plumpton Rocks, where tea will be provided, and they will return by a train reaching Bradford about 7.30.

KIRKSTALL ABBEY AND ADEL.—The train will leave the Midland Station at 1.25, and Kirkstall Abbey will be described by Mr. E. Kitson Clarke, the leader. The visitors will then be driven to Adel Church, which is almost a unique instance of Saxon architecture, and which will be described by the vicar. They will then drive back to the Yorkshire College, Leeds, where they will be entertained to tea by the principal, Dr. Bodington, one of the vice-presidents of the Association.

PATELEY BRIDGE.—As indicated above, this is the only excursion extending over the whole day. Two parties will leave by a special train at 1.15, the one conducted by the Mayor (Mr. Wm. C. Lupton, J.P.), for a small party of engineers, who will be driven from Pateley to the Nidd Valley Waterworks; the other, exclusively for geologists, who, under the leadership of Mr. J. Lower Carter, will walk to the Brimham Rocks, and visit other places of geological interest.

For the week-end (September 8–10), the Yorkshire Naturalists' Union are organising a specially interesting excursion. The district which has been selected is the neighbourhood of Grassington, in Upper Wharfedale, which is not merely a romantically picturesque region, but a remarkably good district for nearly all branches of natural history and geology. The excursion is intended, as far as possible, to be one strictly for practical working naturalists, and as accommodation is very limited, it will be needful to give preference to such members of the British Association as are likely to investigate in their own particular department. The arrangements will be under the direction of leading Yorkshire naturalists, who hope to introduce their comrades from other parts of the country to a remarkably interesting district. There will be the usual fully descriptive circular prepared, which will be sent to any one who may apply for it to the hon. secs. of the Yorkshire Naturalists' Union, Leeds.

THURSDAY, SEPTEMBER 15.—The whole-day excursions arranged for the concluding day of the meeting are as follows:—

THE ACKTON COLLIERY.—This excursion, which will be under the leadership of Mr. C. J. Cutcliffe-Hyne, is intended for a limited number of botanists, geologists and engineers, in order that some opportunity may be given them of examining the Yorkshire coal-measures. The party will be divided into two on arriving at Featherstone: the one will be taken down the pit, while the other will examine the machinery and various interesting material on the bank. They will then meet at one o'clock and will be entertained to lunch by Lord Masham, the owner of the mine, after which the proceedings will be reversed, and the respective parties will be taken round the bank and down the pit; they will then reunite, and after partaking of afternoon tea will return to Bradford.

BOLTON PRIORY.—This is an amplification of the previous half-day visit, again under the leadership of Mr. Geoffry Fison. Fuller opportunities will be furnished of seeing the Priory and the Strid, and lunch will be provided at the Wooden Bridge. In the afternoon a visit will be made to Barden Tower, the ancient keep of the Lord Clifford, of the Wars of the Roses fame, and of his son, the Shepherd Lord.

RIPON AND FOUNTAINS ABBEY.—Mr. Mortimer Wheeler will conduct a party to Ripon; after a special musical service at the Cathedral, they will be driven to Fountains Abbey, and lunch will be provided in the Refectory. They will then be taken over the ruins by the Dean of Ripon, after which the Marquis of Ripon will entertain the party to tea. On returning to Ripon, if time permits, they will be conducted to the crypt and the more interesting parts of the Cathedral by the Dean before leaving for Bradford.

SWINTON PARK.—By the invitation of Lord Masham and under the leadership of the Mayor, Mr. William Lupton, a party will visit Masham. On arrival, they will be driven to Jervaulx Abbey, the ruins of which, of course, possess great historical interest, and will then return to Lord Masham's residence, Swinton Hall, the drive each way being of extraordinary beauty. At the Hall they will be entertained to lunch by Lord Masham, after which the afternoon will be spent in inspecting the very fine collection of Old Masters and modern pictures, and the party will drive to the station to join the special train, which will convey also the party from Ripon.

MALHAM.—A party, under the leadership of Mr. Cecil Slingsby, will leave at an early hour for Bell Busk; thence they will drive across country to Malham, and after lunch they will visit Gordale Scar, and, if time permits, at the invitation of Mr. Walter Morrison, M.P., they will go on to Malham Tarn and Malham Cove. They will leave Malham about 5 p.m. and drive to Skipton, visiting Skipton Castle on the way, and thence by train back to Bradford.

Settle and Clapham.—By the same train which conducts the party to Malham, another party will leave for Settle under the guidance of Mr. J. J. Brigg. After visiting the Victoria Caves, they will drive to Ingleton and lunch. From there they will walk through the beautiful grounds of Mr. J. A. Farrer and explore the Clapham Caves, in which most extraordinary specimens of stalactites and stalagmites are to be seen.

The two last excursions are specially intended for geologists.

York.—It is, of course, essential that York, where the first meeting of the British Association was held seventy years ago, should be visited. The party will arrive in York about 11 o'clock, under the leadership of Mr. J. A. Clapham. The visitors will immediately proceed to see the walls, the museum, and St. Mary's Abbey. Then, after lunch at the Station Hotel, they will visit the Minster, where most of the afternoon will be spent. By the invitation of the Lord Mayor, they will afterwards be entertained to tea at the Guildhall before leaving for the station.

For all the half-day excursions a uniform charge will be made, and similarly for Thursday's excursions there will also be a uniform charge. Visitors applying for excursions will be required to hand in this fee, together with the application form; and tickets, as nearly as possible in accordance with their preferences, will be allotted to them. By making all the excursions of equal cost, it is expected that the work of allotment will be simplified.

The next article will deal with the mayoral and civic functions that have been arranged, and some account will be given of the large garden-party which the municipality will hold on Monday, September 10, and of the various private garden-parties to be given on September 12.

Ramsden Bacchus.

---

## NOTES.

We regret to announce the death of Dr. John Anderson, F.R.S., the distinguished zoologist.

Dr. D. Morris, C.M.G., the Imperial Commissioner of Agriculture for the West Indies, has just arrived in this country.

Prof. G. Carey Foster, F.R.S., has been appointed Principal of University College. Prof. Foster is a Fellow of the College, and was formerly professor of Experimental Physics and Quain Professor of Physics; he is also a Fellow of the University of London, in which University he acted as examiner previous to his election to the Senate.

The International Geological Congress is now in session at Paris. Among the items included in the programme are discussions on international co-operation in geology, fundamental researches for the establishment of a definitive classification, scheme for an international lexicon of petrology, and the photography of types of fossil species.

Reuter reports that Major Gibbons, the African traveller, reached Omdurman on August 20. The line of route traversed by the expedition represents a distance of 13,000 miles. Among the objects attained were the mapping of Barotseland; the accomplishment of the first steam navigation of the Middle Zambesi; and the tracing of the whole course of the river, the discovery of its source, and the determination of its watershed. Thence the route of the expedition was eastward, and by way of the Great Lakes and the Nile.

The annual meeting of the English Arboricultural Society was held at Manchester last week. Prof. Somerville was appointed president for the ensuing year. Reports were read from the judges upon essays on "Foreign *versus* Native Timber," "Agricultural and Woodland Drainage," and "Thinning." The silver medal for the first essay was awarded to Mr. George Cadell, late of the Indian Forest Department, and bronze medals for the other essays were given to Mr. D. A. Glen, of Kirby, near Liverpool, and Mr. A. Dean, of Egham.

The third annual report of the Council of the Röntgen Society shows that the society is making satisfactory progress. The demonstrations at the meetings are very valuable to all workers with Röntgen rays, and the papers and abstracts published in the *Archives* enable members who are unable to attend the meetings to keep well in touch with the latest developments of radiographic work. Dr. J. B. Macintyre, one of the earliest and most prominent investigators with Röntgen rays, has consented to be nominated as the next president of the society.

Sir William Stokes, the eminent surgeon, died suddenly at Pietermaritzburg on Saturday. He filled the post of President of the Royal College of Surgeons of Ireland in 1896; and among his other appointments was the professorship of surgery in the Royal College of Surgeons in 1872, senior surgeon of the Government Hospital of Ireland in 1868, president of the Pathological Society of Ireland, and Surgeon in Ordinary to the Queen in Ireland from 1892. He was the author of a number of addresses, and contributions to the medical press, on clinical and operative surgery.

A Reuter telegram from St. Petersburg states that news has been received there from Dr. Sven Hedin, showing that his expedition this spring to Lob Nor to settle the various questions in dispute regarding that lake and its surroundings has resulted in discoveries exceeding his expectations. He found, in fact, that the lake known to previous explorers no longer exists, having dried up, leaving its bottom strewn with shells and marine growths. Around this old basin, however, a regular system of new lakes has been formed, which Dr. Sven Hedin has explored and mapped. In connection with this announcement, it is worth remark that at the time of the visit of Prince Henry of Orleans to Lob Nor, towards the end of 1889, the lake consisted of a number of interlacing lakes and river-arms, the contraction of the former large water-area being probably due to the using up of the waters of the Tarim for irrigation by the increasing population of the river basin.

The *Scientific American* announces that the U.S. Congress has granted funds for the inauguration of agricultural experiment stations in the islands of Hawaii and Porto Rico. Prof. S. A. Knapp has been selected to investigate the agricultural conditions and possibilities of Porto Rico. He went to the island in June, and will study the lines of experimental investigation which should be undertaken there, places suitable for stations, and the approximate expense of inaugurating and maintaining the work. Dr. W. C. Stubbs will make a preliminary survey of the conditions in the Hawaiian Islands. He sailed for Hawaii about the middle of July, and will spend the month of August in the islands. The conditions there are somewhat different from those of Porto Rico, as a station for experiments in sugar production has been maintained by private beneficence for a number of years.

The Berlin Academy of Science has (says *Science*) made the following grants for scientific work: Prof. Adolf Schmidt, of Gotha, for the collating and publication of material on terrestrial magnetism, 750 marks; Dr. Leonhard Schultze, of Jena, for investigations on the heart of invertebrates, 2000 marks; Prof. Emil Ballowitz, of Greifswald, for investigations on the structure of the organs of smell of vertebrates, 800 marks; Dr. Theodore Boveri, of Würzburg, for experiments in cytology, 500 marks;

Prof. Maxime Braun, of Königsberg, for studies on the Trematodea, 970 marks; Dr. Paul Kuckuck, of Heligoland, for investigations on the development of Phæosporeæ, 400 marks; Dr. Wilhelm Solomon, of Heidelberg, for his geological and mineralogical investigations in the Adamello mountains, 1000 marks; Prof. Alexander Tornquist, of Strassburg, for the publication of his work on the mountains of Vicenza, 1100 marks; Prof. Alfred Voltzkow, of Strassburg, for the drawings of his work on the development of the crocodile, 1000 marks: Prof. Johannes Walther, of Jena, for the publication of his work on deserts, 1000 marks.

WE learn from the *Daily Graphic* that the Norwegian Government has built and fitted out a steam vessel for the express purpose of marine scientific research, and has placed her, as well as a trained staff of assistants, in charge of Dr. J. Hjort as leader of the Norwegian Fishery and Marine Investigations. The vessel herself, the *Michael Sars*, has been constructed in Norway on the lines of an English steam trawler—that type of boat being regarded as the most seaworthy and suitable for such an expedition—but considerably larger, being 132 feet in length, 23 feet beam, and fitted with triple expansion engines of 300 horse-power. The fishing gear includes, *inter alia*, trawls, nets, and lines of all kinds, with massive steel hawsers and powerful steam winches to work the heavy apparatus, while the numerous scientific instruments are of the very best and latest description. The expedition left Christiania in the middle of July, on what may be termed its trial trip along the Norwegian coast (accompanied for part of the time by Dr. Nansen, who was desirous of testing various instruments in which he had made improvements), and has just sailed from Tromsö on a lengthy cruise to the North Atlantic and Arctic Oceans. Dr. Hjort has already added so much to the knowledge of pelagic fishes, their life, habits, and the causes affecting their migrations, that, with the means now at his disposal, a considerable amount of valuable information will probably be gained which will prove of service to the fishing industry of all nations.

MESSRS. JOCHELSON AND BOGORAS, of the Jesup North Pacific Expedition of the American Museum, recently started for the north-eastern part of Asia, by way of San Francisco and Vladivostok, to continue the work of the expedition in Siberia. A few particulars of the investigations undertaken are given in the *American Museum Journal*. The region to be visited is situated north-east of the Amur River. The explorers will study the relations of the native tribes of that area to the inhabitants of the extreme north-western part of America, and also to the Asiatic races visited by Dr. Laufer, under the auspices of the Museum, and to those living farther west. It is expected that in this manner they will succeed in clearing up much of the racial history of these peoples, and it is hoped that the question as to the relations between the aborigines of America and Asia will be definitely settled. Thus the work proposed is part of the general plan of the Jesup North Pacific Expedition, which was organised for the investigation of the relations between the tribes of Asia and America. It is fortunate that this inquiry has been taken up at the present time, since the gold discoveries along the coast of Bering Sea are rapidly changing the conditions of native life; so that within a few years their primitive customs, and perhaps the tribes themselves, will be extinct. It is expected that the journey, which will extend over a period of two years, will result in a series of most interesting additions to the collections of the Museum, and in an important advancement of our knowledge of the peoples of the world.

IT has already been noted (vol. 61, p. 451) that Prof. A. Heilprin has brought forward evidence which throws doubt upon the permanence of the waters of Lake Nicaragua, the fountain head of the San Juan River. His conclusions have been criticised, but he gives further reasons for them in the *Bulletin* of the Geographical Society of Philadelphia (July), and shows that this new factor will have to be taken into consideration in connection with the proposed Nicaragua Canal. The full conclusions now drawn by Prof. Heilprin from data furnished by the Nicaragua Canal Commission of 1897–99, and the special reports of the chief engineer and hydrographer appended thereto, are:—(1) Lake Nicaragua has undergone marked shrinkage during the period of the last twenty-five to fifty years. (2) The shrinkage is a progressive one, and there are no known conditions by which the loss incurred can be made good. (3) The assumption is well founded that the earlier measurements of the altitude of the lake surface, made by Galisteo and Baily, indicating an abasement of the waters by 20 to 30 feet, were accurate. The relations of these conditions to canal construction become immediately apparent, and it may well be agreed that a region subject to the changes which have been indicated "would offer serious obstacles to the construction of a canal of the magnitude of the one proposed or to its permanency after construction."

MR. W. N. SHAW, F.R.S., informs us that Mr. W. Kennedy, the observer for the Meteorological Office at Roche's Point, co. Cork, notes that at 9.15 p.m. (G.M.T.) on August 13 a very large meteor shot into view eastward, going E.S.E. At about an altitude of 70° it exploded with a brilliant flash, and a noise was heard like that of a rocket fired off at some distance. The meteor left a long luminous track visible for some seconds after the explosion. The trail would have been very brilliant but that the eastern sky was lit up by the moon at the same time.

IN the afternoon of Friday, August 17, some parts of the south of London were visited by one of the sharpest thunderstorms that have occurred for some time. The weather was very close, the thermometer reaching 82°, and the distribution of barometric pressure was of a complex character. During the storm, which lasted about an hour, and was accompanied by a heavy hail squall, the amount of rainfall at the central part, near Herne Hill, was 1·2 inch. In some parts of the suburbs the roads were completely flooded, while in others comparatively little rain fell. At Westminster there was none, at Brixton 0·4 inch, and at Greenwich only five-hundredths of an inch. During the same afternoon a severe thunderstorm also occurred at Ilford, Essex.

A DISCUSSION of the thunderstorm observations recorded in 1897 at ten selected stations in India, by Mr. W. L. Dallas, is contained in Part ix. vol. vi. of the *Indian Meteorological Memoirs*. The results for the year have been divided into five-day periods. The storm-frequency varies considerably in different parts, but, generally speaking, the number of storms is unimportant during February and the early part of March; but after the middle of March the thunderstorm season commences, and continues until the middle of October, the maxima occurring towards the end of May and September. After October 23 no storms are reported. Storms are much more frequent in the afternoon than in the morning, and when a storm occurs in the forenoon it is followed, almost without exception, by another in the afternoon. There is a belief that the damage done by lightning in the tropics is slight compared with that done in temperate zones, and the fact that at ten observatories in the year in question only four instances of damage being recorded gives support to this belief.

PROF. CANCANI remarks in a recent paper (*Ital. Soc. Sismol. Boll.*, vi. pp. 37–42) that seismology stands almost alone among the sciences of observation and experiment in that so far no pattern instrument and no comparable apparatus have been introduced. He admits that the Seismological Committee of the British Association have taken a step in the right direction, but considers that the instrument used by them possesses several defects which prevent its general adoption. The conditions which should be satisfied by the type apparatus, he describes as follows: It must be astatic or possess a stationary mass, and must be equally capable of recording the very small and rapid preliminary vibrations and the subsequent undulations of long period; it must have the sanction of experience, the cost of erection and maintenance must be small, and the construction so simple that it does not easily get out of order; it must allow the continuous inspection of the traces, and its sensibility must lie within convenient limits.

ABOUT two years ago Dr. Sambon brought forward evidence that sunstroke was an infectious disease, and consequently due to microbic influences. This view has not met with general acceptance, and Mr. E. H. Freeland, who has had exceptional opportunity of observing cases of sunstroke, both ashore and afloat, shows in the *Middlesex Hospital Journal* (July) that all the phenomena of this affection can be explained on general physiological principles without reference to germs at all. He concludes his paper as follows:—"Whether sunstroke be due to external physical causes, or whether it be an infectious disease and due primarily to a micro-organism which has yet to be isolated, must be decided in the future. For the present it seems to me that there is ample evidence for believing that sunstroke is due primarily to thermic influences—the exposure of the body to a hot moisture-laden atmosphere—and secondarily to the circulation in the blood of certain toxic poisons, the result of perverted tissue metabolism; and that, until more tangible evidence is brought forward to prove that the affection is due to microbic influence, one may safely accept the older doctrine with regard to its causation as a sound working hypothesis, if nothing else."

PROF. F. E. NIPHER, of Washington University, St. Louis, Missouri, has sent some further particulars with reference to the methods he uses to obtain a "zero" plate. His observations upon photographic reversal have already been noticed in these columns (pp. 62, 159), and he has pointed out the bearing of his work upon eclipse photography (p. 246). The following details of the operations he follows may enable other photographers to repeat his experiments. "The plate is placed under a punched stencil in a printing frame. It is exposed at $l$ cm. from a 16 c.p. lamp. By a few trials one can find the time-interval of exposure, so conditioned that nothing will develop on the plate in a developer of fixed composition, strength and temperature, and at a fixed distance from the 16 c.p. lamp. This is a standard developer. With a shorter time of exposure than that giving the zero plate, a negative will result, and with a longer time, a positive. A plate to be used in taking any picture to be developed in the standard developer (as a positive) is all exposed to the 16 c.p. light at a distance $l$ cm. for a time which experiment has shown will put the film into the zero condition when developed in the standard bath. It is then put into the plate-holder, and given a camera exposure in the usual way, after which it is developed. It is not important that the developing bath should be at any particular distance from the lamp. The plate is to be pre-exposed so that a zero plate will result in that particular bath, at any fixed distance from the lamp. I usually make this distance about eight inches."

ACCORDING to Maxwell's electromagnetic theories, a moving body charged electrically produces a magnetic field. In the *Bulletin* of the French Physical Society, M. V. Crémieu gives a brief note on certain experiments destined to test the actual existence of such a field, as well as the converse result that a moving charge placed in a variable magnetic field experiences a certain ponderomotive force. Having, at the suggestion of M. Lippmann, conducted some experiments for the purpose of investigating the latter effect, with negative results, M. Crémieu now gives an account of certain investigations made with a disc of 37 cm. in diameter, rotating at the rate of 100 to 130 revolutions per second in the centre of an annular coil connected with a highly sensitive galvanometer. If the disc is suddenly charged, the convection current thus produced should give rise to an induced current through the galvanometer, and the magnitude of the convection current being determined by the number of revolutions and the density of the charge, the amount of the expected deflection of the galvanometer could be calculated. No deviation of the predicted magnitude was obtained, and the author concluded that a moving charge does not produce a magnetic field. Such a conclusion leads logically to the rejection of existing theories of the electric current, and M. Crémieu proposes to conduct further experiments with the object of throwing more light on this difficult question. The author does not, in this note, say anything about the effects of the self-induction of the rotating disc, and further information on this point appears desirable in criticising the results.

A FEW interesting details referring to the use of wireless telegraphy in the French navy are given by a naval correspondent of the *Daily Graphic*. It is stated that half-a-dozen ships in the combined French squadron recently at Cherbourg were fitted for wireless telegraphy, and the clicking, crackling, and sparking of the big coils was heard on board all day. Messages have been taken in and sent out at distances quite twice or three times as great as anything achieved with the instruments in use in the British ships. The French do not fit the wire to a gaff as in our ships; it is suspended between the funnels to the triatic stay, and is much less conspicuous. The manœuvring of the submarine boats, *Morse* and *Narval*, is described as marvellous; they are, it is stated, much ahead of the American *Holland* boat, which is considered to be a formidable weapon.

AN interesting and detailed account of Count von Zeppelin's successful trial trip of his navigable balloon on July 2 is given in *Die Umschau* by an anonymous author, who has endeavoured to dispel the somewhat exaggerated reports which have been circulated as to the success or failure of the experiment. It is pointed out that the delay in the ascent, which some persons attributed to an accident, was really caused by the wind being too strong at the time originally proposed for the trip. The wind-velocity at the time of starting was 5·5 metres per second, and the balloon was actually driven forwards for a short distance in the face of this wind. But after a short time the path deviated till it made an angle of 30° with the wind-direction. This deviation, the writer explains, was due to several causes. In the first place the rope broke which supported the movable mass necessary for the maintenance of longitudinal balance, and to restore equilibrium it was necessary to stop or even reverse one of the machines, so that the balloon could no longer be driven full ahead. Moreover, the framework was found to have undergone a little deformation, which gave the machine a slight bias to one side, interfering with the steering. The wind causing the balloon to drift towards the shore, a descent was made in order that Count Zeppelin might land on the water (to use an Irishism), and thus have his machine towed back by steamer. The descent was very gradual, the cars gently sinking down to the water without the sudden jerk which is commonly experienced in an ordinary balloon. This result is attributed to the favourable form of the balloon, a cylinder experiencing greater resistance than a sphere. The performance of the motors and screws is described as brilliant.

WE have already referred to the great loss anthropology has sustained in the death of Mr. Frank Hamilton Cushing on April 10. In the current number of the *American Anthropologist* are memorial notices by various leading American anthropologists, from which it is evident that a peculiarly gifted and winning personality has passed away. Mr. Cushing had great manual dexterity and an acute appreciation of how things were made, and he had practised himself to do anything an American Indian could accomplish, and with the same limited resources. For five years he lived with the Zuñi Indians, living their life and familiarising himself with their ideas and modes of thought, and he rose high in the social Pueblo life, taking part in their councils and in their sacred ceremonies. An intense eagerness to learn more and more of aboriginal thought and deed was the mainspring of his life, and his kindly sympathetic nature and keen intelligence and dexterity placed him in the front rank of field investigators. We understand that Mr. Cushing left an immense amount of MS. material, which it is to be hoped will be fully published, for his published works by no means do justice to the extent and value of his researches.

OUR contemporary *Science*, for July 27, contains a summary of the "Lacey Act," recently passed by Congress for the protection of game and other birds in the United States, and for the regulation of the importation of foreign birds and mammals. The carrying out of this important Act has been confided by the Secretary of the Department of Agriculture to the Division of Biology, Dr. T. S. Palmer being the officer selected to supervise its actual administration. Dr. Palmer has lost no time in making known the principles of the new law, having already published a *Bulletin* of the Department, entitled "Protection and Importation of Birds, under Act of Congress, approved May 25, 1900." As regards the importation of wild animals and birds, an absolute veto is placed on certain injurious species; and importers must in all cases obtain special permits from the Secretary of Agriculture before a single individual can be landed. These permits should be applied for in advance. No permits are issued for shipping birds from one State to another, although in certain States the Commissioners of Fish and Game have authority to allow the shipment of a limited number for breeding purposes. No permits are necessary for domesticated birds, and the same applies to natural history specimens for museums. In the case of the larger ruminants special permits will be issued, as heretofore, in the form prescribed for domesticated mammals. The prohibited species include the European house-sparrow, the starling, fruit-bats or flying foxes, and the mongoose, or ichneumon. Special inspectors are appointed to carry out the law, and to give advice in cases of difficulty. The attention of all concerned is drawn to those sections which make it unlawful to ship from one State to another animals or birds taken in contravention of local laws, and which require all packages containing live birds and animals to be clearly marked with the name and address of the shipper, and with the nature of their contents.

WHETHER or no the inferior animals have souls, forms the subject of an article by Herr S. von Uexküll in the *Biol. Centralblatt* of August 1.

IN Part 3 of vol. xxviii. of the *Morphologisches Jahrbuch*, Dr. B. Haller publishes his third memoir on the vertebrate brain, treating specially of that of the mouse, but adding some observations in regard to Echidna. The second article in the same number is by Dr. Fürbringer, and treats of the systematic position of the Myxinoids. The author is of opinion that vertebrates should be subdivided as follows:—

I. Acrania (Amphioxina).
II. Craniota:
    (1) Distoma (Myxinoides).
    (2) Cyclostoma (Petromyzontes).
    (3) Gnathostoma:
        (*a*) Anamia (Pisces, Dipneusta, Amphibia).
        (*b*) Amniota (Reptilia et Aves, Mammalia).

WE have received the *Report* of the Manchester Museum for 1899-1900. From this we learn that the Museum has been enriched during the period in question with two collections of first-class importance, one of these being Mr. C. H. Schill's cabinet of Lepidoptera, and the other the Layard collection of weapons and implements.

IN the concluding part of his "Ornithological Notes," published in the July issue of the *Victorian Naturalist*, Mr. Robert Hall, of Melbourne, discusses the question whether a tree-building diamond-bird (Pardalotes) is the foster-parent of a cuckoo. In the case referred to the young cuckoo was actually seen to be fed by the diamond-bird, one of whose own young was brought up with it. The incident is at present quite unique.

THE Library of the Patent Office is an institution known and appreciated by many students of science, both pure and applied. A series of classified catalogues of the contents of the Library has just been started by the publication of a "Subject List of Works on Photography and the Allied Arts and Sciences." Each volume of the series will contain (1) a general alphabet of subject headings, with descriptive entries, in chronological order, of the works arranged under these headings; (2) a key or a summary of these headings shown in class order. The present list comprises 557 works (73 serials, 484 text-books, &c.) wholly or in part photographic—representing 1300 volumes. The catalogue is really a valuable little bibliography of photography as well as a guide to the contents of the Library.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*), a —— Monkey (*Cercopithecus*, sp. inc.) from West Africa, presented by Mr. L. J. Sparrow; a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, presented by Mr. C. Mackay; three Pheasants (*Phasianus colchicus*), British; a Common Peafowl (*Pavo cristatus*, ♂) from India, presented by Captain G. H. Arnot; a Long-legged Buzzard (*Buteo ferox*), a Black Kite (*Milvus migrans*), two Lesser Kestrels (*Tinnunculus cenchris*), European, two American Kestrels (*Tinnunculus sparverius*) from America, presented by Mr. J. Simonds; a Bengal Weaver Bird (*Ploceus bengalensis*), a Manyar Weaver Bird (*Ploceus manyar*), four Black-throated Weaver Bird (*Ploceus atrigula*), an Indian Roller (*Coracias indica*) from India, presented by Mr. E. W. Harper; a Spiny-tailed Iguana (*Ctenosaura acanthura*) from Central America, presented by Mr. C. Hagenbeck; a Common Lizard (*Lacerta vivipara*), British, presented by Mr. Stanley S. Flower; a Military Macaw (*Ara militaris*) from South America, a Roseate Cockatoo (*Cacatua roseicapilla*), six Blue Lizards (*Gerrhonotus coeruleus*) from Australia, three Blue-tongued Lizards (*Tiliqua scincoides*) from Western North America, a White-collared Kingfisher (*Halcyon chloris*) from India, a Saddle-backed Tortoise (*Testudo ephippium*), three Albemarle Tortoises (*Testudo vicina*), two Thin-shelled Tortoises (*Testudo microphyes*) from the Galapagos Islands, deposited; an Argali Sheep (*Ovis ammon*, ♀) from the Altai Mountains, two Black Storks (*Ciconia nigra*), European; a Ring-necked Pheasant (*Phasianus torquatus*) from China, purchased; four Indian Crows (*Corvus splendens*), a

Little Cormorant (*Phalacrocorax javanicus*), a Green-winged Dove (*Chalcophaps indica*) from India, received in exchange; a Japanese Deer (*Cervus sika*), five Rosy-billed Ducks (*Metopiana peposaca*), bred in the Gardens.

## OUR ASTRONOMICAL COLUMN

VELOCITIES OF METEORS.—At the second annual meeting of the Astronomical and Astrophysical Society of America, recently held at Columbia University, New York, Dr. W. L. Elkin described the apparatus and results of photographs obtained at the Yale Observatory for the determination of the velocity of meteors (*Science*, vol. xii. pp. 125–6). The idea of using photography for this purpose appears to have been first suggested by J. H. Lane in 1860, but it was not until 1885 that Zenker made the next practical attempt in Berlin, and attention has again been recently called to the matter by Prof. Fitzgerald. The Yale apparatus consists of a bicycle wheel fitted with twelve radial opaque screens, fixed so that, while rotating, the screens are brought intermittently in front of the cameras. The wheel as at present worked makes about 50–60 revolutions per minute, but it would be better to increase this speed in future apparatus. A check on the velocity is afforded by records made each revolution on a chronograph. The length of interruption of the meteor trail and the consequent velocity are then determinable if a second observation of the meteor from a distant station has been obtained. In November and December 1899, five such duplicate trails were secured. The apparent velocities of these are given as 50·4, 12·2, 50·3, 20·2, 36·5 kilometres per sec.; their altitudes varying from 45 to 100 kilometres. Correcting the apparent velocities for the attraction of the earth and the diurnal rotation by Schiaparelli's formulæ, the true velocities with respect to the sun are 34·4, 32·0, 32·4, 39·8, 34·0 kilometres per sec.

Comparing these velocities with those calculated on assumption of parabolic or elliptic orbits, the real velocities are in all cases smaller, indicating that the atmospheric retardation has amounted to 8–15 kilometres per sec. The elements deduced for one meteor, an Andromedid, agree remarkably closely with those of Biela's comet, showing the method to be capable of considerable accuracy.

STANDARDS FOR FAINT STELLAR MAGNITUDES.—Prof. E. C. Pickering announced at the above-mentioned conference that a grant of 500 dollars had been made from the Romford Fund for the purpose of carrying out an investigation on the brightness of faint stars by the co-operation of several observatories possessing large telescopes. The point immediately desirable is the accurate measurement of a few stars which shall serve as standards for future work on a larger scale. Five photometers have been constructed, each having a photographic wedge which may be interposed between the eye and the star as seen by the telescope. Thirty-six regions have been carefully selected in different parts of the sky, and twenty stars (five of each of magnitudes 12, 15, 16, 17) are to be chosen in each region, the faintest to be selected and measured with the Lick and Yerkes telescopes. The stars of the 16th magnitude will be measured with the 26-inch of the University of Virginia, and perhaps also with the 23-inch Princeton refractor; those of the 15th magnitude will be measured by the 15-inch Harvard telescope. All of these are to be then compared with stars of the 12th magnitude, whose *absolute* magnitudes will finally be determined with the 12-inch Harvard meridian photometer. After the work is properly got in hand, it is hoped that it may be reduced to a simple routine without sacrificing the quality of the results.

THE TOTAL SOLAR ECLIPSE, MAY 28, 1900.—As more detailed reports of the results obtained by the American observers during the recent total eclipse come to hand, it is interesting to note the increased use which has been made of large diffraction gratings, both concave and plane. In *Science* (vol. xii. pp. 174–184), Mr. L. E. Jewell describes the work at Pinehurst, N.C., and Griffin, Georgia, of the two parties organised by the physical department of the Johns Hopkins University. At each station there were installed two spectroscopes, one having a plane diffraction grating, surface 3 × 5 inches, 15,000 lines to the inch, used in conjunction with a quartz lens to photograph the spectrum of the first order; the other having a concave grating of 10 feet radius and 15,000 lines to the inch, mounted in the usual Rowland form, with a large quartz lens to throw an image of the sun on the slit-plate from a heliostat. The photographs were very successful, and show the spectrum from wave-lengths 3000 to 6000, even the exposures of only one second giving good negatives.

In the same number of *Science* Profs. E. B. Frost and E. E. Barnard describe the apparatus they successfully used during the same eclipse at Wadesboro, N.C.

REPORT OF THE CAPE OBSERVATORY.—In his report for the year 1899 Sir David Gill, Her Majesty's Astronomer at the Cape of Good Hope Observatory, makes special mention of the completion of the new record room, providing storage for manuscripts, the safe preservation and orderly arrangement of the precious astrographic plates, and also serving as the place where the measurements of these plates are undertaken.

The pier and foundations for the new transit circle are completed, but the delay in obtaining the sheet steel dome has kept the work at a standstill. The observations with the transit instrument have been mainly those of the standard stars for the reduction of the Catalogue Astrographic plates. When the new transit circle arrives it will be entirely devoted to the systematic meridian observations of the sun, Mercury, Venus and fundamental stars. With the heliometer, observations of all the oppositions of major planets have been continued.

The 24-inch object glass of the McClean equatorial was returned to Sir Howard Grubb for refiguring, and this instrument has hitherto only been used with a slit spectroscope for stellar spectra. Since the photographic objective was dismounted the 18-inch visual lens has been used for measurements of twenty-one close double stars. The 7-inch equatorial has been used in the revision of the Cape Photographic Durchmusterung, in the observation of suspected variable stars, and in the detection of double stars.

The 6-inch instrument with a Zollner photometer has been used for determining the visual magnitudes of stars in selected areas of different galactic latitudes, the photographic magnitudes of which are already determined. A comparison between the visual and photographic magnitudes will subsequently be made. With the astrographic equatorial 152 *chart* plates and 184 *revision catalogue* plates have been passed. 103 plates, containing 38,785 stars, have been measured during the year, all observations showing an error of 0″·6 being repeated.

Seventy-eight photographs of *Iris* were taken during the period July 11–December 31, with *six* exposures on each plate. In conjunction with meridian observations of comparison stars, it is intended to use the results of the measurements of these plates for determining the mass of the moon.

The geodetic survey of South Africa and Rhodesia has been considerably advanced, but was interrupted by the outbreak of the Transvaal war. The Anglo-German boundary survey has been hindered by the waterless character of the Kalihari Desert, but the work is now completed as far as Arahoab, from which an offset chain will be carried to the 20th meridian.

ROUSDON OBSERVATORY (DEVON).—Sir C. E. Peek sends a pamphlet of sixteen pages containing the sixth contribution of systematic observations of variable stars made at his observatory at Rousdon, Lyme Regis, Devonshire. The present report furnishes the details of the variability of T Cassiopeiæ for the ten years 1889–1898, and of R Cassiopeiæ for the twelve years 1887–1898. The light curves of both stars are also plotted at the end of the pamphlet.

INDEPENDENT DAY NUMBERS FOR 1902.—A small pamphlet has been issued from the Cape Observatory giving the independent day numbers for correcting the places of stars given in the *Nautical Almanac* for 1902. The values of the constants of precession, aberration and nutation employed in these tables are those recommended by the Paris International Conference of 1896.

## THE AUGUST PERSEIDS OF 1900.

OBSERVATIONS of this well-known annual display were much hindered by moonlight, though the weather was generally clear at about the time of the maximum. Our satellite was full on the evening of August 10, and obscured all the smaller meteors. Apart, however, from this interference, the shower of 1900 seems to have been a somewhat scanty one. It furnished a considerable number of large meteors it is true, and of these it is hoped the real paths may be computed; but on the nights of August 10 and 11 observers were somewhat disappointed with the character of their results. The effect of the full moon's influence in practically obliterating a meteoric shower may not, however, have been given sufficient weight. The best night appears to have been August 12, when shooting stars were tolerably frequent considering the circumstances.

But if moonlight presented an obstacle to success in the second week of August, there was no such impediment early in the month and during the last fortnight of July. The earlier stages of the shower were therefore well observed. In fact, it is questionable whether the Perseids have ever been more successfully observed in the month of July. Among those who participated in the observations were Prof. A. S. Herschel, Messrs. J. R. Bridger, W. E. Besley, A. King, and many others. At Cambridge a large number of meteors were recorded. The results show that the first Perseids were noticed on about July 16, and gradually increased in numbers until the date of maximum. The radiant showed the usual E.N.E. motion in a most decided manner.

At Bristol, between July 15–30, in 17¼ hours of observation, 177 meteors were seen, including about 24 Aquarids (radiant $338^\circ - 10^\circ$) and 20 Perseids. But the only night on which a sufficient number of Perseids were registered to indicate a good radiant was July 30, when the position was at $31^\circ + 54^\circ$ from 10 paths. Several of the most prominent of the minor showers of the epoch were observed, and their radiants accurately determined as follows:—

| | |
|---|---|
| $24^\circ + 43^\circ$, 7 meteors | $305^\circ - 12^\circ$, 8 meteors |
| $291^\circ + 59^\circ$, 6 ,, | $315^\circ + 47^\circ$, 9 ,, |
| $292^\circ + 52^\circ$, 7 ,, | $335^\circ + 73^\circ$, 5 ,, |

Other showers were indicated at $53^\circ + 63^\circ$, $245^\circ + 72^\circ$, $333^\circ + 28^\circ$.

Mr. W. E. Besley, at Clapham Common, London, registered the paths of 110 meteors between July 14 and 24, and the great majority of these were seen on the 23rd (30 meteors) and 24th (51 meteors). His results are important, for on the former date he found the radiant point of the Perseids at $23^\circ + 51^\circ$, and on the latter date at $25^\circ + 52\frac{1}{2}^\circ$, from 5 and 7 meteors respectively.

Prof. A. S. Herschel, at Slough, during a series of short watches between July 17 and August 1, recorded 53 meteors, including some very interesting early Perseids and several Aquarids. The position of the latter radiant was placed at $339^\circ - 12^\circ$, from about 7 paths.

Some of the meteors seen by Prof. Herschel were also noted by the writer at Bristol. The earliest Perseid of which duple observations were secured appeared on July 19, at 11h. 49m., and it was a fine object, estimated to equal Jupiter by the Bristol observer. The radiant from the combined paths was at $17^\circ + 50^\circ$, and the height of the meteor varied during its descent from 81 to 54 miles. Another Perseid was seen at Slough and Bristol on July 23, 12h. 12m., of 1st magnitude. Its radiant was at $24^\circ + 52^\circ$, and height 84 to 55 miles. These radiants, together with those determined by Mr. Besley on July 23 and 24, and that by the writer at Bristol on July 30, agree very satisfactorily with the ephemeris place of the radiant given by the writer in *Ast. Nach.*, 3546, and *Memoirs* R.A.S., vol. liii. p. 210.

Fairly bright Aquarids were recorded at Slough and Bristol on July 28 and 30, with heights from 65 to 44 miles and 56 to 40 miles respectively. These meteors are usually lower in the atmosphere than the Perseids, and move much slower. If we take the radiant of the former shower in 1900 as $339^\circ - 11^\circ$, we shall probably have a position which is certainly within 1° of probable error.

On July 15, at 10h. 13m., a Capricornid fireball was seen at Bristol and four other places. It was a splendid object, about three times brighter than Venus, in the northern part of England. It fell from heights of 51 to 21 miles, along a path of 78 miles; velocity, 16 miles per second.

On July 17, at 8h. 47m., a magnificent fireball appeared over the northern part of England and Scotland. Though the sun had not long set, the brilliancy of the meteor was described as very dazzling, and the nucleus left a streak which remained visible for three-quarters of an hour. The meteor was directed from a radiant at $249^\circ - 20^\circ$ in Scorpio, and fell from a height of 58 to 15 miles, along a path of about 175 miles.

On July 24 another fireball appeared, and was rated at about three times the brightness of Venus. It was seen at Bristol and at several stations in the eastern counties. It fell from 68 to 27 miles, along a path of 103 miles; velocity, 19 miles per second, and was directed from a well-known July radiant at $280^\circ - 15^\circ$.

But the number of brilliant meteors which have recently appeared is so large that the objects cannot be alluded to in detail. Many ordinary shooting stars have also been doubly observed, and these will be tabulated and published at a later period. Among these there was an interesting $\theta$ Perseid on July 23, 11h. 13m., with heights of 83 to 59 miles, and a radiant at $30^\circ + 47^\circ$, quite distinct from the true Perseids.

On about August 10–12 the radiant of the Perseids was found far east of its place in July. On August 12, Mr. King, at Leicester, determined the position as $48\frac{1}{2}^\circ + 58^\circ$ from 16 Perseids, and Mr. Besley derived it at $47^\circ + 56\frac{1}{2}^\circ$ on the same night from 4 meteors. On August 16 the writer at Bristol saw 5 Perseids from a radiant at $54^\circ + 58^\circ$.

Though the shower was partially obliterated by moonlight just at the important time, it has this year furnished some interesting materials for discussion as regards its earlier and later stages.

W. F. DENNING.

---

## WHAT PRESSURE IS DANGEROUS ON ELECTRIC RAILWAYS WITH OVERHEAD TROLLEY WIRES.[1]

THE following investigations were set on foot on account of a dissension between the firm of Messrs. Brown, Boveri and Co., Switzerland (Baden), and the authorities regarding the proper pressure for two different electric railways to be worked by three-phase alternating current, namely, the lines Stansstad-Engelberg and Fermatt-Garnergratt, which lines it was proposed to work at a pressure of 750 volts. But this pressure being regarded as dangerous, the authorities refused to allow one exceeding 500 volts to be actually employed.

In these circumstances the firm communicated with Prof. H. F. Weber, of the Zürich Polytechnic, asking him to express his opinion on this matter. In view, however, of his own want of experience on this particular point, Prof. Weber commenced a long series of investigations of the physiological effects of the electric current on the human body, and he used himself as the measuring instrument, thus exposing himself to great danger.

The experiments were made with reference to the special circumstances of the above railways, where the current was supposed to be supplied through two overhead leads, the rails being used as the third conductor of the three-phase system.

Two series of experiments were made corresponding with the cases—

(*a*) A person seizes the two bare leads with both hands simultaneously, or both of the leads fall on a bare part of the human body.

(*b*) A bare part of a person standing on the railway or on a car comes into contact with one of the leads.

The apparatus used in the case of experiments (*a*) consisted of an iron ring wound with 630 turns of wire, through which was sent an alternating current, the frequency of which was 50 per second. The voltage between the first and the last turn was kept at 210 volts. To every thirtieth turn was soldered a copper wire of 10 cm. length, and 6 mm. diameter, and consequently the pressure between the first and the second wire was 10 volts, that between the first and third 20 volts, and so on, up to 210 volts.

Prof. Weber tried these pressures successively on himself, constantly holding with one hand the first wire and seizing with the other hand each of the other wires in succession. The experiments were made three times, his hands being each time wetted to begin with, and afterwards being used dry. The results of each of the three series so obtained were consistent with one another.

When experimenting with *wet hands* he obtained the following results:—

| P.D. | Effect. |
|---|---|
| 10 volts. | Very feeble trembling of the muscles of the fingers; the current from hand to hand was measured and found to be 0·001 ampere. |
| 20 volts. | Very considerable trembling of the hands, wrists and forearms; the hands and the arms were able to be moved freely, and the wires could be |

| | |
|---|---|
| | released easily. The current was from 0·0020 to 0·0027 ampere. |
| 30 volts. | The fingers, hands, wrists, the forearms and upper arms nearly paralysed; the fingers or hand could scarcely be moved; serious pains in the fingers, hands and arms, and the experiment not endurable for more than 10 seconds. The wires could, however, be released, but only by using the greatest determination. Current, 0·015 ampere. |
| 40 volts. | The fingers, hands and arms were instantaneously paralysed, and the pain was almost unbearable. The wires could hardly in any case be released. The pain could not be endured longer than 5 seconds. |
| 50 volts. | Again instantaneous paralysis of all the muscles of the fingers, hands and arms; the wires could not be released; the state endurable for 2 seconds at most, whence it was impossible to measure the current. |

Having obtained the above results, the experimenter did not find it advisable to let the pressure exceed the 50 volts; the fact that when the hands were wet, it was impossible on 50 volts pressure to release the wires, seemed to prove to him that serious danger was just beginning at this point.

With *dry hands* he formed the following results:—

| P.D. | Effect. |
|---|---|
| 40 volts. | The fingers only tingle slightly; the current too feeble for measurement. |
| | The effects gradually increasing and extending to the arms up to the shoulders, until at |
| 80 volts. | The fingers, hands and arms were almost cramped and aching in every part; great effort was required to release the wires; current from 0·009 to 0·011 ampere. |
| 90 volts. | At the same moment in which the wire is seized, the hands are absolutely paralysed and the wire cannot be released again. The pains in the hands and arms were so violent that they caused the experimenter to call out involuntarily; the effects could not be endured for more than 1–2 seconds.<br>The experimenter now went back to 80 volts, and the difference was so great that the effects of this pressure seemed to be extremely feeble relatively to the effects at 90 volts pressure; this fact prevented him from trying the effects of pressure higher still |

From these experiments Prof. Weber draws the following conclusions:—

"A simultaneous touching of both of the poles of an alternating current circuit is dangerous as soon as the pressure exceeds 100 volts; and since it is impossible to set one's self free, the case must be regarded as fatal whenever immediate help is not at hand."

These results are consistent with several disasters which have happened in practical life.

In 1896, in Horgen (Switzerland), a man, to prevent his falling down from a ladder, seized with both his hands two non-insulated leads with a P.D. of 240 volts between them, and was immediately killed.

In a mine in Silesia a workman seized in the same manner some non-insulated leads and was killed on account of his being unable to release them, the P.D. being 300 volts.

In the Electric Central Station in Olten a workman, desirous of proving to his companions that a pressure of 500 volts was quite safe, seized both of the leads and was killed instantly.

From this it is obvious that the general opinion of a pressure of 500 volts not being dangerous does not hold good, the limit being much lower. In spite of the great number of disasters which have already happened, the danger does not seem to have been generally appreciated, and workmen and erectors are often seen to deal with leads and apparatus of relatively high pressures in the most careless manner. That disasters have not taken place far more often may be due to the fact that in most cases help has been at hand instantly.

Entirely differing from these are the results of the other series of experiments (*b*). In this case the person is supposed to stand at one of the poles itself, namely, the earth, from which he is, however, rather well insulated by means of his shoes; and, as it will be evident from the results, the danger is in this case very small even at high pressures.

The arrangement used for this series of experiments consisted of twenty glow-lamps, each for 100 volts pressure, connected in series and all well insulated, the total alternating pressure between the first and the last lamp being 2000 volts. The free terminal of the first lamp was earthed, and between every two consecutive lamps a 6 mm. copper wire was soldered to the main connecting the lamps. Between the earth and the first, second, third to the twentieth of the 6 mm. wires, the pressure was consequently 100, 200, 300, . . . 2000 volts.

Standing on the ground, Prof. Weber touched the different wires—firstly, merely by a slight touch; secondly, by firmly gripping them in his hand. The experiments were made under two conditions, the experimenter standing firstly on moist gravel soil, and afterwards on clay covered by a thin layer of coal-dust.

Standing *on moist gravel soil*, he obtained the following results:—

| P. D. | Effect when the wire was | |
|---|---|---|
| | Slightly touched. | Firmly gripped. |
| 800 volts. | Feeble stinging of the skin. | No effect. |
| | Gradually increasing until at | |
| 2000 volts. | Violent stinging of the skin. | Intense trembling of the fingers. |

Standing on clay covered with coal-dust, he obtained the following results:—

| P. D. | Effect when the wire was | |
|---|---|---|
| | Slightly touched. | Firmly gripped. |
| 200 volts. | Scarcely sensible stinging of the skin. | No effect whatever. |
| 500 ,,<br>700 ,, | Gradually increasing. | The fingers begin to tingle feebly.<br>Intense trembling of the fingers, hands, arms and ankle-joints. |
| 1000 ,, | Stinging like burning by a flame. | The effects in the fingers, hands, arms and feet not endurable longer than 1 to 2 seconds; difficulty in releasing the wire. |
| 1300 ,, | Same effect. | The fingers, hands, and the arms are entirely paralysed, and the wire cannot be released. |

From the last series of experiments it will be obvious that to touch one of the poles is not dangerous as long as the pressure does not exceed about 1000 volts; the intense stinging which appears at the first slight touching serves as a protection against the danger, for the hand is instinctively drawn back rapidly.

The main result of these experiments is, then, that all pressures between 100 and 1000 volts must be regarded as equally dangerous, and consequently there is no reason for not using the higher pressures between 500 and 1000 volts, especially as they lead to greater economy in the working of the electric railway. Further, there is only a very little chance of the passengers or other persons coming into contact with both of the leads. To this danger the employés only are exposed, and being generally people with some electric training, they are acquainted with the danger and may be supposed to be sufficiently careful.

Finally, it is to be remarked that the authorities after these investigations allowed the use of a working pressure of 750 volts as originally proposed.

## *SEA COAST DESTRUCTION AND LITTORAL DRIFT.*

THE increasing number of seaside resorts that are constantly being established all round the coast of this country, and the necessity of protecting the sea front from the devastation of the waves, has led recently to greater interest being shown in the protection of the shores and cliffs.

The means taken to preserve our coasts are as diverse as many of them are ineffectual; and in many cases are designed without any proper consideration being given to the way in which the waves act, or to the physical conditions which have to be dealt with in the management of the littoral drift; while frequently the amenities of the beaches of seaside resorts, and their use and enjoyment by visitors, are impaired by structures as ugly as they are useless to attain the object in view, and in other cases the construction of costly works is rapidly followed by their destruction by the sea.

It is proposed as shortly as possible in this article to state the conditions that have led to the present state of the cliffs and coast, and the conditions under which the material is drifted along the shore. For the purpose of illustration, the coast-line of the south-west of England between Start Point and the Solent has been selected, as this presents features of unusual interest for the study of coast destruction and the drift and accumulation of beach material. The cliffs between these two points consist of a series of rocks of varying degrees of hardness, showing in many places almost vertical faces to the sea, and ranging in height up to 500 or 600 feet. The destruction of these cliffs leads to the deposit, on the beach at their base, of fragments of rock, or inland gravels derived from their summits, which are converted by wave action into shingle, consisting of pebbles of varying character and size, but generally shaped into the form of flattened ovoids, readily distinguishing them from the angular gravels due to glacial drift, or the rounded pebbles rolled down inland rivers.

Originally, no doubt, these cliffs descended to the bed of the English Channel with the same slopes as characterise their land faces, and were washed by the deep water of the sea without the intervention of the sand beaches which now stretch from them, and which, where they exist, have an almost uniform inclination along all parts of the coast.

The present form of these cliffs is due to the destructive action of the waves, or to landslips and weathering from rain and frost. The wearing away has not been regular. Headlands composed of hard rocks project out boldly to low-water mark and beyond, while the softer rocks which formerly adjoined them have been gradually worn away, leaving indents of various shapes and depths.

Some indication of the original position of the coast, and the distance to which it extended beyond the present line, is afforded by the remains of a raised beach, portions of which, consisting of pebbles which have been subjected to marine action, are to be found at Portland Bill on the east of Lyme Bay, at Hopes Nose, near Torquay, at Brixham and in Start Bay on the west.

These beaches are at a much higher level than the present water-line. The direction of this old beach was located by the late Sir J. Prestwich as running in an unbroken line at ten miles outside the present shore between the thirteen- and twenty-fathom contour. There are also patches of gravel near the nine-fathom contour extending all round the bay at about a mile from the shore.

The coast-line has been broken up into three principal indents between the two headlands, namely, Lyme Bay, Weymouth Bay and Bournemouth Bay; the contour of which again is split up into numerous minor bays and coves, the greater number of which have their own peculiar characteristics and contain their own peculiar accumulations of shingle. Two of these shingle banks, namely, the Chesil Bank in Lyme Bay, and that at Hurstcastle at the entrance to the Solent, are, perhaps, the most remarkable accumulations to be found anywhere round the coast of Great Britain; while at Axmouth is one of the most extensive landslips of which there is any record. The fight between sea and land is continuous and unceasing, with the result that the area of this country is gradually being reduced.

The rivers which discharge into the sea along the south coast are few and insignificant in character, and are utterly incapable of transporting from the land the large amount of stones or sand now found on the coast. In some cases they have been blocked up by the littoral drift. A careful consideration of all the circumstances can therefore only lead to the conclusion that some of the results which have been attained must be due to other and mightier forces than those now in existence. These forces may probably be ascribed to the same agencies that gave to this country the shape which it now assumes, and by which the valleys and rivers were scooped out.

At the close of the last great Ice Age the melting of the vast bed of snow which then covered this country must have led to large torrents of water escaping seaward, which would carry with them the debris from the rocks broken up by frost and ice, in the shape of boulders, gravel and sand; and besides leaving deposits in the valleys and those which are to be found on the summit of the cliffs, would carry the degraded material to the sea and form a talus at the level of the water. This deposit, after the wear and tear caused by the waves during long ages, resulted in the present sand beaches.

It is certain that the enormous mass of sand which now covers the littoral of the sea cannot have been deposited by existing agencies. The degradation of the cliffs that takes place is quite inadequate to account for its existence; more especially as only the harder rocks have afforded the material of which the sand is composed, the softer detritus having been carried away in suspension to the depths of the ocean. The sand of the seashore consists almost entirely of grains of quartz of a nearly uniform size, and even where flints abound in the sea cliffs and in the shingle on the beach, this material is conspicuous by its absence in the sand of the shore.

As pointed out in my letter in NATURE of November 30 last, only about one-third of the flints lying on the beaches along the south coast, not only in the part dealt with but also on those bordering on the chalk cliffs extending from Brighton to the North Foreland, and in the large accumulations at the Chesil Bank and Dungeness, are derived from the chalk, the colour of the majority of the flints being different shades of brown, grey, white and red, the former being most prevalent, whereas flints from the chalk are invariably black with a white exterior coating. If the above assumption as to the deposit of land detritus on the coast be correct, it affords a reasonable explanation of this phenomenon.

Another proof that the large accumulations of shingle along the coast are not due to agencies at present operating, is afforded by the fact that the Chesil Bank and Hurst Bank, where the supply of new material drifting along the coast is limited, have not varied materially in shape or increased in size during the time to which the most ancient records relating to them extend, the fresh supply coming from the cliffs being only sufficient in these cases to make up the wear and tear caused by the waves.

The supply afforded by the degradation of the cliffs is after all limited in quantity, and only about equal to making good the waste due to the constant wave action on the shingle. If from any cause an abnormal accumulation takes place on any particular part of the coast, denudation immediately sets in on the coast beyond. Instances of this are afforded by the extension of the Point at Dungeness and the banking up of the shingle on the west side, which has led to a diminished supply all along the Dymchurch and Hythe coasts. The construction of the Admiralty Pier at Dover has led to the denudation of the coast to the northward along St. Margaret's Bay. The pier at Shoreham Harbour for a time denuded the supply at Hove and Brighton; and it is found universally to be the case that where the drift has been stopped by the debris from the fall of the cliffs acting as a groyne extending out to low water, or where artificial works have arrested the progress of the drift, the coast beyond has suffered from denudation.

There is no continuous drift of shingle throughout the whole length of this coast, but the material is confined to the various bays and the banks where it has been accumulated. It has been stated that the land gravel found along the foot of the chalk cliffs at the east end of the English Channel may have been derived from the waste of the gravel beds of the cliffs of Dorset and Hampshire, and that pebbles found on the Chesil Bank have been derived from the coast of Devon; but an examination of the coast shows that under present conditions, at any rate, this is neither the case nor physically possible. For this to have occurred the shingle must not only have passed the numerous headlands which project into the water, but also the approaches to Southampton and Portsmouth, in which the depth of the channels is from five to ten fathoms.

Nearly every bay and cove along the coast here dealt with has its own peculiar accumulation of shingle, which does not travel beyond the projecting headland, and in many cases there are long intervals along the shore where the rock is bare. Thus the shingle in Slapton Bay is of a different character from that found in any other part of the same coast. It consists almost entirely of round white quartz pebbles, resembling peas in shape, and averaging from an eighth to a quarter of an inch in diameter. This shingle not only covers the beach, but has been thrown up into a bank, the top of which is above the level of high tides, and has drifted across a deep indent in the bay, into which two fresh-water streams discharge, entirely closing this from the sea and forming it into a fresh-water lake about two miles long. The quartz pebbles of the Slapton beach do not drift beyond the eastern horn of the bay, and are not to be found in the next recess. All along the Devonshire coast the numerous bays and coves have beaches on which are accumulated shingle derived from the limestone, slate, greenstone, and other rocks which surmount them, while in others there is an absence of shingle and only sand is found. In the bay lying between the headland of the Exe and that at Otterton Point, the beach at Budleigh Salterton is strewn with quartzite boulders and pebbles derived from a large bed contained in the cliffs bordering this part of the bay. These pebbles are of a pink colour, some having marks on them like blood spots. No stones of a similar character are found in the next bay, the drift being stopped by some rock ledges which project out from Otterton Point and form a natural groyne. The shingle in front of Seaton consists almost entirely of the chert and flint derived from the rocks at Beer Head. Beyond this, for several miles there is no continuous bank of shingle, but accumulations are to be found in the bight of the bays, the pebbles being derived almost entirely from the gravel beds in the cliffs. The shingle on the east side of Bridport Harbour is of a different character from that on the west shore, and resembles in size and shape that at Slapton, but the colour of the pebbles is different, these consisting of flint instead of quartz. This small shingle continues all along the coast, and up to the commencement of the Chesil Bank.

The drift of shingle along the shore only takes place above the line of low water, and within the zone covered by the horizontal range of the tide, and it does not accumulate below the line of mean tide level, except where its progress is stopped by encountering an obstruction, and when the quantity has become so great as to extend out into deep water. When the shingle encounters a river of any magnitude, it extends out in a spit across the entrance to the estuary, causing the tides to be diverted from their direct course, and to flow round the end; or else the channel becomes diverted from its course to the leeward, and made to flow in a course parallel with the coast for some considerable distance. Examples of this are found along the coast here dealt with, in the Spits across the estuaries of the Teign and the Exe, and that across Christchurch Harbour, and in the diversion of the streams at Seaton and Charmouth.

The Chesil Bank, which commences near Abbotsbury and extends in a south-easterly direction to the island of Portland, a distance of $10\frac{3}{4}$ miles, has in its course diverted several small streams, which now flow in a channel running parallel with the bank. The width of this great mound of shingle is about 500 feet, and its height varies from 32 to 53 feet, its top being from 23 to 43 feet above high tides.

Hurst Castle shingle bank extends out from the mainland at the entrance to the Solent for $1\frac{1}{2}$ miles, terminating in a hook-like formation on which stands Hurst Castle, erected in the reign of Henry VIII. The bank slopes down across the Solent for a distance of three miles, leaving only a deep narrow passage between its foot and the Needles, in which is from 4 to 9 fathoms of water. This shingle bank forms on its southern side a steep submarine cliff from 20 to 70 feet in height, the face being very steep and dropping almost suddenly from a dry bank to several fathoms of water. So far as any record exists, this bank has not increased or diminished in size or undergone any material alteration since the castle was built. Eastward of the bank there is no drift of shingle, the foreshore for several miles consisting of a wide belt of alluvial deposit.

Another lesson this stretch of coast appears to teach is, that the theory which has generally received acceptance, that the prevailing direction in which the shingle is drifted along any given coast is always in the same direction as that of the prevailing wind, is not founded on fact. This theory may be said to have been settled on the facts brought forward in a paper read at the Institution of Civil Engineers in 1853 on the Chesil Bank, and the discussion which followed.

A careful examination of the facts mentioned in that article do not appear to warrant any such conclusion, but, on the contrary, tends to disprove it. The local movement of shingle along the south-west coast, and also along the other parts of the seashore, are certainly not uniformly in accord with the direction of the prevailing winds of this country. Approximately, the wind in England blows for two-thirds of the year from the south-west. On the east coast the general direction of the drift is from north to south. On the south-west coast the general direction is from west to east. From Beachy Head to Dover it is north-east; from Dover to the North Foreland, northerly; from the North Foreland to the mouth of the Thames, westerly; and north of the Thames south-westerly. On the west coast, the drift is from south to north, up to the middle of the Irish Channel; and north of this, from south to north; and up the Bristol Channel from west to east. In all these instances the movement is in the same direction as the set of the flood-tide.

Although this is the general direction of the drift, there are numerous instances where, owing to the varying set of the tides, the drift moves in three or four different directions within very short ranges. Taking the example of Lyme Bay and the Chesil Bank, the locality where the prevailing wind theory was established, the facts as given by the author of the paper were: That the prevailing direction of the wind on this part of the coast varied between S.S.W. and S.W.½W., which is practically at right angles to the Chesil Bank. If then the drift is in the direction of the prevailing wind, this should lead to a north-easterly movement. The bulk of the materials of which the bank is composed are stated in the paper to have come from the cliffs to the west of the bank, and therefore must have travelled in a south-easterly direction. At the east end of the bank the shingle derived from the debris of Portland moves in a northerly direction. On the other side of the island of Portland, in Weymouth Bay, the shingle is moved in a south-westerly direction; therefore, within the space of five or six miles, the drift is in three opposite directions, not one of which is in the direction of the prevailing winds, but all of which are in the direction at which the flood-tide strikes the shore. Further, it is correctly stated that the effect of winds from the south-west tends to pull down the bank, which is restored again to its normal condition during calms and north-east winds.

Along all tidal coasts it will be found that the general direction of the drift is the same as that of the flood-tide, and that the beach material in bays is moved in the same direction as that in which the wavelets due to the flowing tide break on the beach. It is not contended that shingle is not drifted by waves due to wind. On the contrary, it is a well-known fact that shingle is frequently drifted, first in one direction and then in the opposite, during the occurrence of gales blowing from different quarters obliquely on the shore, and that the beaches are alternately heaped up with material at one place and denuded at another. This process, however, is only occasional and intermittent, and beyond it there is a regular and continuous drift in one given direction, the main course along the coast being in the same direction as the flood-tide, the building up of shingle banks being most active during calms and off-shore winds.

After a long and careful investigation the writer has satisfied himself that the building up of shingle banks and the regular and continuous drift that takes place along the coast are due to wave action caused by the flow and ebb of the tides. As the great tidal wave moves along the deep water of the channels surrounding the coast, its crest is in advance of the sides, which encounter the friction of the shallower water. The swelling tide therefore meets the shore at an angle oblique to its central course. As the lateral flow of the swelling water comes in contact with the shore it is checked and reflected back, causing a series of small undulations or wavelets, which break at the margin of the water.

Although these waves are small, varying in height, according to the condition of the tide and the slope of the beach, from 6 to 24 inches, they are constant, and never cease during the time that the beach is covered by the tide, the number of them varying from ten to twenty a minute. Allowing a mean of fifteen, this gives a total of 3600 impulses during the period that each tide is acting on the shore. These wavelets are never absent from the shore, except when absorbed by larger waves due to wind. As the wavelets break, the water attains a horizontal movement, and aided by the flood current lifts up and carries forward coarse sand and pebbles in a movement oblique to the coast line, and so gives them a slow but continuous forward movement.

The constant murmur that is heard on a shingle beach on days when there is a total absence of wind, and when the sea is perfectly smooth and calm in the offing, attests the fact that the pebbles on the face of a shingle beach are in constant movement. These tidal wavelets are capable of moving and pushing up the face of a shingle bank pebbles weighing from 1 or 2 ounces up to 5 or 6 lbs. A calculation as to the mechanical power of the water contained in an average sized wavelet shows that the kinetic energy developed amounts to 165 foot lbs., which is capable of lifting 9900 pebbles, each weighing 4 ounces, to a height of 1 foot.

W. H. WHEELER.

## *RECENT STUDIES IN GRAVITATION.*[1]

THE studies in gravitation which I am to describe to you this evening will perhaps fall into better order if I rapidly run over the well beaten track which leads to those studies, the track first laid down by Newton, based on astronomical observations, and only made firmer and broader by every later observation.

I may remind you, then, that the motion of the planets round the sun in ellipses, each marking out the area of its orbit at a constant rate, and each having a year proportional to the square root of the cube of its mean distance from the sun, implies that there is a force on each planet exactly proportional to its mass, directed towards, and inversely as the square of its distance from the sun. The lines of force radiate out from the sun on all sides equally, and always grasp any matter with a force proportional to its mass, whatever planet that matter belongs to.

If we assume that action and reaction are equal and opposite, then each planet acts on the sun with a force proportional to its own mass; and if, further, we suppose that these forces are merely the sum totals of the forces due to every particle of matter in the bodies acting, we are led straight to the law of gravitation, that the force between two masses $M_1$ $M_2$ is always proportional to the product of the masses divided by the square of the distance $r$ between them, or is equal to

$$\frac{G \times M_1 \times M_2}{r^2}$$

and the constant multiplier G is the constant of gravitation.

Since the force is always proportional to the mass acted on, and produces the same change of velocity whatever that mass may be, the change of velocity tells us nothing about the mass in which it takes place, but only about the mass which is pulling. If, however, we compare the accelerations due to different pulling bodies, as for instance that of the sun pulling the earth with that of the earth pulling the moon, or if we compare changes in motion due to the different planets pulling each other, then we can compare their masses and weigh them, one against another and each against the sun. But in this weighing our standard weight is not the pound or kilogramme of terrestrial weighings, but the mass of the sun.

For instance, from the fact that a body at the earth's surface, 4000 miles, on the average, from the mass of the earth, falls with a velocity increasing by 32 ft. / sec.$^2$, while the earth falls towards the sun, 92 million miles away, with a velocity increasing by about $\frac{1}{5}$ inch / sec.$^2$, we can at once show that the mass of the sun is 300,000 times that of the earth. In other words, astronomical observation gives us only the acceleration, the product of G × mass acting, but does not tell us the value of G nor of the mass acting, in terms of our terrestrial standards.

To weigh the sun, the planets, or the earth, in pounds or kilogrammes, or to find G, we must descend from the heavenly bodies to earthly matter and either compare the pull of a weighable mass on some body with the pull of the earth on it, or else choose two weighable masses and find the pull between them.

All this was clearly seen by Newton, and was set forth in his "System of the World" (third edition, p. 41).

He saw that a mountain mass might be used, and weighed against the earth by finding how much it deflected the plumb line at its base. The density of the mountain could be found from specimens of the rocks composing it, and the distance of its parts from the plumb line by a survey. The deflection of the vertical would then give the mass of the earth.

Newton also considered the possibility of measuring the attraction between two weighable masses, and calculated how long it would take a sphere a foot in diameter, of the earth's mean density, to draw another equal sphere, with their surfaces separated by ¼-inch, through that ¼-inch. But he made a very great mistake in his arithmetic, for while his result gave about one month, the actual time would only be about 5½ minutes. Had his value been right, gravitational experiments would have been beyond the power of even Prof. Boys. Some doubt has been thrown on Newton's authorship of this mistake, but I confess that there is something not altogether unpleasing even in the mistake of a Newton. His faulty arithmetic showed that there was one quality which he shared with the rest of mankind.

Not long after Newton's death the mountain experiment was actually tried, and in two ways. The honour of making these first experiments on gravitation belongs to Bouguer, whose splendid work in thus breaking new ground does not appear to me to have received the credit due to it.

One of his plans consisted in measuring the deflection of the plumb line due to Chimborazo, one of the Andes peaks, by finding the distance of a star on the meridian from the zenith, first at a station on the south side of the mountain, where the vertical was deflected, and then at a station to the west, where the mountain attraction was nearly inconsiderable, so that the actual nearly coincided with the geographical vertical. The difference in zenith distances gave the mountain deflection. It is not surprising that, working in snowstorms at one station, and in sandstorms at the other, Bouguer obtained a very incorrect result. But at least he showed the possibility of such work, and since his time many experiments have been carried out on his lines under more favourable conditions. Now, however, I think it is generally recognised that the difficulty of estimating the mass of a mountain from mere surface chips is insurmountable, and it is admitted that the experiment should be turned the other way about and regarded as an attempt to measure the mass of the mountains from the density of the earth known by other experiments.

These other experiments are on the line indicated by Newton in his calculations of the attraction of two spheres. The first was carried out by Cavendish.

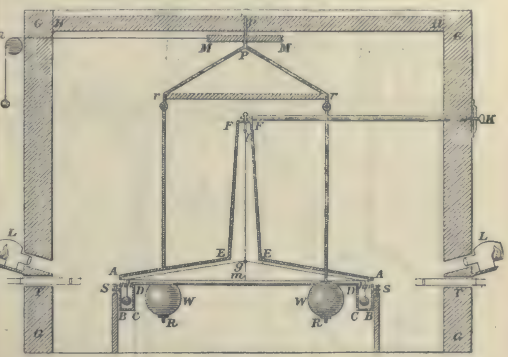

FIG. 1.—Cavendish's apparatus.

In the apparatus (Fig. 1) he used two lead balls, B B, each 2″ in diameter. These were hung at the end of a horizontal rod 6′ long, the torsion rod, and this was hung up by a long wire from its middle point. Two large attracting spheres of lead, W W, each 12″ in diameter, were brought close to the balls on opposite sides so that their attractions on the balls conspired to twist the torsion rod round the same way, and the angle of twist was measured. The force could be reckoned in terms of this angle by setting the rod vibrating to and fro and finding the time of vibration, and the force came out to less than 1/3000 of a grain. Knowing $M_1$ $M_2$ and $r$ the distance between them and the force $G M_1 M_2/r^2$, of course Cavendish's result gives G, or knowing the attraction of a big sphere on a ball, and knowing the attraction of the earth on the same ball, that is, its weight, the experiment gives the mass of the earth in terms of that of the big sphere, and so its mean density. This experiment has often been repeated, but I do not think it is too much to say that no advance was made in exactness till we come to quite recent work.

By far the most remarkable recent study in gravitation is Prof. Boys' beautiful form of the Cavendish experiment, a research which stands out as a model in beauty of design and in exactness of execution (Fig. 2). But as Prof. Boys has described his experiment already in this theatre (*Proc. R.I.*, xiv. Part ii. 1894, p. 353), it is not necessary for me to more than refer to it. It is enough to say that he made the great discovery, obvious perhaps when made, that the sensitiveness of the apparatus is increased by reducing its dimensions. He therefore decreased the scale as far as was consistent with exact measurement of the parts of the apparatus, using a torsion rod, itself a mirror, only 2" long, gold balls, *m m*, only $\frac{1}{4}''$ in diameter, and attracting lead masses, M M, only $4\frac{1}{4}''$ in diameter. The force to be measured was less than $1/5 \times 10^6$ grain.

---

[1] A discourse delivered at the Royal Institution of Great Britain on Friday, February 23, by Prof. John H. Poynting, F.R.S.

The exactness of his work was increased by using as suspending wire one of his quartz threads. It would be difficult to over-estimate the service he has rendered in the measurement of small forces by the discovery of the remarkable properties of these threads.

One of the chief difficulties in the measurement of these small gravitational pulls is the disturbances which are brought about by the air currents, which blow to and fro and up and down inside the apparatus, producing irregular motions in the torsion rod. These, though much reduced, are not reduced in proportion to the diminution of the apparatus.

A very interesting repetition of the Cavendish experiment has lately been concluded by Dr. Braun (*Denkschriften der Math. Wiss. Classe der Kais. Akad. der Wissenschaften Wien*, lxiv. 1896) at Mariaschein, in Bohemia, in which he has sought to get rid of these disturbing air currents by suspending his torsion rod in a receiver which was nearly exhausted, the pressure being reduced to about $\frac{1}{300}$ of an atmosphere. The gales which have been the despair of other workers were thus reduced to such gentle breezes that their effect was hardly noticeable. His apparatus was nearly a mean proportional between that of Cavendish and Boys, his torsion rod being about 9" long, the balls weighing 54 gms.—less than two ounces—and the attracting masses either 5 or 9 kgms. His work bears internal evidence of great care and accuracy, and he obtained almost exactly the same result as Prof. Boys.

Dr. Braun carried on his work far from the usual laboratory facilities, far from workshops, and he had to make much of his apparatus himself. His patience and persistence command our highest admiration.

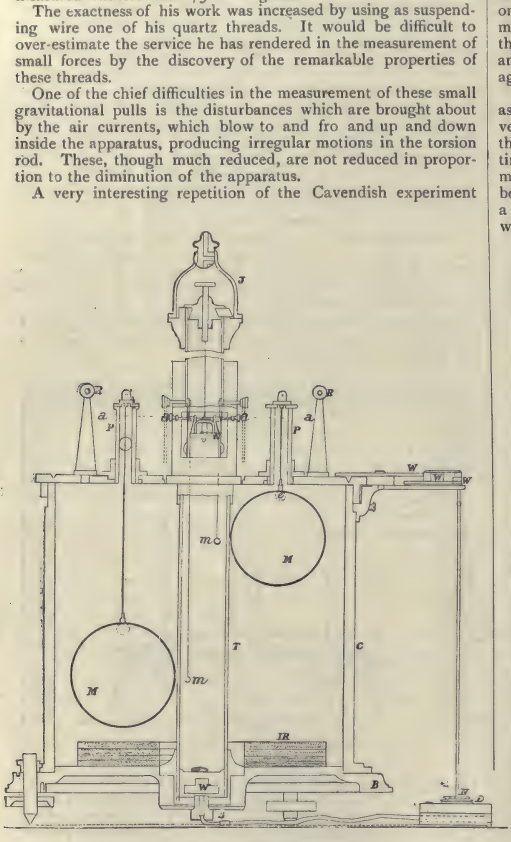

FIG. 2.—Boys' apparatus.

I am glad to say that he is now repeating the experiment, using as suspension a quartz fibre supplied to him by Prof. Boys in place of the somewhat untrustworthy metal wire which he used in the work already published.

Prof. Boys has almost indignantly disclaimed that he was engaged on any such purely local experiment as the determination of the mean density of the earth. He was working for the Universe, seeking the value of G, information which would be as useful on Mars or Jupiter or out in the stellar system as here on the earth. But perhaps we may this evening consent to be more parochial in our ideas, and express the results in terms of the mean density of the earth. In such terms, then, both Boys and Braun find that density 5·527 times the density of water, agreeing therefore to 1 in 5000.

There is another mode of proceeding which may be regarded as the Cavendish experiment turned from a horizontal into a vertical plane, and in which the torsion balance is replaced by the common balance. This method occurred about the same time to the late Prof. V. Jolly and myself. The principle of my own experiment (*Phil. Trans.*, 182, 1891, A, p. 565) will be sufficiently indicated by Fig. 3. A big bullion balance with a 4-foot beam had two lead spheres, A B, each about 50lbs. in weight, hanging from the two ends in place of the usual scale pans. A large lead sphere, M, 1' in diameter and weighing about 350 lbs., was brought first under one hanging weight, then under the other. The pull of the lead sphere acted first on one side alone and then on the other, so that the tilt of the balance beam when the sphere was moved round was due to twice the pull. By means of riders the tilt, and therefore the pull, was measured directly as so much increase in weight. This increase, when the sphere was brought directly under the hanging weight with 1' between the centres, was about $\frac{1}{8}$ mgm. in a total weight of 20 kgm., or about 1 in 100,000,000. If, then, a sphere 1 foot away pulls with $1/10^8$ of the earth's pull, the earth being on the average 20,000,000 feet away, it is easy to see that the earth's mass is calculable in terms of the mass of the sphere, and its density is at once deduced. The direct aim of this experiment, then, is not G, but the mass of the earth.

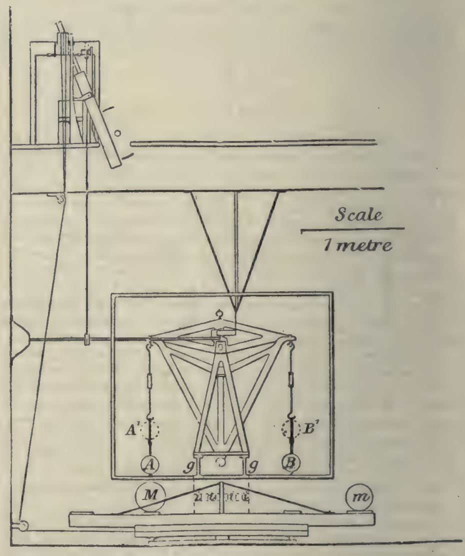

FIG. 3.—Common balance experiment (Poynting).

It is not a little surprising that the balance could be made to indicate such a small increase in weight as 1 in 100 million. But not only did it indicate, it measured the increase, with variations usually well within 1 per cent. of the double attraction, or to 1 in 5000 million of the whole weight, a change in weight which would occur merely if one of the spheres were moved $\frac{1}{40}$ inch nearer the earth's centre. This accuracy is only attained by never lifting the knife edges and planes during an experiment, thus keeping the beam in the same state of strain throughout, and, further, by taking care that none of the mechanism for moving the weights or riders shall be attached in any way to the balance or its case, two conditions which are absolutely essential if we are to get the best results of which the balance is capable.

Quite recently another common balance experiment has been brought to a conclusion by Prof. Richarz and Dr. Krigar-Menzel ("Anhang zu den Abhandlungen der Königl," *Preuss. Akad. der Wissenschaften zu Berlin*, 1898) at Spandau, near Berlin. Their method may be gathered from Fig. 4. A balance of 23 cm., say 9-inch beam, was mounted above a huge lead pile about 2 metres cube, and weighing 100,000 kgm. Two pans were supported from each end of the beam, one pan above, the other pan below the lead cube, the suspending wires of the lower pans going through narrow vertical tubular holes in the lead. Instead of moving the attracting mass, the attracted mass was moved. Masses of 1 kgm. each were put first, say, one in the upper right-hand pan, the other in the lower left-hand pan, when the pull of the lead block made the right hand heavier and the left hand lighter. Then the weights were changed to the lower right hand, and the upper left hand when the pulls of the lead pile were reversed. When we remember that in my experiment a lowering of the hanging sphere by 1½ inches would give an effect as great as the pull I was measuring, it is evident that here the approach to and removal from the earth by over 2 metres would produce very considerable changes in weight, and, indeed, these changes masked the effect of the attraction of the lead. Preliminary experiments had, therefore, to be made before the lead pile was built up, to find the change in weight due to removal from upper to lower pan, and this change had to be allowed for. The quadruple attraction of the lead pile came out at 1·3664 mgm., and the mean density of the earth at 5·505.

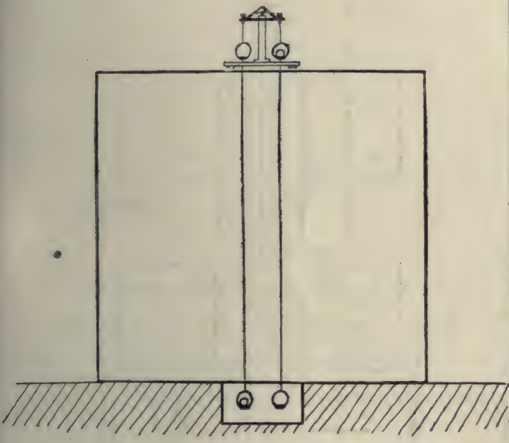

FIG. 4.—Common balance experiment (Richarz and Krigar-Menzel).

This agrees nearly with my own result of 5·49, and it is a curious coincidence that the two most recent balance experiments agree very nearly at, say, 5·5; and the two most recent Cavendish experiments agree at, say, 5·53. But I confess I think it is merely a coincidence. I have no doubt that the torsion experiment is the more exact, though probably an experiment on different lines was worth making. And I am quite content to accept the value of 5·527 as the standard value for the present.

And so the latest research has amply verified Newton's celebrated guess that "the quantity of the whole matter of the earth may be five or six times greater than if it consisted all of water."

I now turn to another line of gravitational research. When we compare gravitation with other known forces (and those which have been most closely studied are electric and magnetic forces) we are at once led to inquire whether the lines of gravitative force are always straight lines radiating from or to the mass round which they centre, or whether, like electric and magnetic lines of force, they have a preference for some media and a distaste for others. We know, for example, that if a magnetic sphere of iron or cobalt or manganese is placed in a previously straight field, its permeability is greater than the air it replaces, and the lines of force crowd into it, as in Fig. 5.

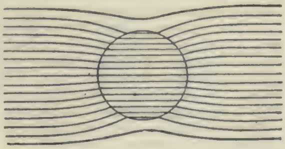

FIG. 5.—Paramagnetic sphere placed in a previously straight field.

The magnetic action is then stronger in the presence of the sphere near the ends of a diameter parallel to the original course of the lines of force, and the lines are deflected. If the sphere be diamagnetic, of water, or copper, or bismuth, the permeability being less than that of air, there is an opposite effect, as in Fig. 6, and the field is weakened at the end of a diameter parallel to the lines of force, and again the lines are deflected. Similarly, a dielectric body placed in an electric field gathers in the lines of force, and makes the field where the lines enter and leave stronger than it was before.

If we enclose a magnet in a hollow box of soft iron placed in a magnetic field, the lines of force are gathered into the iron and largely cleared away from the inside cavity, so that the magnet is screened from external action.

Now common experience might lead us at once to say that there is no very considerable effect of this kind with gravitation. The evidence of ordinary weighings may, perhaps, be rejected, inasmuch as both sides will be equally affected as the balance is commonly used. But a spring balance should show if there is any large effect when used in different positions above different media, or in different enclosures. And the ordinary balance is used in certain experiments in which one weight is suspended beneath the balance case, and surrounded, perhaps, by a metal case, or perhaps by a water bath. Yet no appreciable variation of weight on that account has yet been noted. Nor does the direction of the vertical change rapidly from place to place, as it would with varying permeability of the ground below. But perhaps the agreement of pendulum results, whatever the block on which the pendulum is placed, and whatever the case in which it is contained, gives the best evidence that there is no great gathering in, or opening out of the lines of the earth's force by different media.

Still, a direct experiment on the attraction between two masses with different media interposed was well worthy of trial, and such an experiment has lately been carried out in America by Messrs. Austin and Thwing (*Physical Review*, v. 1897, p. 294). The effect to be looked for will be understood from Fig. 7. If a medium more permeable to gravitation is interposed between two bodies, the lines of force will move into it from each side, and the gravitative pull on a body, near the interposed medium on the side away from the attracting body, will be increased.

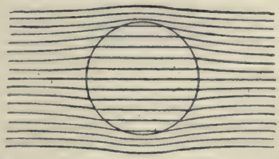

FIG. 6.—Diamagnetic sphere placed in a previously straight field.

The apparatus they used was a modified kind of Boys' apparatus (Fig 8). Two small gold masses in the form of short vertical wires, each ·4 gm. in weight, were arranged at different levels at the ends virtually of a torsion rod 8 mm. long. The attracting masses $M_1$ $M_2$ were lead, each about 1 kgm. These were first in the positions shown by black lines in the figure, and were then moved into the positions shown by dotted lines. The attraction was measured first when merely the air and the case of the instrument intervened, and then when various slabs, each 3 cm. thick, 10 cm. wide and 29 cm. high, were interposed. With screens of lead, zinc, mercury, water, alcohol or glycerine, the change in attraction was at the most about 1 in 500, and this did not exceed the errors of experiment. That is, they found no evidence of a change in pull with change of medium. If such a change exists, it is not of the order of the change of electric pull with change of medium, but something far smaller. Perhaps it still remains just possible that there are variations of gravitation permeability comparable with the variations of magnetic permeability in media such as water and alcohol.

Yet another kind of effect might be suspected. In most crystalline substances the physical properties are different along different directions in a crystal. They expand differently, they conduct heat differently, and they transmit light at different speeds in different directions. We might, then, imagine that the lines of gravitative force spread out from, say, a crystal sphere unequally in different directions. Some years ago, Dr. Mackenzie (*Physical Review*, ii. 1895, p. 321) made an experiment in America in which he sought for direct evidence of such unequal distribution of the lines of force. He used a form of apparatus like that of Prof. Boys (Fig. 2), the attracting masses being calc spar spheres about 2 inches in diameter. The attracted masses in one experiment were small lead spheres about ½ gm. each, and he measured the attraction between the crystals and the lead when the axis of the crystals were set in various positions. But the variation in the attraction was merely of the order of error of experiment. In another experiment the attracted masses were small calc spar crystal cylinders weighing a little more than ½ gm. each. But again there was no evidence of variation in the attraction with variation of axial direction.

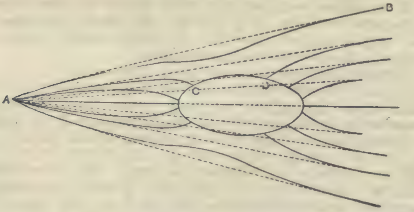

FIG. 7.—Effect of interposition of more permeable medium in radiating field of force.

Practically the same problem was attacked in a different way by Mr. Gray and myself (*Phil. Trans.*, 192, 1899, A, p. 245). We tried to find whether a quartz crystal sphere had any directive action on another quartz crystal sphere close to it, whether they tended to set with their axes parallel or crossed.

It may easily be seen that this is the same problem by considering what must happen if there is any difference in the attraction between two such spheres when their axes are parallel and when they are crossed. Suppose, for example, that the attraction is always greater when their axes are parallel, and this seems a reasonable supposition, inasmuch as in straightforward crystallisation successive parts of the crystal are added to the existing crystal, all with their axes parallel. Begin, then, with two quartz crystal spheres near each other with their axes in the same plane, but perpendicular to each other. Remove one to a very great distance, doing work against their mutual attractions. Then, when it is quite out of range of appreciable action, turn it round till its axis is parallel to that of the fixed crystal. This absorbs no work if done slowly. Then let it return. The force on the return journey at every point is greater than the force on the outgoing journey, and more work will be got out than was put in. When the sphere is in its first position, turn it round till the axes are again at right angles. Then work must be done on turning it through this right angle to supply the difference between the outgoing and incoming works. For if no work were done in the turning, we could go through cycle after cycle, always getting a balance of energy over, and this would, I think, imply either a cooling of the crystals or a diminution in their weight, neither supposition being admissible. We are led, then, to say that if the attraction with parallel axes exceeds that with crossed axes, there must be a directive action resisting the turn from the crossed to the parallel positions. And conversely, a directive action implies axial variation in gravitation.

The straightforward mode of testing the existence of this directive action would consist in hanging up one sphere by a wire or thread, and turning the other round into various positions, and observing whether the hanging sphere tended to twist out of position. But the action, if it exists, is so minute, and the disturbances due to air currents are so great, that it would be extremely difficult to observe its effect directly. It occurred to us that we might call in the aid of the principle of forced oscillations, by turning one sphere round and round at a constant rate, so that the couple would act first in one direction and then in the other, alternately, and so set the hanging sphere vibrating to and fro. The nearer the complete time of vibration of the applied couple to the natural time of vibration of the hanging sphere, the greater would be the vibration set up. This is well illustrated by moving the point of suspension of a pendulum to and fro in gradually decreasing periods, when the swing gets longer and longer, till the period is that of the pendulum, and then decreases again. Or by the experiment of varying the length of a jar resounding to a given fork, when the sound suddenly swells out as the length becomes that which would naturally give the same note as the fork. Now, in looking for the couple between the crystals, there are two possible cases. The most likely is that in which the couple acts in one way while the turning sphere is moving from parallel to crossed, and in the opposite way during the next quarter turn from crossed to parallel. That is, the couple vanishes four times during the revolution, and this we may term a quadrantal couple. But it is just possible that a quartz crystal has two ends like a magnet, and that like poles tend to like directions. Then the couple will vanish only twice in a revolution, and may be termed a semicircular couple. We looked for both, but it is enough now to consider the possibility of the quadrantal couple only.

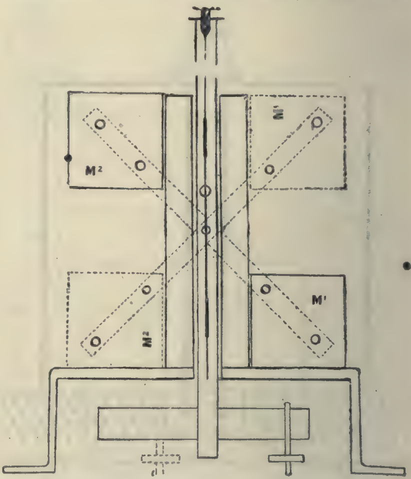

FIG. 8.—Experiment on gravitative permeability (Austin and Thwing).

Our mode of working will be seen from Fig. 9. The hanging sphere, ·9 cm. in diameter and 1 gm. in weight, was placed in a light aluminium wire cage with a mirror on it, and suspended by a long quartz fibre in a brass case with a window in it opposite the mirror, and surrounded by a double-walled tinfoiled wood case. The position of the sphere was read in the usual way by scale and telescope. The time of swing of this little sphere was 120 seconds.

A larger quartz sphere, 6·6 cm. diameter and weighing 400 gms., was fixed at the lower end of an axis which could be turned at any desired rate by a regulated motor. The centres of the spheres were on the same level and 5·9 cm. apart. On the top of the axis was a wheel with 20 equidistant marks on its rim, one passing a fixed point every 11·5 seconds.

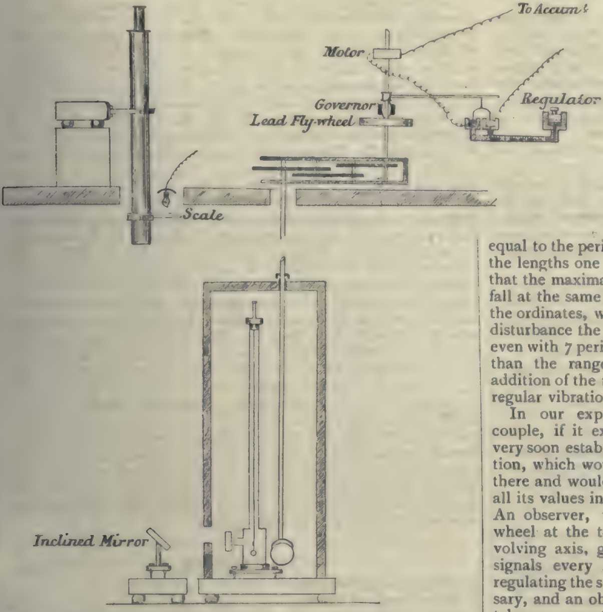

FIG. 9.—Experiment on directive action of one quartz crystal on another.

It might be expected that the couple, if it existed, would have the greatest effect if its period exactly coincided with the 120 second period of the hanging sphere—*i.e.* if the larger sphere revolved in 240 seconds. But in the conditions of the experiment the vibrations of the small sphere were very much damped, and the forced oscillations did not mount up as they would in a freer swing. The disturbances, which were mostly of an impulsive kind, continually set the hanging sphere into large vibration, and these might easily be taken as due to the revolving sphere. In fact, looking for the couple with exactly coincident periods would be something like trying to find if a fork set the air in a resonating jar vibrating when a brass band was playing all round it. It was necessary to make the couple period, then, a little different from the natural 120 second period, and, accordingly, we revolved the large sphere once in 230 seconds, when the supposed quadrantal couple would have a period of 115 seconds.

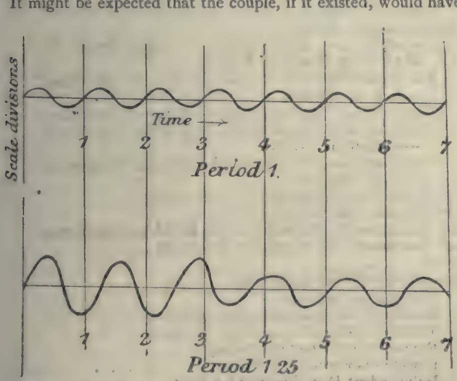

FIG. 10.—Upper curve a regular vibration. Lower curve a disturbance dying away.

Figs. 10 and 11 may help to show how this enabled us to eliminate the disturbances. Let the ordinates of the curves in Fig. 10 represent vibrations set out to a horizontal time scale. The upper curve is a regular vibration of range ± 3, the lower a disturbance beginning with range ± 10. The first has period 1, the second period 1·25. Now cutting the curves into lengths equal to the period of the shorter time of vibration, and arranging the lengths one under the other as in Fig. 11, it will be seen that the maxima and the minima of the regular vibration always fall at the same points, so that, taking 7 periods and adding up the ordinates, we get 7 times the range, viz. ± 21. But in the disturbance the maxima and minima fall at different points, and even with 7 periods only, the range is from + 16 to − 13, or less than the range due to the addition of the much smaller regular vibration.

In our experiment, the couple, if it existed, would very soon establish its vibration, which would always be there and would go through all its values in 115 seconds. An observer, watching the wheel at the top of the revolving axis, gave the time signals every 11·5 seconds, regulating the speed, if necessary, and an observer at the telescope gave the scale reading at every signal, that is, 10 times during the period. The values were arranged in 10 columns, each horizontal line giving the readings of a period. The experiment was carried on for about 2½ hours at a time, covering, say, 80 periods. On adding up the columns, the maxima and minima of the couple effect would always fall in the same two columns, and so the addition would give 80 times the swing, while the maxima and minima of the natural swings due to disturbances would fall in different columns, and so, in the long run, neutralise each other. The results of different days' work might, of course, be added together.

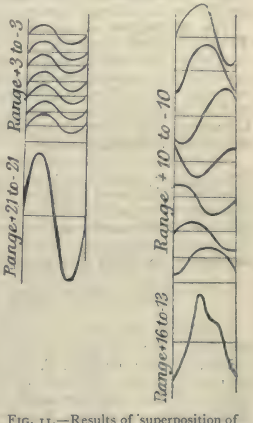

FIG. 11.—Results of superposition of lengths of curves in Fig. 10 equal to the period of the regular one.

There always was a small outstanding effect such as would be produced by a quadrantal couple, but its effect was not always in the same columns, and the net result of about 350 period observations was that there was no 115 second vibration of more than 1 second of arc, while the disturbances were sometimes 50 times as great.

The semicircular couple required the turning sphere to revolve in 115 seconds. Here, want of symmetry in the apparatus would come in with the same effect as the couple sought, and the outstanding result was, accordingly, a little larger.

But in neither case could the experiments be taken as showing a real couple. They only showed that, if it existed, it was incapable of producing an effect greater than that observed.

Perhaps the best way to put the result of our work is this: Imagine the small sphere set with its axis at 45° to that of the other. Then the couple is not greater than one which would take 5¼ hours to turn it through that 45° to the parallel position, and it would oscillate about that position in not less than 12 hours.

The semicircular couple is not greater than one which would turn from crossed to parallel position in 4½ hours, and it would oscillate about that position is not less than 17 hours.

Or, if the gravitation is less in the crossed than in the parallel position, and in constant ratio, the difference is less than 1 in 16,000 in the one case and less than 1 in 2800 in the other.

We may compare with these numbers the difference of rate of travel of yellow light through a quartz crystal along the axis and perpendicular to it. That difference is of quite another order, being about 1 in 170.

As to other possible qualities of gravitation, I shall only mention that quite indecisive experiments have been made to seek for an alteration of mass on chemical combination,[1] and that at present there is no reason to suppose that temperature affects gravitation. Indeed, as to temperature effect, the agreement of weight methods and volume methods of measuring expansion with rise of temperature is good, as far as it goes, in showing that weight is independent of temperature.

So while the experiments to determine G are converging on the same value, the attempts to show that, under certain conditions, it may not be constant, have resulted so far in failure all along the line. No attack on gravitation has succeeded in showing that it is related to anything but the masses of the attracting and the attracted bodies. It appears to have no relation to physical or chemical condition of the acting masses or to the intervening medium.

Perhaps we have been led astray by false analogies in some of our questions. Some of the qualities we have sought and failed to find, qualities which characterise electric and magnetic forces, may be due to the polarity, the + and −, which we ascribe to poles and charges, and which have no counterpart in mass.

But this unlikeness, this independence of gravitation of any quality but mass, bars the way to any explanation of its nature.

The dependence of electric forces on the medium, one of Faraday's grand discoveries for ever associated with the Royal Institution, was the first step which led on to the electromagnetic theory of light now so splendidly illustrated by Hertz's electromagnetic waves. The quantitative laws of electrolysis, again due to Faraday, are leading, I believe, to the identification of electrification and chemical separation, to the identification of electric with chemical energy.

But gravitation still stands alone. The isolation which Faraday sought to break down is still complete. Yet the work I have been describing is not a failure. We at least know something in knowing what qualities gravitation does not possess, and when the time shall come for explanation all these laborious and, at first sight, useless experiments will take their place in the foundation on which that explanation will be built.

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences**, August 13.—M. Maurice Lévy in the chair.—On the neogenic regions of Lower Egypt and the Isthmus of Suez, by MM. C. Depéret and R. Fourtau. Of the Miocene formation the following were recognised:—The Burdigalian, or first Mediterranean stratum, by the presence of *Echinolampas amplus*, *Scutella Innesi*, *Lovenia*, *Cidaris avenionensis*, *Amphiope truncata* and other fossils; the Vindobonian, or second Mediterranean stratum, by a blue lime containing *Pecten cristato-costatus* and numerous echinoderms. Of the Pliocene, in the neighbourhood of Cairo, are layers of yellowish sand containing *Clypeaster aegyptiacus* and other characteristic fossils.—The area of the basins of Russia in Asia, by M. J. de Schokalsky. The map is made upon the scale of 1 in 4,200,000, and the area evaluated by means of a sheet of celluloid divided in square millimetres. The area found is 16,085,000 sq. kilometres.—On a hypsometric map of European Russia, by M. J. de Schokalsky. The previous map of M. de Tillo was limited by the latitude 60° N.; the present map includes the whole of European Russia upon a scale of 1 in 15,300,000.—Observations of the Borelly comet, made at the Observatory of Algiers with the 31·8 cm. equatorial, by M. F. Sy.—A new arrangement of apparatus serving to measure geodesic bases, by M. Alphonse Berget. Ruled plates of iron floating in a bath of mercury are used instead of the ordinary scales. The method has the advantage of securing without trouble the absolute horizontality of the rules; two consecutive rules are necessarily in the same horizontal plane, since their mercury baths are connected; there is no correction necessary for the flexure of the rules, and the temperature correction is much more certain.—Stereoscopic vision of curves traced by a phase apparatus, by M. Marc Dechevrens.—Properties of magnetic deposits obtained in a magnetic field, by M. Ch. Maurain. Iron was deposited in a magnetic field either from a solution of ferrous and ammonium chlorides, or from a solution of ferrous sulphate in sodium pyrophosphate. It was found that the intensity of magnetisation of different layers of the deposit growing in a uniform field has the same value, and that the uniform magnetisation acquired by a deposited strip increases with the strength of field in which the deposit is obtained.—The *rôle* of discontinuities in the propagation of explosive phenomena, by M. Paul Vieille. On the assumption of an adiabatic elasticity, together with continuity, the velocities of wave propagation found in certain cases are too great. It is necessary to assume that the phenomenon is discontinuous.—Action of hydrogen upon the sulphides of arsenic, by M. H. Pélabon. Details of experiments of the interaction of realgar and hydrogen in sealed tubes at 610° C. The reaction is a reversible one, and the limit is affected by the introduction of an excess of arsenic.—The properties of the blue oxide of molybdenum, by M. Marcel Guichard. The blue oxide is a molybdate, and could not be obtained free from water, two oxides of molybdenum only existing in the anhydrous state, $MoO_2$ and $MoO_3$.—On the colouring matter of *Echinus esculentus*, by M. Griffiths.—On the composition of the ashes of some medicinal plants, by M. Griffiths.—On a cause of error in the examination of wines for salicylic acid, by M. J. Ferreira da Silva. The method of Petlet and Grobert will indicate the presence of salicylic acid in a pure wine that is really free from it. The official German method gives exact results.—On a variety of the anthrax bacillus; a short asporogenic form, *Bacillus anthracis brevigemmans*, by M. C. Phisalix. In the organism of the dog the *B. anthracis* undergoes important modifications, becoming shorter with a rapid and complete segmentation. It is still uncertain whether this should be regarded as a variety or a new species.—Antihepatic serum, by M. C. Delezenne.—Application to man of the regeneration of confined air by means of sodium peroxide, by MM. A. Desgrez and V. Balthazard. The apparatus described weighs twelve kilograms, and by its means a man can penetrate easily into an irrespirable atmosphere.

THURSDAY, AUGUST 30, 1900.

## *RIGHT- AND LEFT-HANDEDNESS.*

*Rechts- und Linkshändigkeit.* Von Dr. Fritz Lueddeckens. Pp. vi + 82. (Leipzig: Engelmann, 1900.)

THE chief interest of the treatise under consideration consists in the exposition of a variety of conditions which, in the author's opinion, are associated with that commonly known as right-handedness, a condition which is generally assumed to refer to a greater physical development and functional employment of that side of the body. Moreover, the author seeks to refer all the phenomena upon which his extended conception of right- (or left-) handedness is based to a common cause, which he finds in the existence of a higher degree of blood-pressure in the vessels of one side of the head (and in the common instance, viz. the right-handed one, in the vessels of the left side) than in those of the other. Dr. Lueddeckens is thus firstly concerned to prove the existence of such an inequality in blood-pressure as has just been mentioned, and the earlier pages of his book are devoted to this part of the subject. From an account of the embryological history of the arterial system, and the departures from original bilateral symmetry which that system presents, we are led (p. 8) to a study of the hydrodynamic conditions obtaining in the aortic arch in the living subject, and in this connection it is argued that the circumstances are such as will produce a higher blood-pressure in the left than in the right common carotid artery. The greater frequencies of cerebral hæmorrhage, and of embolism of the arteria centralis retinæ on the left side of the brain, are urged in further support of this view.

If it be conceded that the cerebral hemispheres may differ in respect of the pressure in their arterial systems, it becomes possible to divide individuals into three classes, viz. those in whom the blood-pressure is higher on the left side; those in whom the pressure is higher on the right side; and, finally, there must be a category in which will be ranged such cases as present a degree of blood-pressure which is the same in each hemisphere. The majority of cases will, it is believed, fall within the first of these divisions, and to such cases (ordinary right-handed persons) our attention is first directed: evidence is drawn from a comparison of the structures supplied by the chief branches of the common carotid arteries of each side, and firstly of the structures in the area supplied by the external carotid artery, including various superficial structures and also the ear (internal maxillary artery), and the conclusion is arrived at that there is a predominance in growth and a more easily excitable nervous sensibility (auditory sensations being especially observed) on the *left* side, such preponderance being directly associated with the higher blood-pressure on that side.

In the second place, a number of observations on the shape of the eyeball, and on the comparative dimensions of the two eyes in the same individual, are discussed. For it is argued that a difference in blood-pressure will find expression in a difference in the shape of the eyeball on the same side, and that this difference in shape will, in turn, be manifested by differences between the two eyes, in respect of sight. And it is finally submitted that observations on the respective refractive powers in the two eyes of a number of persons examined with regard to this point bear out the conclusion which was thus arrived at on *a priori* grounds.

Thirdly, differences in the size of the pupil on the two sides are taken as criteria of differences in blood-pressure, the smaller pupil corresponding to the higher blood-pressure, and *vice versâ*. Thus we should, according to the author's argument, expect normally to observe differences in this respect. But inasmuch as such difference between the pupils is, by many authorities, considered to accompany pathological conditions only, the author is at considerable pains to show that a purely physiological difference in size may exist. And so again, his arguments that the difference in blood-pressure will be manifested by a difference in the pupils, and further that the difference is normally (in right-handed persons, that is) indicative of a higher blood-pressure on the left side of the head, are considered to be justified by the number of cases in which the smaller of two "physiologically" unequal pupils was observed in the left eye.

Turning from the special domain of ophthalmic anatomy and physiology, the relative weights of the cerebral hemispheres next claim attention, and Hamarberg's results are quoted as indicative of a slight excess of weight in favour of the left hemisphere. The conformation of the several cortical areas is then described, in allusion to their well-known connection with the voluntary production of movements (and of speech in particular). Sensory phenomena are next considered, and evidence of a right-sided predominance in nervous excitability is adduced from the results of work by Biervliet (on the muscular sense, taste, hearing, sight); and lastly, psychical events are dealt with, though with much brevity owing to the difficulty of obtaining relevant evidence.

Passing briefly over the category of subjects in whom an equal blood-pressure is presumed to obtain on both sides of the head, the remaining class in which the blood-pressure on the right side of the head exceeds that on the left is dealt with much in the same way, and in nearly as much detail, as the first class; and with very similar results, *mutatis mutandis*: in other words, Dr. Lueddeckens finds in the majority of left-handed persons the various sources of evidence which have previously been detailed, and which indicate in the left-handed persons a higher blood-pressure on the right side of the head, just as they indicated this condition on the left side of the head in right-handed persons. Interesting observations on the psychical phenomena of young left-handed individuals are recorded, and in particular their difficulties in learning to write, their tendency to adopt mirror-writing, and the greater frequency of impediments to speech among the left-handed may here be noted. Finally, the tendency of the left-handed to lie on the left side during sleep is commented upon.

The foregoing sketch will, it is thought, render the following comments intelligible. Firstly, the demonstration of an essential and fundamental point, viz. the higher degree of blood-pressure in the area supplied by the left common carotid artery, leaves a good deal in the way of direct evidence to be desired: the most important point urged in support being perhaps the comparatively greater frequency of cerebral hæmorrhage on the left side. The author admits that, as regards the brain, the confluence of the two vertebral arteries (to form the basilar) equalises the conditions on the two sides so far as the parts (medulla, pons, and posterior parts of hemispheres) supplied by these are concerned, whereas the equalising effect is not supposed to be felt in other parts of the circle of Willis. We regret that we can find no direct guidance on this point in Hill's important work on the cerebral circulation.

The arrangement of the great vessels springing from the aortic arch is also a subject that admits of a good deal of discussion in the present connection.

With reference to the auditory nerve (p. 16), and the greater sensibility of the auditory centre in the left hemisphere, it may be mentioned that some support is afforded to this view by the earlier date at which the auditory fibres running up to the first temporal gyrus in the left hemisphere acquire their medulla, and presumably attain a fully functional state (Flechsig). In his observations on the eye, the author is to be congratulated on having devised new applications of routine clinical methods to the elucidation of the questions with which he deals. As regards actual differences in the dimensions of the eyes, it is remarkable that no evidence on this subject is forthcoming from the otherwise exhaustive work by L. Weiss on the anatomy of the eye (*Anatomische Hefte*, Bd. viii. 1897). The recognition of non-pathological differences in the size of the pupils is a point on which it is worth while to insist; moreover, the phenomenon will lose little, if any, of its importance as a physical sign in the early diagnosis of certain nervous diseases (*e.g.* general paralysis of the insane). As regards the weights of the hemispheres of the brain, it may be well to remark that there appears to be a mis-quotation on p. 49, where the weight of a left cerebral hemisphere is stated to be 218 gm., and that of the corresponding right hemisphere 133 gm. only; at any rate, if there is not a mistake in quoting Hamarberg's figures, the brain could hardly be regarded as other than pathological, and consequently valueless in this connection. But more important than this is the fact that Braune's extensive weighings show that the difference between the two hemispheres is quite negligible. At the same time we may mention that, according to Bastian, the specific gravity of the left hemisphere exceeds that of the right. Finally, we do not feel inclined to agree with the author in explaining instances of the existence of double personalities on the supposed presence of equal blood-pressure in right and left common carotid arteries.

On the whole, we think that while the amount of evidence in support of the author's main assumption might well be increased, at the same time the clear record of observations, and the deliberate discussion of their significance, will render Dr. Lueddeckens' volume of much interest to biologists.

W. L. H. DUCKWORTH.

## *MODERN VIEWS ON THE CHARACTERS OF THE CELLULAR ELEMENTS IN THE BLOOD.*

*Histology of the Blood: Normal and Pathological.* By P. Ehrlich and A. Lazarus. Edited and translated by W. Myers, M.A., M.B., B.Sc. Pp. xiii + 216. (Cambridge: At the University Press, 1900.)

NOT much more than a year has elapsed since the first part of "die Anæmie," by Ehrlich and Lazarus, appeared in Nothnagel's "System of Pathology and Therapeutics"; but during that short time the work has taken a foremost place among those dealing with the histology of the blood. Perhaps the most striking feature of the book is its originality, broad lines being laid down along which future investigators may work, and no subject is taken up without being enriched by some suggestive hypothesis based on interesting observations made by Ehrlich himself or some of his pupils. Although comparatively a small book, it may be said, without disparagement to the many other works on hæmatology, to be the one to which the term "epoch-making" may, without exaggeration, be applied. It is only possible to refer shortly to some of the most important subjects discussed in its pages. Although it is undoubtedly with reference to the leucocytes that the most important observations are made, there are also points of great interest treated of in the chapter dealing with the morphology of the erythrocytes. This is especially the case with regard to the authors' views on polychromatophilia as a sign of degeneration, and on the method of transformation of megaloblasts to megalocytes and normoblasts to normocytes. Not less important are the paragraphs dealing with the megaloblastic type of the blood and marrow in pernicious anæmia. But it is when the authors come to discuss the normal and pathological histology of the white blood corpuscles that we find on every page observations that shed light on points that have been long in obscurity.

Although the authors belong to a comparatively small school that believes in the absolutely distinct characters of two types of white blood corpuscles, lymphocytes and granular leucocytes, yet no one, whatever his own opinions may be, can rise from a perusal of these pages without granting that no stronger case could have been presented in support of this view than the one placed before us in this book. Perhaps it is mainly to Ehrlich and Ribbert in Germany, and Muir in this country, that we are indebted for the most powerful arguments against the view that all leucocytes are developed from the lymphocyte. The arguments presented in this book in favour of the view that there are two great types of white cells, are obtained from morphological, experimental, pathological and clinical data. The morphological characters of the different forms of white cells are first described in a very lucid manner. There is an exceedingly valuable contribution to our knowledge of the functions of the spleen in Kurloff's work on the effects of removal of that organ from guinea-pigs. The functions of the lymph glands and bone marrow are described, and additional evidence is given in favour of the two-fold type of the white blood corpuscle.

The chapter dealing with the demonstration of the cell granules and their significance is, of course, one in which Ehrlich, as a pioneer in this subject, naturally finds himself at home. He repudiates Altmann's claims to priority with regard to the importance of cell granules. The description of the different types of leucocytosis and leucocythæmia is exceedingly good, and perhaps constitutes the most valuable section of the work. It is unfortunate that the translator has not seized the opportunity, as he has done in the case of Kanthack and Hardy's investigations, of referring to the very important work done by Muir on experimental leucocytoses and leucocythæmia. It is to him that we are indebted in the first place for the recognition of the "leucoblastic" type of marrow in experimental leucocytosis.

Ehrlich's chemiotactic theories with regard to the emigration of different cells from their seat of formation, the marrow, into the blood, and from the blood into the tissues, &c., are presented in a most interesting fashion, although, unfortunately, it is still impossible to speak about the etiology of medullary leucocythæmia in anything but the most indefinite way. To Dr. Myers' translation one can only refer in terms of praise. Perhaps it errs at places by being rather too literal. References to Jenner's eosin-methylene blue mixture, and to Kanthack and Hardy's work, are welcome additions made by the translator and editor. Confirmation and amplification of the very important investigations of Kanthack and Hardy, and Hardy alone, on the solution of oxyphil granules when cells containing the latter come in contact with chains of *B. anthracis*, &c., would be heartily welcomed by all who are interested in the subject of leucocyte secretions.

T. H. MILROY.

## BIOLOGY AT WOODS' HOLL, U.S.A.

*Biological Lectures from the Marine Laboratory at Woods' Holl, U.S.A., for* 1899. Pp. 282. (Boston: Ginn and Co., 1900.)

THE present volume, like all its predecessors, is replete with interest and full of testimony to the activity and good work of the Whitman School. It contains the reports of sixteen lectures, of which as many as four are for the first time botanical; and although among the zoological writers we miss the names of Whitman and one or two of the most tried among his earlier collaborateurs, the effects of their teaching and example are all evident. More especially is this the case with the lectures by C. M. Child on "The Significance of the Spiral Type of Cleavage," and by E. Thorndike on "Instinct," in which certain of Whitman's most famous conclusions receive support.

Conspicuous lectures are those by C. B. Davenport on "The Aims of the Quantitative Study of Variation," and by Jacques Loeb on "The Nature of the Process of Fertilisation," each in extension of work for which these investigators are now well known. The latter writer, dealing with facts which show that the process of fertilisation and development may be produced in the egg cell by the action of certain salts, to an advanced stage, would have us believe he has transferred the problem of fertilisation from the realm of morphology into the realm of physical chemistry. There is an important address by Alphæus Hyatt on "Some Governing Factors usually neglected in Biological Investigations," in which the uniformitarian hypothesis receives a check and a defence is set up of a law of "Tachygenesis" or "abbreviated development"; and there is incorporated in it a discussion on heredity, in its bearings on Ribot's argument that it is a "specific memory," and that a form of automatism is the link between memory and habit.

T. H. Morgan continues to write on "Regeneration," and among the lectures there are two which are noteworthy as embodying full bibliographies, of service for reference—viz. those by A. G. Mayer on "The Development of Colour in Moths and Butterflies," and by G. N. Calkins on "Nuclear Division in Protozoa." Interest amounting to novelty is greatest as concerns the work of C. H. Eigenmann on the breeding habits of the blindfishes, the Amblyopsidæ, of the Mississippi Valley, in which the discovery that the bleached condition is assumed by the young even when reared in the light, is brought forward as evidence of hereditary establishment of an effect of the environment; and as concerning a lecture by H. S. Jennings on "The Behaviour of Unicellular Organisms," in which, from the fact that a multiplicity of causes may bring about similar reactions, it is argued that organisation and not the nature of the stimulus determines the result of experiment. Of the botanical lectures, that by D. H. Campbell on "The Evolution of the Sporophyte" furnishes an argument in favour of the abandonment of aquatic life having had a potent influence in its higher development, while another by D. P. Penhallow will be useful, as giving a succinct account of the alteration and carbonisation processes undergone by vegetable organisms during fossilisation. The remaining lectures are upon the effects of temperature and currents of air upon distribution, the significance of mycorrhizas, the associative processes in animals, and the "Physiology of Secretion"; and the *tout ensemble* gives promise of increased attention in the future to questions of cytology, in both their experimental and physiological aspects, with a leaning to those which involve philosophic principles and abstract ideas. No doubt much of the biological work of the next generation will be of this type, but in view of the probability that that may stand in danger of being overdone, and of the idea that nothing remains possible on the old lines, it may be said that in the very book under review there is reached the conclusion that "it is the individual which is the unit and not the cell." In the future, when everything will need to be gone over again under an advance in methods and a better understanding, the facts of mere anatomy—the value of which there is a growing tendency to depreciate—will assuredly prove as important and instructive as in the past. Our American brethren may do well to bear this in mind.

## OUR BOOK SHELF.

*Brief Guide to the Commoner Butterflies of the Northern United States and Canada.* Being an Introduction to a Knowledge of their Life-histories. With Illustrations of all the Species. By Samuel Hubbard Scudder. Pp. xi + 210; 22 plates. (New York: Henry Holt and Co., 1899.)

OUR notice of the first edition of this work appeared in NATURE for August 10, 1893. This is not before us while writing; but as far as we can tell without actual comparison, the present edition, as regards the letterpress, is little more than a reprint of the first. But the plates are a welcome addition. They represent seventy-three species, without colour, carefully drawn and easily recognisable, though sometimes badly printed. The small size of the book renders it very convenient for handy reference. A European entomologist will recognise one or two old friends, such as the Camberwell Beauty, the Painted Lady, Red Admiral, and a Small Copper, hardly distinguishable from our own; but the proportions of the various families and genera are very different from what obtains in Europe. A single plate, representing five species, and another representing only six species, are enough to illustrate the Satyridæ, and the Blues and Coppers together; while a much more crowded plate is required for the Hair-Streaks, and two for the Skippers. There are also several very large and conspicuous species, including six large Swallow-Tails, and the northern representatives of several tropical genera. But although the average size of the North American butterflies is much larger than ours, and much of the settled part of the country lies much further south, the number of species in the Northern States is much smaller than in Europe, owing to the comparative absence of Satyridæ and Lycænidæ; and it is not till we reach the frontiers of Mexico that the vast wealth of the tropical American butterfly fauna (almost equalling that of all the other continents put together) begins to dawn upon us.

W. F. K.

*Elements of Qualitative Analysis.* By G. H. Bailey, D.Sc., Ph.D., and G. J. Fowler, M.Sc. Pp. 115. (Manchester: J. E. Cornish, 1900.)

AMONG the distinctive characteristics of this addition to the already numerous volumes on practical chemistry are: the prominence given to the recognition of common elementary substances by an examination of their simple physical and chemical properties, the attention given to dry methods of analysis, and the series of flame-reactions. These sections provide students of practical chemistry with excellent exercises in manipulation, and will counteract the belief that the best way to analyse a substance is always to dissolve it and go through the usual routine treatment of solutions and precipitates. There is little sympathy with ordinary qualitative analysis at the present time, but where the subject is taught it should be taught intelligently; and as this little book provides a reasonable course of laboratory work, it merits a trial.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Railways and Moving Platforms.

ABOUT twenty years ago I was in the habit of speaking with Prof. Ayrton and other friends about a scheme which might increase ten-fold the carrying capacity of the Underground Railway. I prepared a letter for the *Times* newspaper about two years ago, but at the earnest entreaty of a friend I applied for patent protection for the scheme, and did not publish the letter. I have not proceeded with the patent, and wish now that I had published the letter. Indeed, I wish that, instead of merely talking the matter over with friends twenty years ago, I had published what I had to say.

Travelling now on the new Central London Railway, one feels that there is enormous waste of energy and of time in starting and stopping the trains. Again, a train must not be longer than the platform. On my scheme the train does not stop, and the longer it is the better. Indeed, I can imagine an endless train keeping a perfectly constant speed all the time.

My scheme is easy enough to understand now that moving platforms are common. After passengers enter a station I get them gradually into a state of motion, so that moving alongside the train and at the same speed, they may enter and other passengers may leave. There are many ways in which the scheme may be carried out. From a wayside station passengers may enter an express train which does not stop, in the following way. They enter a small train at the station; this train gradually gets up a speed equal to that of the express; it runs alongside the express at a particularly well-laid part of the line; there is an exchange of passengers, and the local train gradually comes to rest again at the station.

For the Underground Railway, the method which most commended itself to Prof. Ayrton and me long ago was this. At a station, say St. James's Park, the platform was a carefully constructed turntable, 500 feet in diameter, the rim of which travelled at 8 miles per hour. The whole area was not really a floor; it was only a skeleton of a turntable, being an outer rim 8 feet broad and many radial passages. The very long train to Mansion House, travelling at 8 miles per hour, was close to the rim of the turntable; indeed geared with it in a rough, simple manner for less than half its circumference; the train from Mansion House did the same on the other side. I need not speak of the automatic opening and closing of the doors of the train.

A passenger, let us say second class for Mansion House, takes his ticket and descends a spiral staircase, which revolves so slowly that even the frailest and most timid of old ladies is not frightened; in fact, it revolves on its own axis once in 134 seconds. At the bottom the passenger sees a few notices; one of them saying second class, Mansion House, has a hand pointing along a radial passage, and this is followed. As the passenger moves radially, he does not notice that he is gradually getting up speed circumferentially. He does not notice that the floor gets slightly inclined as he moves out, to counteract the small effect of centrifugal force. When he reaches the outside of the platform he probably finds a train there, seemingly at rest, with the doors open, and he enters it, moving perhaps along the platform, choosing one compartment rather than another. If he is lucky he has about one minute in which to make his choice. But he will notice near him on the platform an altering time signal which tells him how much more time he has to waste: 50 seconds, 40, or 30, or 20, or 10; if he delays after the signal says 0, an iron railing will come between him and the train; he will see the train moving laterally away from the platform, and he must wait seventy-four seconds before he sees a train coming laterally towards him; the railing goes away, and he has again sixty seconds in which to enter.

If he had a third class ticket to South Kensington, he would have proceeded in exactly the same way. Also every passenger wanting to leave the train at St. James's Park had sixty seconds in which to do it. Trains at 16 miles an hour give only half these times. A platform of only 250 feet diameter would give only half the time if the train speed was 8 miles an hour. I need not dwell upon the details of this and other methods which suggest themselves. It may be soon or syne, but I feel sure—I have felt sure for many years—that my method will have to be adopted.

JOHN PERRY.

August 11.

### Snow-drifts on Ingleborough.

IN his interesting letter on "Snow-drifts on Ingleborough in July," Prof. Hughes describes what may be called the first stage in the formation of a glacière. These ice-caves, not very rare in parts of the Alps and Jura, were made by the present Bishop of Bristol the subject of an attractive book (published thirty-five years ago), and have been occasionally noticed in the earlier volumes of NATURE and elsewhere. I have always believed that snow, drifted into caves during the winter, was the initial cause of these natural ice-houses (about half a dozen of which I have visited), and can quote a case from the Alps which is a slight variation of that described by Prof. Hughes. On July 24, 1873, I went up the Pic d'Arzinol (9845 feet) from Evolena in the Val d'Hérens, and on the way down—so far as I remember between five and six thousand feet above sea-level—my guide diverged from the track to show me what he called the Pertuis Freiss. These were two fissures, apparently joints, opened by a slight subsidence. A description of one will serve for both, except that there was hardly any descent to its floor. The fissure extended some four yards into the hill, and was at widest about as many feet. Ice was patched about the floor, and in places formed a plaster on the walls, its thickness being at most three inches. It showed prismatic structure, though rather small. The air within was cold (I had no thermometer); but as the surface of the ice was wet, it was above 32° F., though I think not much. The guide told me that the fissures in winter-time were filled with snow. This accumulation, probably owing to the shape of the fissure, no longer remained as snow, but was represented by the ice on the floor and walls, which the guide said seldom, if ever, disappeared. The absence of ice from the walls of the Ingleborough "swallow hole" was probably due to some exceptional dryness of the rock; but Prof. Hughes has undoubtedly found a "baby" ice-cave, like that I have described, and it will be worth examining some more of these dry shafts to see whether a slightly better developed specimen may not be lurking in the neighbourhood. T. G. BONNEY.

### Permeability of Iron under the Influence of the Oscillatory Discharge from a Condenser.

IN your issue of August 2 there is an abstract of a very interesting paper, read by Prof. Trowbridge, on his experiments with a battery of 20,000 secondary cells. In it he mentions that the permeability of iron when under the influence of a very powerful discharge from a large condenser is now under observation.

I should like to draw attention to some experiments I was making over a year ago in Lord Blythswood's laboratory (an account of which has not yet been published), in which I have gone into the subject in some detail.

In my experiments the lowest frequency used was about 5000 a second. I enclose two photographs of sparks taken in the usual way with a revolving mirror. The discharge in photograph (1) took place through a coil of about 5 millihenrys self-induction from a battery of Leyden jars of a total capacity of ·06 microfarads, the potential difference between the coatings, before discharge, being 13,500 volts. In photograph (2) a fine wire core, consisting of 550 No. 28 soft iron wires, was inserted into the coil (which was wound on a hollow paper spindle of about 1·3 cm. internal diameter). The other conditions of discharge were identical in the two cases; the speed of the mirror, however, was 19 revolutions per second for photograph (1), and 16 per second for photograph (2), thus tending to draw out the spark more in the first photograph.

FIG. 1.

FIG. 2.

The essential differences are, however, well marked. At the beginning of the discharge we have the "pilot" spark, first noticed by Prof. Boys; and then in the photograph (2), taken with the iron wire cores, a series of oscillations gradually increasing in length. The first half-oscillation, however, is nearly twice as long as the half-oscillations in photograph (1), when there were no iron wire cores in the coil. The increase in the time for a half-oscillation is due, of course, to the increased self-induction of the coil on account of the iron; and the gradually-increasing length is due to the increase in permeability of the iron as the intensity of the discharge dies away. In photograph (1) the frequency of oscillation of the spark taken with the coil having air cores is about 9000 per second, and in (2) the approximate magnitude of the current during the first discharge with the iron cores, 15 amperes.

It would be impossible in the course of a short note to describe in detail the work that has been done, but in numerous experiments (over three hundred spark photographs have been taken) that have been made, the iron has been found to behave in the same way under these oscillating magnetisations as it does when steady currents are used to produce magnetising forces of the same intensity. In most experiments single layer coils have been used in which the magnetising forces due to a given current can be calculated, and it has been possible to determine approximately the forces acting on the iron. From the results, curves showing the variation in permeability with magnetising force have been plotted. In some experiments, the magnetising current due to the discharge has been as large as 1000 amperes. In order to obtain discharges as powerful as this, a very large glass-condenser has been used with a total capacity of 1·5 microfarads, made up of plates of glass (coated with shellac) 1·6 mm. (1/16″) thick. The conducting surfaces are of tinfoil. The glass appears a great deal stronger than that used by Prof. Trowbridge, as it has been tested repeatedly at 20,000 volts. It is possible, however, that the suddenness with which his condenser is charged from his cells may account for the readiness with which the glass breaks. In my experiments the condenser was charged by a large Wimshurst machine of 160 plates, which took almost half a minute to get up the full potential of 20,000 volts. The glass used is known technically as 15 oz. 3rds selected flat sheet, and was obtained from Messrs. Malloch, of Glasgow. E. W. MARCHANT.

Blythswood Laboratory, Renfrew, August 7.

### Function of the Whips of the Larva of the Puss Moth.

YOUR correspondent (p. 389) will find a detailed account of the various defensive appliances of the larva of *Cerura vinula* in Prof. Poulton's work on the "Colours of Animals" (International Science Series), and in papers published by him in the *Transactions* of the Entomological Society of London for 1886 and 1887, the latter papers being illustrated by beautiful coloured plates.

It is usually believed by entomologists that the function of the "whips" in the caudal appendages of the larva is to drive away, or frighten away, Ichneumon Flies or other enemies, but there is still room for further inquiry; and although the larva is highly protected, it is liable to the attacks of some species of Ichneumon Flies, though it may be able to defend itself against others, for the protection of no animal is absolutely complete.

The appendages are doubtless homologous with the retractile fleshy fork in the neck of the larvæ of the Swallow-tailed Butterflies (Papilionidæ), which probably fulfils a similar function. W. F. KIRBY.

Hilden, Sutton Court Road, Chiswick.

### The Migration of Swifts.

ON the morning of Friday, August 10, I witnessed a large flight of Swifts travelling westward along the Sussex coast. The birds were passing this place in a continuous though thin stream for several hours; I saw them myself from 10 a.m. when I first visited the shore, and watched them till 12 noon. A few birds were also noted travelling in the same direction between 5 p.m. and 6 p.m. The day was bright but showery, and a fresh W.N.W. breeze was blowing at the time, so that the birds were flying almost against the wind; they flew low, seldom rising fifteen feet in the air, and often passing within two feet of my head as I lay on the shingle; they kept to the coast-line and for the most part over the top of the fringe of tamarisks that here stretch for miles just above the shingle. Since that day I have not seen a single Swift in the neighbourhood, in spite of having travelled on my bicycle as far west as the mouth of Chichester Harbour along the coast, and to various places north of this line as far as Chichester and Arundel inland. It would be interesting to know if other observers witnessed any similar flights on August 10, and also if Swifts are still to be seen in any places in our islands at the present time. I have on two previous occasions seen Swifts arrive on the east coast of Norfolk as late as the first week in September (after a complete dearth of the birds for some three weeks), and depart again after a few days' sojourn—these perhaps are migrants from the European continent. As many of your readers are now doubtless at the seaside, it seems a favourable opportunity to ask them to keep their eyes open and record any facts that they may observe bearing on the movements of these birds. OSWALD H. LATTER.

East Preston, near Worthing, August 19.

## *UNITS AT THE INTERNATIONAL ELECTRICAL CONGRESS.*

AT the suggestion of Prof. Hospitalier, Section I. of the Congress agreed that the following should be the members of the Commission on Units:—Messrs. Ayrton (Great Britain), De Chatelain (Russia), Dorn (Germany), De Fodor (Hungary), Eric Gérard (Belgium), Hospitalier (France), Lombardi (Italy), Kennelly (United States); and at the first meeting of the Commission, on August 21, which was attended also by Prof. F. Kohlrausch and Sir W. Preece—whose names had been added to the list of the Government delegates for Germany and England—a report presented to the Congress by the American Institute of Electrical Engineers was taken into consideration. This report had been drawn up for that Institute by a committee appointed for this purpose, and it contained the following resolutions:—

(1) We consider that it is necessary to give names to the absolute units in the electromagnetic and electrostatic systems, as well as convenient prefixes to designate the decimal multiples and submultiples of these units in addition to those already in use.

(2) The International Congress of Electricians, which will take place this year in Paris, should be invited to choose the names and the prefixes.

(3) A great advantage would be gained by a rationalisation of the electric and magnetic units, and the Congress should be invited to find ways and means to obtain such a rationalisation.

The proposition to rationalise the units—that is, to change them so that the coefficient $4\pi$ should not appear—was withdrawn by Dr. Kennelly on behalf of the United States; as well as the suggestion regarding the employment of prefixes, and it was resolved that:—

The Commission will only deal with propositions that will introduce no change in the decisions arrived at at previous congresses.

A long discussion then took place as to whether it was really necessary to give names to the C.G.S. units either in the electrostatic or the electromagnetic systems, and finally it was agreed to withdraw the proposition so far as it dealt with the electrostatic system.

The desirability of giving a name to the unit of magnetic field and to the unit magnetic flux was strongly urged, and as the names of *Gauss* and *Weber* had been employed for some years in America for these units respectively, the advantage of adopting these names for the C.G.S. units of field and flux was advocated. On the other hand, the resolution arrived at by the Electrical Standards Committee of the British Association in 1895 to employ these names respectively for other units was pointed out. Finally, the Commission, at the end of their second sitting, on August 22, recommended the following:—

"The Commission is not of opinion that it is necessary to give names to all the electromagnetic units.

"However, in view of the use already of practical instruments which give the strength of a magnetic field directly in C.G.S. units, the Commission recommends that the name *Gauss* be assigned to this unit in the C.G.S. system.

"The Commission proposes to assign to the unit of magnetic flux, of which the magnitude will be subsequently defined, the name of *Maxwell*."

These resolutions were brought before Section I. of the Congress on August 24, and led to a long discussion. M. Mascart opposed the giving a name to the C.G.S. unit of magnetic field. The employment of practical instruments for the direct measurement of the strength of magnetic fields in C.G.S. units was not, in his opinion, a sufficient reason for assigning a name to that unit. Besides, this decision of the Commission appeared to be contrary to the spirit of the Congresses of 1881 and 1889, which did not give the names of men to the C.G.S. units. He admitted that the name of a man might be given to the practical unit. In any case, the name of "Gauss" seemed to him liable to give rise to confusion, for Gauss was the originator of the first absolute system employed, viz. that of the "millimetre-milligramme-second" system, and that system, as distinguished from the "centimetre, gramme, second" system, was still in actual use in certain cases—for the measurement of the earth's field, for example.

Prof. Kohlrausch said that the "absolute units" were enough for the physicists, but that, if the engineers felt the need of practical units, Dr. Dorn and he did not see that any inconvenience would arise from names being given to them, such as those of Gauss and of Maxwell, for example. The German delegates could not, however, commit their Government in the matter, and they considered that the Congress should limit its recommendations to the use of these new names without seeking that legal sanction should be given to them.

Prof. Ayrton agreed with M. Mascart, and mentioned that during the past five years many "Ayrton-Mather Field Testers" had been constructed to read off the strength of a magnetic field directly in C.G.S. units, but that no need for any special name for that unit had been felt in connection therewith. He added, however, that, while holding the opinion expressed by M. Mascart that it was not desirable to give the names of persons to the C.G.S. units, the units of field and flux had this peculiarity, that without any multipliers they were the practical units adopted.

To this M. Mascart replied that the word "practical" in this connection was ambiguous, since, although it was true that the C.G.S. units of magnetic field and flux were employed in practice, they did not belong to the so-called "practical system."

M. Hospitalier appealed to the Section to give names to the unit of field and the unit of flux. He did not ask for any legal decision in the matter, for the names were put forward as a simple recommendation to the Section.

After a discussion in which Messrs. Ayrton, Carpentier, Dorn, Hospitalier, Kohlrausch, Mailloux, Mascart, A. Siemens, Silvanus Thompson and others took part, Prof. Eric Gérard stated that in his opinion it was desirable to come first to a decision that names should be given to the C.G.S. units of magnetic field and to flux of magnetic induction.

M. Mascart, expressing his approbation of this idea, the president of the Section, M. Violle, put the following proposition formally to the meeting:—

"The Section recommends the adoption of specific names for the C.G.S. units of magnetic field and of magnetic flux." This proposition being adopted, with only two dissentients, the meeting was adjourned for a short time to enable the members to exchange their views regarding the exact names that should be employed. On the meeting reassembling, the president put the two following propositions successively:—

(1) *The Section recommends the adoption of the name of* GAUSS *for the C.G.S. unit of magnetic field.*

(2) *The Section recommends the adoption of the name of* MAXWELL *for the C.G.S. unit of magnetic flux,*

both of which were adopted with only two dissentients.

On the same afternoon these resolutions of Section I. were submitted to the Chamber of Government Delegates to the Congress and adopted, and finally, at the closing meeting of the Congress on Saturday, August 25, the action which had been taken in the matter was formally reported by M. Paul Janet, one of the two secretaries of the Congress.

## *THE AMERICAN INSTITUTE AND THE ENGLISH INSTITUTION OF ELECTRICAL ENGINEERS IN PARIS.*

STARTING with a trip in electric launches up the Thames on Sunday, August 19, a lunch at Henley, visits to electric works in London and its neighbourhood on Monday, a dinner in the evening with many Anglo-American patriotic speeches, a trip to Chatham on Tuesday, inspection of the dockyard, a second lunch, more speeches, and a reception by General and Mrs. Fraser in the afternoon, the members of the two electrical societies prepared themselves to encounter a somewhat blowy passage in journeying together to Paris.

On Thursday, August 16, the formal joint meeting was held in the large hall of the American Pavilion at the Exhibition, with Mr. Carl Hering, the president of the American Institute, and Prof. Perry, the president of the English Institution, as joint chairmen. The American, unlike the British Royal Pavilion, is a large circular building stretching uninterruptedly from floor to dome with a series of galleries running round it, and it is fitted up as a kind of huge commercial club, whereas the British Pavilion has been designed to represent an old English manor house, and contains a loan collection of the finest examples of the British school of painting, chiefly of the eighteenth and early nineteenth centuries.

When one remembers the invasion of England with American machinery—especially electric machinery—one envies the commercial instincts that have produced the American Pavilion, with all its facilities for aiding commerce, its lifts, the doors of which magically glide open and shut again on touching a button, and in which you are rapidly and noiselessly wafted to any of the many galleries.

In our Pavilion, on the contrary, commerce has been relegated to a top room, reached by a back staircase, entered literally through a back door, and the lift connected with this commercial room has not advanced—and never will advance—beyond the construction of the well for it. But walk in at the front door, and you can feast your eyes on the work of Gainsborough, Reynolds, Romney, Constable, Turner, Lawrence, Hoppner, Opie, Hogarth and of others; and, after the roar of the Exhibition, the grinding of the moving platform running all round it, and the rumbling of the electric railways, you feel as if you had passed out of the whirl and money making of a factory into the peace and grandeur of Westminster Abbey. Why, however, has the British Royal Commission made so little use of this treasure on the Quai d'Orsay?

Mr. Hering welcomed the members of the two electrical societies present, and expressed the hope that this meeting might be the forerunner of many joint meetings, the next of which he hoped to see held in the United States, and an invitation to attend that meeting he daintily expressed in English, French and German.

Prof. Perry followed, and stated that, although no minutes could be read of any previous joint meeting, minutes of the present meeting were being taken, as he felt sure that there would be another joint meeting at which they would have to be read.

Prof. Mascart rose to express the thanks for the honour which the English Institution had done him in electing him one of their four vice-presidents some months ago. He hoped that not only might there be a joint meeting of the two societies in the United States—at Philadelphia, for example—but that it would be one at which all the Institutions of Electrical Engineering in the world would be represented. And although he feared that advancing age might prevent his being present, he would none the less co-operate in spirit.

The special subject dealt with at the present joint meeting was:—"The Relative Advantages of Alternate and Continuous Current for a General Supply of Electricity, especially with regard to Interference with other Interests," and the discussion was opened by Mr. Ferranti. He stated that this was not a continuation of the old contention between the relative advantages of direct and alternating current, for the rivalry which formerly existed between the two systems, and which led the advocates of the one to regard everything as absolutely wrong which was done by the advocates of the other, was luckily dying out. Engineers had begun to realise that the direct and the alternate current systems of electric distribution had each their separate functions, and the object of the present discussion was to elicit an expression of opinion as to whether the "interference with existing interests" did not furnish an important consideration in the choice of the system to be adopted in a particular case. It was not merely, he urged, the damage to water and gas pipes that was *now* being caused by the employment of the direct current that had to be taken into account, but they had to bear in mind the value of the underground property that might be injured ten years hence if the great development of the distribution of electric energy, which must necessarily take place in that period, were carried out on a wrong plan. He concluded by expressing the opinion that the difference in the magnitude of the disturbance caused by the two kinds of current was very great.

Mr. Arnold next spoke as a member of the American Institute—it being arranged that representatives of the two bodies should speak alternately. He drew attention to the difficulty of using the alternate current for general distribution arising from the inability to satisfactorily balance the load, and he considered, therefore, that the direct current system was the better. And, in view of the difficulties which attended the employment of the alternating current for driving electric tramcars, he considered that in this case also the direct current was the one to be adhered to.

Sir William Preece reminded the meeting that he has not given his adhesion publicly to either the direct or the alternating current system, and, therefore, that he was in a position to speak quite impartially. He considered that the interference of alternating current circuits with telephone lines could be entirely overcome by the employment of a metallic return for the telephone, but it had to be admitted that the surgings which occasionally took place in alternate current circuits disturbed the block signalling on railways. He referred to a case in France where the triphase alternate system of working had supplanted the direct current one, and suggested that this was an indication of the increasing appreciation of the former method, and that the capacity of long cables introduced a serious difficulty with alternate current transmission.

The variety of frequencies employed by the various companies—the London Electric Supply Company, for example, using a frequency of 67, while the City of London Company employed 97—he regarded as objectionable, and he hoped that this joint meeting would deal with the importance of arriving at a uniform standard of frequency. He also suggested that the relative advantages of underground and overhead conductors might well occupy the attention of the meeting.

Dr. Kennelly spoke of the relative fields for direct and alternating currents, and gave as an example that with an isolated plant of moderate size a direct current at a pressure of 100 volts might be employed, while if the area to be dealt with was larger, the current might still be direct, but a pressure of 200 or 240 volts would have to be resorted to, whereas when the area became large, transformation became necessary, and for that the alternating current was, of course, especially well adapted.

He referred to the growing use of high pressure alternating currents for transmitting power to tramways, and performing a double transformation for supplying the low pressure direct current for driving the electromotors on the cars; and he considered that this unnecessary complication arose from the tramway motor having been developed as a direct current motor, and from the difficulty that would now be experienced in replacing the many tens of thousands of direct current tramway motors with an alternating current type. In the case of new tramways and railways, at any rate, he looked forward to the time when the alternating current would alone be employed, but he admitted that the electric simplification would be accompanied with greater risk of shock and danger to life.

As to the interference that might be caused by electric tramways to magnetic observatories, he thought that, in view of the far greater commercial importance of the tramway, the magnetic observatory would have to give way, and remove its apparatus to a place where electric tramways were not required by the public.

Prof. Ayrton expressed the view that, since no doubt existed as to the considerable damage that electrical undertakings had caused to underground pipes, telephones, submarine cables and magnetic observatories, the question arose whether an endeavour was to be made to prevent the attack or to strengthen the defence. In the case of telephone circuits the Joint Committee of the two Houses of Parliament in England had decided that since—wholly apart from the advent of electric tramways—the Telephone Companies had realised that, in order to prevent interference between the telephone lines themselves, as well as to prevent the disturbance caused by neighbouring telegraph lines, it was necessary to abandon the earth-return and employ a metallic return, and since such a metallic return would shield the telephone circuit from disturbance that might otherwise be caused by electric tramways, there was no necessity to debar the tramway from employing the earth.

But as regards the electrolytic destruction of gas and water pipes the matter was quite different, and, therefore, the Board of Trade had imposed a regulation forbidding the difference of potential between any part of the rail and the terminal of the dynamo being allowed to exceed 7 volts. Prof. Ayrton pointed out, however, that this limit was too high even to prevent electrolysis, and certainly would not prevent the mutilation of messages received through a submarine cable which was landed in the neighbourhood of an electric tramway, as instanced at the Cape of Good Hope.

He questioned whether the security anticipated by Mr. Ferranti and others that would follow from a general substitution of alternating for direct current would be nearly as great as was imagined, and he referred to the experiments which he had published some years ago on the comparatively rapid production of separated hydrogen and oxygen that could be obtained in an ordinary sulphuric acid voltameter, through which an ordinary *alternating* current was passing. The specimen of a pipe corroded with an *alternating* current of one ampere passing for six weeks lying on the table, and which had been sent to the meeting by Mr. Trotter, of the Board of Trade, was an important illustration of the electrolytic action that could be produced with the commercial alternating current supplied by the London Electric Supply Company.

A magnetic observatory was in a more serious position still, since, as the undisturbed magnetism of the earth had to be measured, no system of defence could be utilised, and nothing short of the absence of attack could be satisfactory. He was glad, therefore, to say that the Electric Tramway Companies in London, thanks to the action of the Board of Trade in appointing a joint committee to represent the commercial and the tramway interests, and thanks to the experiments and the negotiations carried out by this committee during the past eight months, had not regarded the preservation of magnetic records from the drastic point of view advocated by Dr. Kennelly. In fact, the president of their Institution, Prof. Perry, in co-operation with Prof. Rücker, had succeeded in inducing the London Tramway Companies to propose a scheme in which, first, all the lines within a radius of two miles round the Kew Observatory should be divided up into absolutely *distinct one mile sections*; secondly, that the current should be led to the trolley wire and withdrawn from the rails at the *middle* of each of these sections; and, thirdly, the difference of potentials between the rails and the earth within this two miles radius should never be allowed to exceed one-fifth of a volt. And with these conditions, calculation showed that, although the protection afforded would not, of course, be as good as that obtained with a wholly insulated system, it would be probably sufficiently great to prevent any appreciable interference being caused with the magnetic observations regularly taken at the Kew Observatory.

M. Corda thought the adoption of the alternate or the direct current was mainly a matter of cost, and since the Fire Insurance Companies allowed the maximum pressure to be used with the alternating current to be only half as great as with the direct current, he considered that as long as that regulation lasted the direct current must gain the day.

Prof. Crocker said that the interference produced by an electric circuit on another undertaking might be divided into that produced by induction and that produced by leakage. The disturbance of the apparatus in a magnet observatory was due to both causes, but, as there were so few magnetic observatories in the world, that particular disturbance might be dismissed from consideration. With alternating currents the disturbance produced by induction was the more serious because this induction set up currents in other wires, and it was, therefore, very difficult to avoid. With direct currents the leakage disturbance was the more serious, but it was possible to prevent this. Some time ago he had had occasion to test the insulation of the whole of the New York electric lighting system, which was split up into sections for this purpose, and he found that the current which leaked to earth did not exceed one per cent. of the current that was supplied to the houses, whereas with the gas system in New York from 10 to 20 per cent. of the gas was lost by leakage. Consequently, since very high insulation could be obtained with the type of underground cables that were employed with high pressure work, it followed that the leakage on the low pressure electric light system employed in New York could be reduced to a still lower value than one per cent. Further, that if it were possible in London to reduce the potential difference between the rails and the earth to only half a volt, he should imagine that electrolysis might be avoided even with the ordinary trolley wire tramway. He was, therefore, in favour of employing the direct current for the purpose of avoiding interference with other interests.

But he considered that the considerations of economy and efficiency were more important than those regarding interference, and, while the three-phase and the direct current motors of the same power had the same efficiency from half up to full load, the direct current motor was the more efficient for small loads. Further, while for constant speed the regulation with both types of motor was about the same, the direct current motor had a distinct advantage in regulation when the speed was variable. On the whole, therefore, he was in favour of the use of a direct current system of electric supply.

Mr. Mordey, on account of lack of time, dealt shortly with the drop of pressure along the rails of an electric tramway, and stated that he had found that when the length was even 28 miles, the difference of potential between any parts of the rails and the generating station could be kept down to 7 volts; and he referred to the much greater attention that was given in England than in America to reducing the maximum drop of pressure along tramway rails. The employment of rotary transformers, as on the new Central London Railway, he deprecated as a makeshift, and suggested that, if the cost of all the transformers employed along the 6 miles of the route had been capitalised, it would have paid the company to have employed far thicker conductors. As regards the difficulty arising from the capacity of long underground cables traversed with alternate current, he pointed out that no difficulty in overcoming the effects of capacity had ever been met with in dealing with the 250 miles of underground cable in St. Petersburg. The Board of Trade had succeeded in using such instruments in their laboratory at Westminster that no interference could be caused by the construction of any electric tramway in the neighbourhood; therefore, he deplored the resistance that had been successfully offered a few years ago by a London college to the passing of a Bill for the construction of an underground electric railway near that college.

Mr. Mailloux pointed out that the small power-factor obtainable with alternate current motors, and the greater change in speed with a change in the E.M.F. that was experienced with alternate current than with direct current motors, was a serious objection to the employment of the former, and he instanced a case where the large current that was necessary for starting an alternate current motor had led him to adopt a direct current system in a sugar factory where 2000 horse-power was employed. The Fire Insurance Rules in the United States, which compelled the use of iron conduits, but which did not require that both the going and return conductors should be enclosed in the same iron tube—a condition, however, rendered necessary if alternate currents were employed—led to an important economy being obtained by using two separate conductors in separate iron tubes, which was, of course, quite possible with a direct current.

Prof. S. P. Thompson expressed his surprise that in wiring ships for electric lighting, where the possible disturbance of the compasses was a vital consideration, the direct current and two pole machines, the worst type to use, had been frequently employed even by the best firms, like that of Messrs. Siemens. He looked forward to seeing the use of multipolar machines on board ship, and of the alternating current; for not only would the compasses be then secure from disturbance, but there would be much greater freedom from electrolysis in damp places, and therefore of fire. He pointed out that the alternate current lent itself so readily to the use of efficient *low* voltage glow lamps combined with economic *high* voltage transmission; and finally that, since it was impossible to employ any device to screen a magnetic observatory from magnetic disturbance, since such a device would cut off the effects produced by variations of the earth's magnetism which the observatory existed to measure, there was a strong reason for running electric tramways with alternating current in any city where a magnetic observatory existed.

At the close of the preceding discussion, M. Hospitalier, Mr. Gavey, Mr. Hering and General Webber referred to points of special and novel interest in the several electrical sections of the Exhibition, in connection with which they had served as jurors; and in the afternoon these gentlemen acted as guides in taking parties of members of the two electrical societies to view the exhibits which had been specially mentioned.

## THREE BOOKS OF POPULAR NATURAL HISTORY.[1]

Mr. Hudson has never written any book that is not extremely pleasant to read, though since he settled in England he has never had so much to tell us as was told in his "Naturalist in La Plata." That book, though it may not be his own favourite, will always, if we are not mistaken, be reckoned as his best; and the reason is simply that it treated of animal life among which *he* was entirely at home, and of which *we* knew little or nothing. His English books have not this quality, though they have many other excellences. The one before us, for example, is charmingly written, full of grace and feeling, touched with a tender and sympathetic imagination, made piquant by a certain quite inoffensive egoism; but, as we read in his pages of the South Downs, we are forced to recognise the fact that he is not of them. He is a stranger there—a most appreciative one, it is true—but still a stranger. It is perhaps given to few who have not been bred among the Downs to enter fully into their spirit, and we will not deny that Mr. Hudson, rambling alone through their sweet air and lying on their delicious turf, has caught it as none could do without rare gifts of sympathy and observation; yet there is something missing.

It is not pleasant to have to find fault with a book so readable; but a naturalist cannot but regret that Mr. Hudson should have given himself up so entirely to *impressions* throughout a volume of just three hundred pages, that no real contribution to natural history is to be found in them. He notices an interesting point, writes a charming paragraph about it, and leaves it, sometimes without making it clear what plant or creature he is talking about. To take an example: he has observed that the banded variety of *Helix nemoralis* is almost the only one to be found on the high downs, and that its bright coloration does not save it from the thrushes; but he does not pursue this fact, which has attracted the attention of conchologists and suggested at least one interesting explanation. Snail life on the downs is, indeed, so extraordinarily abundant, that a book which contains so much pleasant reading about the down turf is hardly complete without a chapter specially devoted to it. The same may be said of his remarks on insect life; he tells us of the common blue butterfly, and its habit of clinging to the bents, but of other blues he says nothing; a skipper is mentioned, but we are left in the dark as to the species. In writing of a certain fly, he declares that neither books nor entomologists have been able to tell him its name, and leaves it with a few words of good-natured contempt for the specialism of the present age. A little more exactness in a book by a naturalist, which naturalists may be expected to read, would have greatly added to its permanent value. Even men of letters may complain when they find an allusion to Arthur Young's famous "Tour through Great Britain in 1727." What book can this be?

The best chapters are those which deal with the birds and the human beings of the downs. Shepherds and shepherd boys are delightfully pictured; and Mr. Hudson has discovered for himself the pleasing habit of the ruddy-faced shepherd lads in adorning themselves with wild flowers. About the birds he has plenty to tell us—it is his own subject; and the chapter on "Shepherds and Wheat-ears" will be read by all ornithologists with mingled pleasure and pain. All that he writes of the singers of the downland is beautiful and true; perhaps the songs of the stonechat and whinchat have never been so well described. Of the linnet, too, he says most truly that it has one note, and only one, of almost unapproachable musical beauty. The singing of the skylarks, that invariable accompaniment of down life, is described with all Mr. Hudson's wonderful sympathy and delicacy of language; but what are we to say of his belief that the highest notes of this bird may be heard on the downs at a distance of three miles? It is a belief which it would hardly be possible to test.

---

[1] "Nature in Downland." By W. H. Hudson. Pp. xii + 307. (London: Longmans, Green and Co., 1900.)
"The Birds of Cheshire." By T. A. Coward and Charles Oldham. Pp. 278. (Manchester: Sherratt and Hughes, 1900.)
"In Birdland, with Field-glass and Camera." By Oliver G. Pike. Pp. xvi + 280. (London: T. Fisher Unwin, 1900.)

"The Birds of Cheshire" is an excellent book of its kind. The first essential of such a compilation is that it should be unimpeachable as a record; and, so far as we can discover, the compilers have here used both pains and judgment in testing the records of others, while their own experiences are recorded simply and faithfully. Thus a real step is gained in the collection of valuable material for that comprehensive work on the distribution of birds in these islands which we may hope to see in due time. There is no superfluous matter in this volume, and no attempt at fine writing; and excellent paper, print and binding combine to make it a very pleasant book to handle. The half-dozen plates of Cheshire scenery are very effective, and nothing is wanting, unless it be a rather better map of the county.

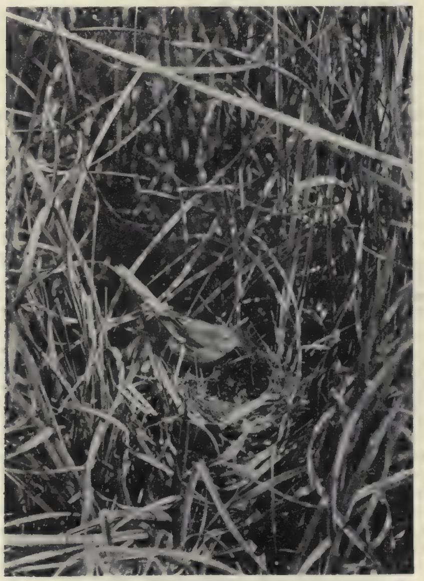

Fig. 1.—Bearded Tit feeding young.

The avifauna of Cheshire, as the authors remark, is surprisingly poor; the county does not lie upon any regular line of migration. It is too far north for the nightingale, which has seldom occurred, though we note that it has been recorded by that excellent observer, Rev. C. Wolley-Dod. The lesser whitethroat, as might be expected, is not common, nor is the grasshopper warbler. We should have expected the pied flycatcher to be more common than seems to be the case; the tree sparrow, a bird of peculiar distribution, has probably been often overlooked. The goldfinch and linnet are decreasing in numbers, but the opposite is the case with the turtle-dove. The list of waders, gulls, and birds of the coast, is not very large, and we regret to find that the ubiquitous golfer is contributing to its further diminution. The characteristic bird of the county is a noble one—the great crested grebe, which is widely distributed; and in dealing with it the authors have allowed themselves some half-a-dozen pages, which will be welcome to all ornithological readers.

Mr. Pike's little book bears the same relation to his photographs as a popular lecture does to its lantern illustrations: *i.e.* it is of secondary interest. Photography, applied to birds and their nests and eggs, seems to be a most attractive pursuit, leading its votary often to spend hours in the endeavour to catch a bird at some opportune and interesting moment, or to find the nest on which he has set his heart. It should certainly be useful in training the faculty of observation, and in assisting the memory; and it may become a most welcome substitute for the predatory habits of private egg-collectors, who are perhaps the most dangerous enemies of our rarer birds. The actual contribution to zoology, however, does not seem as yet to have been great, and it is quite possible that before long we may have too many books on the subject. Mr. Pike's is, however, so unpretending and so pleasantly written, that it will no doubt be welcome to many beginners in ornithology who wish to learn where and how to look for nests, and a few of his experiences and his photographs will be interesting even to the more experienced. Part iv., on Norfolk birds, is perhaps the most valuable section of the book, and of the three photographs which Mr. Pike succeeded in taking of the nest of the bearded tit we select one for reproduction, as a favourable specimen of his work.

## *THE INTERNATIONAL CONGRESS OF MATHEMATICIANS.*

A CONGRESS of mathematicians was held at Chicago during the World's Fair; but this was an isolated one. The series of international congresses was inaugurated at Zürich in 1897, and the second congress of this series met in Paris from the sixth to the eleventh of the present month. About 225 mathematicians of various nationalities, with 25 members of their families, were present. It had been expected that the numbers would be very much greater, as many as one thousand provisional acceptances having been received before last December; the diminished attendance was doubtless due partly to the great heat of the preceding month, but probably in greater measure to the fear of exhibition crowds and exhibition extortions. It had been supposed that the Exhibition would attract people to the Congress; on the contrary, it seems to have kept them away. The composition of the Congress was certainly international; the numbers of members from the different countries were approximately as follows:—France, 90; Germany, 25; United States, 17; Italy, 15; Belgium, 12; Russia, 9; Austria and Hungary, 8; Switzerland, 8; England, 7; Sweden, 7; Denmark, 4; the remainder being from South America (4), Holland, Spain, Roumania, Servia, Portugal, Turkey, Armenia, Greece, Canada, Mexico, Japan.

The actual business was preceded by a *réunion* at the Café Voltaire, on the evening of August 5, when about half the members were present. The proceedings proper consisted of two general meetings on Monday and Saturday, with sectional meetings on the four intervening days. The opening general meeting had been announced for 2.30 p.m., August 6, in the Palais des Congrès in the Exhibition grounds; but unfortunately some action on the part of the Exhibition authorities necessitated changing the hour to the morning, and this change was decided upon too late to be communicated to all the members, many of whom had not even arrived in Paris at that hour. Thus a considerable number of the members were unable to be present at the first general meeting, which was held on August 6 at 9.30 a.m. M. Hermite was acclaimed président d'honneur; M. Poincaré, president; the vice-presidents (some *in absentia*) were announced as MM. Czuber, Gordan, Greenhill, Lindelöf, Lindemann, Mittag-Leffler, Moore, Tikhomandritzky, Volterra, Zeuthen, Geiser. The secretaries were MM. Bendixson, Capelli, Minkowski, Ptaszycki, Whitehead; the general secretary, M. Duporcq.

M. Poincaré, on taking the chair, spoke a very few words of greeting, and then called upon the speakers of the day. M. Cantor, in his address, "Sur l'historiographie des mathématiques," sketched the development of this subject through Montucla (toujours un modèle que tout historiographe des sciences doit suivre), Kaestner, Cossali, Bossut, Chasles, Libri, Nesselmann, Gerhardt, Arneth, Hankel, Boncompagni, up to authors of the present day. He expressed the firm conviction that the history of mathematics, from the beginning of Lagrange's work, can only be written as a series of special histories, with a final volume (Histoire des Idées) coordinating the whole. M. Volterra, "Trois analystes italiens, Betti, Brioschi, Casorati, et trois manières d'envisager les questions d'analyse," compared and contrasted the work of these three mathematicians, and considered the influence their differing lines of thought and expression have had on the development of Italian analysis.

Six sections had been arranged, with meetings extending over four days. While in general two sections were sitting at the same hours, yet matters were so arranged as to avoid, as far as possible, the conflict of interests that had been felt at Zürich, where only one day was devoted to the sectional meetings. These six sections, with their presidents and secretaries, were as follows:—

(1) Arithmetic and Algebra: Hilbert, Cartan; (2) Analysis: Painlevé, Hadamard; (3) Geometry: Darboux, Niewenglowski; (4) Mechanics and Mathematical Physics: Larmor, Levi-Civita; (5) Bibliography and History: Prince Roland Bonaparte, d'Ocagne; (6) Teaching and Methods: Cantor, Laisant.

Owing, however, to the unavoidable absence on some days of the president of Section 5, and the small number of papers in that section, Sections 5 and 6 sat together, under the presidency, first of M. Cantor (Wednesday), and then of M. Geiser (Friday); and at the Wednesday morning sitting the two papers of most general interest in the Congress were read. These were Hilbert's address on the future problems of mathematics, valuable as assisting the mathematician to orientate himself, and Fujisawa's account of the mathematics of the old Japanese school, of special interest as giving information, not readily accessible otherwise, about a system of mathematics that is now entirely obsolete. It appears that the Japanese invented zero for themselves, and employed the circle as a symbol for zero; that they used imaginaries and complex numbers, and calculated the value of $\pi$ correctly to forty-nine places of decimals. In connection with this, M. Cantor remarked that the use of zero is probably Babylonian, and dates from about 1700 B.C.

M. Hilbert considered the origin and nature of the problems of mathematics the study of which is most likely to prove profitable; the characteristics of a proper solution; and the methods of attacking any problem that offers special difficulties. If the problem is really insoluble, then for the advance of mathematics it is essential that the impossibility be rigorously demonstrated. He illustrated his argument by means of selected problems that invite attack—problems regarding the axioms of arithmetic and of physics, prime and transcendental numbers, questions in the theory of functions, and the determination of the arrangement of the circuits that an algebraic curve can possess; referring to a paper about to appear in the *Nachrichten* der Kgl. Gesellschaft der Wissenschaften zu Göttingen, 1900, for a more complete list of definite problems that demand investigation.

Much interest was displayed in the papers read by M. Mittag-Leffler at the Tuesday morning sitting of Section 2, "Sur fonction analytique et expression analytique," "Sur une extension de la série de Taylor." The domain of an ordinary power-series is a circle that reaches to the nearest singular point; at all points inside this there is convergence, at all points outside there is divergence; this the author generalised so as to obtain a certain expression convergent within a particular region (an étoile), and divergent without. He raised the question whether an analytic expression can be found which shall represent, throughout its domain of definition, an assigned analytic function. A discussion followed between MM. Borel, Hadamard and Painlevé, as to the nature of the connection between "analytic expression in a complex variable $x$" and "analytic function in $x$." At the Thursday sitting of Section 1, M. Padé read a paper, "Aperçu sur les développements récents de la théorie des fractions continues"; in this he showed the dependence of the expression of a function of $x$ as a continued fraction on a certain diagram, in which each convergent is represented by a point whose co-ordinates are the degrees of the numerator and denominator of the convergent; and, referring to the discussion that followed Mittag-Leffler's paper, suggested that a continued fraction may be found to be a suitable analytic form for any assigned analytic function.

The Friday morning combined sitting of Sections 5 and 6 was to a great extent occupied by the discussion of a resolution offered by M. Leau, urging the Academy to consider favourably the adoption of a universal language, not with a view to displacing any of the existing languages, but as a scientific medium auxiliary to these. Some such resolution has been brought forward lately on several similar occasions by the advocates of the latest artificial language, Esperanto. The discussion showed, on the part of mathematicians, very little sympathy with the suggestion, and very little recognition of a need for any such medium. As one speaker remarked, mathematics already has a universal language, the language of formulæ; and the general sense of the sections was evidently that the existing diversity of languages need cause no real difficulty, so long as writers are willing to confine themselves to English, French, German and possibly Italian, this view of the case being formulated by a Russian, M. Vassilief. The only result of the discussion was the rejection of M. Leau's motion, and the recording of a wish that the Academy would discountenance any unnecessary diversity in the languages employed for scientific purposes. The four languages enumerated by M. Vassilief are those officially recognised in the meetings of the Congress, though it was noticeable that a great many of the speakers chose to speak in French, possibly out of compliment to their hosts.

Other communications of value, though of less general interest, were the following:—In Section 1, M. Stephanos, Sur la séparation des racines des équations algébriques; in Section 2, M. Tikhomandritzky, Sur l'évanouissement des fonctions $\Theta$ de plusieurs variables; M. Bendixson, Sur les courbes définies par les équations différentielles; M. Jahnke, Zur Theorie der Thetafunctionen von Zwei Argumenten; in Section 3, M. Lovett, On contact-transformations between the elements of space; M. d'Ocagne, Sur les divers modes d'application de la méthode graphique à l'art du calcul; M. Stringham, Orthogonal transformations in elliptic or in hyperbolic space; M. Jamet, Sur le théorème de Salmon concernant les cubiques planes; in Section 4, M. Hadamard, Relations entre les caractéristiques réels et les caractéristiques imaginaires pour les équations différentielles à plusieurs variables indépendantes; M. Volterra, Comment on passe de l'équation de Poisson à caractéristique imaginaire à une équation semblable à caractéristique réel; in Sections 5 and 6, M. Padoa, Un nouveau système irréductible de postulats pour l'algèbre; M. Capelli, Sur les opérations fondamentales de l'arithmétique. The attendance at these sectional meetings, all of which were held at the Sorbonne, varied from 50 to 120.

The concluding general meeting was held at the Sorbonne at 9 a.m. on Saturday. The proceedings opened with the sending of a message of greeting to M. Hermite, the président d'honneur of the Congress. It was then unanimously voted that the next Congress be held in Germany, in 1904, at the beginning or end of the summer vacation, the place mentioned as probable being Baden-Baden. M. Mittag-Leffler then delivered his address, "Une page de la vie de Weierstrass," and M. Poincaré spoke briefly on the "Rôle de l'intuition et de la logique en mathématiques," closing the proceedings immediately afterwards with the few words, "La séance est levée; le congrès est clos."

On the conclusion of the Tuesday afternoon sectional meetings, members were received at the École Normale Supérieure, where a pleasant opportunity for social intercourse was enjoyed; and at noon on the day after the closing of the Congress a banquet was held at the Salle de l'Athénée-Saint-Germain, when about 160 members sat down. In the absence of M. Poincaré, the proceedings were conducted by M. Darboux; speeches were made also by MM. Geiser, J. Tannery, Stephanos and Vassilief. A considerable number of members of this and other scientific congresses accepted the invitation of Prince Roland Bonaparte to a scientific *soirée* on Saturday. A *fête* had been arranged by President Loubet for Thursday evening, but could not be held on account of the funeral of the King of Italy; the invitations were consequently transferred to the *fête* in honour of the Shah on August 10.

It will be seen that very little business was transacted, apart from the reading of papers. At the joint sitting of Sections 5 and 6, it was asked what steps had been taken to put into effect the resolutions of the Zürich Congress as to the formation of a committee to consider certain questions of bibliography, &c., these having been adopted with the hope of ultimately consolidating mathematical enterprise, and directing it into profitable channels. No very satisfactory answer was forthcoming; M. Laisant, on behalf of the French Mathematical Society, replying that they had done nothing in this line, having been entirely occupied with making material provision for the Congress. He drew the attention of members, however, to the announcement of the *Annuaire des Mathématiciens*, undertaken by Carré et Naud, 3, Rue Racine, which is designed to be a complete register of all mathematicians, with their addresses. It is much to be hoped that these questions, raised at Zürich, will be dealt with in a business-like manner at the Congress of 1904.

---

## NOTES.

THE Scientia Club gave a banquet to Lord Kelvin during the International Physical Congress at Paris. M. Louis Olivier presided over a distinguished company, and speeches in appreciation of Lord Kelvin's scientific work were made by him and by Profs. Mascart and Cornu.

FROM the official report of the International Congress of Ælectricians at Paris, we see that two communications, by Mrs. Ayrton and M. Blondel, were received with great appreciation. Mrs. Ayrton's paper was on the luminous intensity of the electric arc with continuous current, and she showed that the best result, both from the point of view of luminosity and expenditure of energy, was obtained from an arc only a millimetre in length. Demonstrations in illustration of this conclusion, and showing the absorbing and cooling effects of carbon vapour produced in the arc, as well as the production and absorption of green and yellow radiations, were given by Mrs. Ayrton at a special meeting in the École supérieure d'Électricité. M. Blondel reviewed the progress of electric lighting during the past ten years, and made some very valuable remarks on arc lamps with alternating currents, and on the carbons commonly used in arc lights.

IN opening the business of Section A (Mathematical and Physical Science) of the British Association at the forthcoming Bradford meeting, we understand that Dr. Larmor will review the change of ideas which has recently become current regarding the scope and method of physical explanation. The brilliant experimental verification of Hertz has led to the acceptance on the Continent of the views originated in this country regarding the nature of electric actions and their dependence on the æther; but there has been a strong tendency to eliminate from the exposition of the theory those dynamical explanations which formed a main feature of its development in the hands of Clerk Maxwell. It is of fundamental importance to consider how far purely descriptive methods can thus avail towards an effective formulation of general physical theory, without appealing to a dynamical foundation of some kind. In all branches of the subject the discrete atomic constitution of matter is reached when we probe deep enough; thus the method of representation of the physical activities of the material atoms, so far as they can be known to us, is of the essence of a dynamical treatment. This leads on to the cognate question, whether denial of direct action at a distance necessarily implies the passing on of all electric effects from element to element of the medium entirely by simple stress; if that be too narrow a scheme, the efforts that have been made towards formulation on this basis were foredoomed to failure. The scope and limitations of the method of statistical enumeration of the activities of the atoms, which is the only one now available in ultimate thermodynamic discussions, depend on considerations of a different order. The modern extension of the range of the principle of Carnot also requires us to face the question how far the processes of chemical interaction between atoms, as distinct from the properties of the molecules when formed, are amenable to dynamical representation.—The general scheme for the business of the section is to take physical papers of a mathematical nature on Friday, September 7. On Monday, September 10, the section will divide into two, dealing with mathematics and meteorology respectively. On Tuesday a discussion on ions will be opened by Prof. Fitzgerald. It is also hoped to arrange discussions on the partition of molecular energy, and on the relation of radiation to temperature, under the thermodynamic aspect.

A PASTEUR Institute has just been opened at Kasauli, a hill station in the Punjab district, about thirty miles from Simla. It is thus no longer necessary for a person bitten by a rabid animal in India to journey to Paris for treatment by inoculation. The treatment at the Kasauli Institute is to be given free of charge.

PROF. J. C. BOSE, who has been attending the recent International Congress of Physics at Paris as the delegate of the Government of Bengal, will also attend the British Association meeting at Bradford in the same capacity, and will there describe some electrical investigations with which he has lately been engaged.

THE following international congresses upon scientific subjects will be held in connection with the Exposition at Paris during September: 3–8, History of Religion; 3–5, Basque Studies; 3–4, Pharmacy Specialities; 10–16, Meteorology; 10–12, Agriculture; 10–12, Folklore; 13–14, Fish Culture and Arboriculture; 14–19, Agriculture and Fisheries; 15–20, Aeronautics; 22–28, Acetylene.

PROF. GIARD, director of the biological station at Wimereux, has been made Chevalier of the Order of Leopold by the Belgian Government, as a recognition of the hospitality which he has extended to Belgian students and naturalists at his laboratory for many years.

DR. J. W. B. GUNNING, the director of the State Museum at Pretoria, speaks in high terms of the way in which he has been treated by the new British authorities. He has not only been confirmed in his post at the museum, but also materially assisted in his efforts to add to it a zoological garden, which he had planned before the outbreak of hostilities. It was to this (incipient) garden that the celebrated lioness (now in the Regent's Park Garden) was presented by Mr. Rhodes, but subsequently returned to the donor by Mr. Kruger's order.

AN international association for the promotion of psychical research has been established under the title: Société internationale de l'Institut Psychique. A *Bulletin* has been issued containing a report of the inaugural meeting held at Paris on June 30, and explaining the objects of the organisation. The Comité de Patronage includes the names of Prof. Mark Baldwin, Prof. W. F. Barrett, Sir William Crookes, Prof. O. J. Lodge, and Mr. W. H. Myers. The general secretary is M. Yourievitch, Russian Embassy, Paris.

A MONUMENT to Bertrand Pelletier and J. B. Caventou, renowned as pharmaceutical chemists, was unveiled at Paris, by M. Moissan, during the recent International Congress of Pharmacy. Caventou was born in 1795, and studied at the Paris School of Pharmacy. While pharmacist at the St. Antoine Hospital he met Pelletier, and their fruitful collaboration began. Two years after discovering brucine and strychnine they were able to announce the discovery of quinine, and with rare disinterestedness they made their work public by presenting an account of their methods and results to the Paris Academy of Sciences on September 11, 1820. In their memoir they stated that they had succeeded in isolating cinchonine and quinine from both yellow and red cinchona bark, and described the therapeutic properties of these substances. In 1827 the Montyon prize of the Academy of Sciences was awarded to them in recognition of their valuable discovery, and now the monument, representing the two investigators together, stands to remind observers of their joint services to science and humanity.

THE International Meteorological Congress will be opened at Paris on Monday, September 10, under the presidency of M. E. Mascart, and will continue during the week. The International Meteorological Committee, which met last year at St. Petersburg, decided that it would convene, at the same time as the Congress, the various committees appointed by the Paris Conference in 1896. These committees are the following:—(1) Terrestrial Magnetism and Atmospheric Electricity. (2) Aeronautics. (3) Clouds. (4) Radiation and Insolation. The first of these committees held an important meeting at Bristol in 1898, the proceedings and resolutions of which have been published in the reports of the British Association. A great number of ascents, both with free as well as captive balloons, have been made in different countries, for the systematic investigation of the upper regions of the atmosphere. Finally, the publication and discussion of the international observations of clouds, made in 1896–97, will probably be completed in 1900 in the majority of the countries taking part in the same. From this it will be seen that communications of very high interest will be brought before the Congress. The questions which will be dealt with are not restricted exclusively to meteorology properly so-called: they will include, generally, everything which affects the physics of the globe. The meetings of the Congress and of the committees will be held at the House of the Société d'Encouragement, 44, Rue de Rennes, where the International Conference met in 1896. Communications relating to the organisation or to the programme of the Congress should be addressed to Mons. Angot, general secretary, 12, Avenue de l'Alma, Paris.

A REUTER telegram, dated Madrid, August 24, states that twelve fragments of a meteorite have fallen on the boundary of the provinces of Jaen, Cordova and Granada. The fall was preceded by a series of loud detonations. One fragment, weighing about a pound, which was picked up at Val, in the province of Jaen, is said to be of hexagonal shape, grey on the surface, and of a greenish colour inside.

As attempts are being made to found a domestic science, and to introduce exactitude into the operations of the kitchen, a note in the *Monthly Weather Review* recording the actual experience of a housekeeper at Albuquerque, New Mexico, is of interest. It appears that cooking recipes and practices which are trustworthy not far from sea-level are worthless at Albuquerque, the altitude of which is 4933 feet. Water boils there at 202° F., instead of 212° F.; hence articles of food, the cooking of which depends upon heat applied through the medium of water, require a longer time for cooking than is given in the cookery books. On account of the extreme dryness of the atmosphere, farinaceous foods, such as beans, corn, &c., lose so much of their moisture that they have to be left for a long time in water before cooking, in order to be softened. But the worst difficulty is with cake-making. Ordinary recipes as to number of eggs and amount of baking powder break down altogether, and housekeepers have to modify them if they wish their operations to be successful. As the barometric pressure determines to what extent the disengaged carbon dioxide shall expand and aerate the dough, this may explain the different action of baking soda and egg batter. In any case, the observation is interesting, and chemists may find it worthy of their attention.

*La Nature* of August 18 contains an article, by M. E. Roger, director of the meteorological station at Châteaudun, near Paris, entitled "The Greatest Heat of the Century." A temperature of 103°·6 in the screen was observed there on July 27 of this year. The nearest temperature to this hitherto recorded in the vicinity of Paris during the last hundred years was 101°·5 at Montsouris Observatory on the 20th of the same month. At Poitiers in July 1870, a temperature of 106°·2 was recorded. Among the highest temperatures recorded in or near London are 95°·2 at the late Mr. Symons' station, Camden Town, on July 16 last, and 97°·1 at Greenwich in July 1881; in that month a reading of 101° was obtained at Alton, Hants.

THE Pilot Chart of the North Atlantic Ocean for August, issued by the U.S. Hydrographic Office, contains a diagram showing the path of the noteworthy cyclonic tropical storms of the years 1898 and 1899, together with the time of their duration, which varies from 2 to 39 days; two of the storms were traced entirely across the Atlantic. Taken collectively, the several tracks exhibited show the doubtful accuracy of generalised statements concerning certain characteristics of these storms, such as their velocity, the latitude of their recurvature, &c. Thus the statement is often made that in the higher latitudes, after recurvature, the velocity along the track will average 25 or 30 miles an hour. However true this may be as the statement of an average, its untrustworthiness with regard to a particular storm is well shown by one of the tracks laid down, in which the velocity of the centre after recurvature off the coast of Florida fell to about three miles an hour through three degrees of latitude.

We have received a copy of the meteorological observations made at Sir Cuthbert Peek's observatory at Rousdon, Devon, for the year 1899, the sixteenth year of the series. This observatory is a second order station of the Royal Meteorological Society, and possesses a very complete equipment of instruments, both astronomical and meteorological, including various patterns of standard anemometers, the observation and comparison of which form a special and valuable feature of the regular work of the station. The mean temperature of the year exceeded the average by more than 2°; but the year was free from extremes in either direction, although at Greenwich on August 12 a temperature of 90° was recorded. The rainfall was about two and a half inches below the average, and amounted to only 29·31 inches; falls of an inch or more occurred on five days. A daily comparison is made between the actual weather and the forecasts of the Meteorological Office; as regards wind, the percentage of success has increased from 69 in 1884 to 93 in 1899, and in the case of weather, from 73 to 92 in the same period.

The following notes from a report by Mr. H. A. Byatt, assistant collector, Fort Alston, are published with others in the *British Central Africa Gazette*:—"After passing over the ridge of hills which culminates about two miles to the east of Ndonda, some forty miles from the lake shore, the appearance of the country and the nature of its soil changes very considerably. In place of the low-lying marshy expanses along the coast, one finds a monotonous series of undulating grassy plains, covered almost exclusively with a growth of tall rank grass. The soil generally, though occasional small deposits of clay are found, consists of a layer of coarse porous sand, apparently of no great depth, lying upon a substratum of hard rock, and may well have been washed down by centuries of rain from the low hills above mentioned. The country is remarkably waterless. Judging by the appearance of the vegetation which it supports, the soil is of poor quality, and offers but little hope of successful cultivation. Large timber is conspicuous by its absence, and it is only at rare intervals that the raphia-palm and other trees requiring a copious supply of moisture are found; but possibly such woods as the Mlanje cedar might be introduced with success. Owing to the rank growth of grass, it is an ideal cattle country; but the true reason of the excellent condition of cattle in this country is to be found, I believe, in the presence of a certain salt in the earth—possibly a nitrate or phosphate of soda. In many places itis so abundant that upon the evaporation of the water it is left as a thick white deposit on the surface of the soil, whence it is gathered up by the natives and used as a condiment. Of other minerals, beyond the existence of graphite, I have so far found no trace."

The progress of work on the new wheel-pit of the Niagara Falls Power Company, at Niagara Falls, N.Y., which is intended to supplement the present hydraulic installation of the same company, is described and illustrated in the New York *Electrical Review* (August 15). It is only a few years since the company began operations with a plant capable of being extended to 50,000 horse-power. Both the rapid growth of electrochemical industries at Niagara, and of electric power applications in Buffalo, twenty-six miles away, have rapidly carried the plant up to the limit of its former hydraulic equipment. Now the new one, which is slightly larger than the old, is under construction, and it is expected that within a year 105,000 horse-power will be generated and distributed from this one plant. The growth of such industries in the United States has been extraordinary. In New York State there is another plant under construction which will be finished within a year, and will develop the enormous total of 150,000 horse-power. Practically all of the latter installation will be used in electrochemical work in the manufacture of carbides and caustic and bleaching powder.

The manufacture of artificial dye-stuffs in Germany was referred to in a recent report from H.M. late Consul-General at Frankfort-on-Main. The endeavours of manufacturers and industrial chemists are directed, generally speaking, to producing the organic natural products, such as those of colour plants, dye woods, insects, molluscs, &c., by artificial and even cheaper and purer means, and in a more serviceable form for dyeing; also to producing new colours, which not only approach in brilliancy and effectiveness the natural kinds, but even surpass them. Since the discovery that the important dye-stuff madder—alizarine—could be produced in an easy and cheaper manner from the carburetted hydrogen of coal-tar, the use of dye-stuffs obtained by coal-tar distilling has gradually grown to such an extent that in Germany about five times as many artificial colours are made as in all other countries combined. According to the census in 1895, there existed twenty-five factories for the manufacture of aniline and aniline colours, and forty-eight factories (with seven branches) for the production of other coal-tar products (*i.e.* not only for colours, but also for other commodities, such as picric acid, &c.). The aniline works employ 7266 hands, the latter factories 4194; in all, 11,460 men.

In connection with the foregoing note, the *Board of Trade Journal* gives some particulars as to the manufacture of artificial indigo in Germany, from a report to the Foreign Office. The importance of indigo is evidenced by the fact that the production of natural vegetable indigo equals in value the entire world's production of artificial dye-stuffs. The present artificial indigo of commerce represents almost pure indigotin. It is sold in the form of a 97 per cent. powder, whereas the indigotin contained in vegetable indigo fluctuates between 70 and 80 per cent. It contains no indigo-red, no indigo-brown and no indigo-blue. The lack of indigo-red and indigo-blue, which both seem to be of some importance in the relation of the dye-stuff to the fibre, are its special disadvantages. The indigo-red seems to be of importance in the production of darker shades of colour. There is no doubt that at some time not too far off it will be possible to produce this ingredient also. Artificial indigo is used by dyers in the same way as vegetable indigo. If it is possible to render the process of manufacture materially cheaper, and thereby to considerably reduce the price of artificial indigo, the danger to natural indigo will be greatly increased; it is, indeed, to be feared that with the increase of chemical knowledge the same fate awaits this dyeing plant, which is extensively cultivated in British territories, as overtook the Krapp plant, the cultivation of which nowadays no longer pays. Artificial indigo affords a new example of the manner in which applied science revolutionises the most varied spheres and destroys as well as creates great wealth.

The *Atlantic Monthly* for August contains an account, by Mr. Sylvester Baxter, of a method devised by Mr. Arthur J. Mundy, whereby a ship may be guided into port in stormy weather which prevents ordinary signals from being of service. The method is called "Acoustical Triangulation." It is based on the property that sound travels under water with a velocity that is unaffected by the disturbances such as winds, which have so large an influence on the propagation of sound-waves in air; and the putting of this principle into practice depends on the invention of a successful apparatus for ringing a bell under water by electrical connections. Three bells placed at the corners of a triangle, preferably equilateral, are sounded at known intervals of time. By noting the intervals of time between the instants when the first and second bells are heard, the locus of the ship's position is known to be one of the branches of a certain hyperbola the foci of which are the two bells. By noting the apparent interval between the second and third bell, the ship is similarly located on another hyperbola, and the intersection of the two curves gives the required position of the ship. The only objection to the method appears to us to be that a pair of hyperbolic branches may intersect in *two* points, so that for given intervals between the bell sounds the position of the ship may be ambiguous. This could be avoided by having four bells instead of three.

AT the annual meeting of the Physical and Natural History Society of Geneva, Prof. A. Pictet surveyed the work which had been brought before the society during 1899. Eighteen meetings were held, and no less than seventy-three communications or reports were read. M. F. L. Perrot and Prof. Guye have made a series of measures of surface tension of various liquids by the method of falling drops. The conclusion arrived at as a result of their observations was that these tensions are not proportional to the weight of the drops. A new recording telephone was described by M. F. Dussand. M. T. Tommasina has studied the variations of conductivity of coherers, and M. E. Steinmann has contributed a note on the thermo-electricity of various alloys. To the section of chemistry and mineralogy, M. Louginine has contributed an important memoir on the latent heat of evaporisation of some organic liquids; MM. Dutoit and Friderich have determined the molecular weights of some organic liquids by the method of capillary ascensions; Prof. A. Pictet and M. Athanasescu have presented a note on the constitutional relation between two alkaloids of opium-papaverine and laudanine; M. Duparc has described his researches on the Liparite rocks of Algeria; and M. H. Auriol has made a detailed study of the agricultural soils of the Canton of Geneva. In the section of botany, M. de Candolle stated that grains of wheat which he had kept for four years under mercury had germinated and produced normal plants; and Prof. Chodat has described several micro-organisms of plants. Among the subjects of papers contributed to the section of zoology and anthropology are the development of the wings of Lepidoptera, by M. A. Pictet; and a comparative study of a series of skulls from old burying-places in the Valais district, by M. Pitard. In the section of physiology and medicine, Prof. J. L. Prevost and Dr. Battelli have described their detailed researches on the action of electric currents upon animals; and M. Babel has given an account of his work on the comparative toxicology of aromatic amines.

THE present trend of legislation in the interests of fish preservation in the United States is, Dr. Whitten remarks (*State Library Bulletin*, No. 12, New York), to place more reliance on methods of fish propagation than on a multiplicity of vexatious restrictions, and to obtain through scientific research the knowledge essential to enlightened regulation. In 1871 the United States commission of fish and fisheries was created to undertake scientific investigations, collect information, and to further the introduction and multiplication of food fishes, particularly in waters under national jurisdiction. In 1898 the commission maintained 34 fish-cultural stations and distributed 857,509,546 eggs, fry and adult fish. Fish commissions have been created in every State except Kentucky. Many of the commissions exist primarily for protective purposes, but others carry on valuable scientific work and maintain hatcheries and stock local waters with the most valuable food fishes. Illinois has a zoological station, and Oregon has created the office of State biologist for the investigation of the animal resources of the State and the development of such as have economic value.

THE relation of the cell to the enzymes, or soluble ferments which originate from cells, was touched upon by Sir J. Burdon-Sanderson, Bart., in the address he delivered before the recent International Medical Congress at Paris. Formerly, he pointed out, each kind of cell was regarded as having a single special function proper to itself, but the progress of investigation has shown that each species of cell possesses a great variety of chemical functions and that it may act on the medium which it inhabits, and be acted upon by it, in a variety of ways. Thus, for example, the colourless corpuscles of the blood (or, as they are now called, leucocytes) are considered not merely as agents in the process of suppuration or as typical examples of contractile protoplasm, but rather as living structures possessing chemical functions indispensable to the life of the organism. Similarly, the blood disc, which formerly was thought of merely as a carrier of hæmoglobin, is now regarded as a living cell possessed of chemical susceptibilities which render it the most delicate reagent which can be employed for the detection of abnormal conditions in the blood. The tendency of recent research is to show that the reactions referred to as chemical functions of the cell (action of the cell on its environment—action of the environment on the cell) are the work of ferments—intrinsic or extrinsic—which are products of the evolution of the living cell, and therefore to which the term enzymes may be applied.

RECENT researches have plainly indicated that in the case of the disease-producing micro-organisms, the specific functions which for years were regarded as proper to, and inseparable from, the cell belong essentially to the enzymes which they contain. It has been further shown that similar statements can be made as regards ferment-processes which differ widely from each other and no less widely from those induced by bacteria. So that in the domain of microbiology the enzyme may in a certain sense be said to have "dethroned the cell." For if, as M. Duclaux has said, it is possible to extract from the cell a substance which breathes for it, another which digests for it, another which elaborates the simple from the complex, and finally another which reconstitutes the complex from the simple, the cell can no longer be considered as *one*, but rather as a complicated machine, the working of which is for the most part dependent on enzymes, which, however numerous and varied may be the processes in which they are engaged, all follow and obey the universal law of adaptation, and all contribute to the welfare and protection of the organism.

IN our last week's issue reference was made to Dr. Haller's views as to the relationships of the different groups of the Vertebrata, based on his study of the hag-fishes and lampreys. And in the July number of the *Journal of Anatomy and Physiology* the subject of the origin of Vertebrates, as deduced from the study of the larval lamprey (Ammocœtes), is resumed by Dr. Gaskell. In this important communication the author arrives at the conclusion that Ammocœtes is a representative of the Devonian Cephalaspids, and also that a larval form of the latter group must have existed which was of the nature of the Eurypterid Crustaceans. Again, judging from the development of Limulus, it would appear that the larval Eurypterid resembled a Trilobite, and there is evidence that Trilobites are Phyllopods, which are almost certainly derived from Chætopod Crustaceans. Admitting the derivation of the lampreys from Cephalaspids, we find that the latter, in their adult condition, approximate to larval Amphibians; and we hence pass from the latter to the lower Mammals, and so on to Man. Thus, according to Dr. Gaskell, the study of Ammocœtes, owing to the importance of larval forms, enables us to bridge the gulf between the Annelid and Man.

THE greater portion of the July number of the *Quart. Journ. Microscopical Science* is occupied by a communication from Messrs. F. W. Gamble and J. H. Ashworth on the anatomy and classification of the Sandworms (Arenicolidæ). This is followed by a most interesting series of diagrams illustrating the life-history of the parasites of malaria, by Messrs. Ross and

Fielding-Ould, accompanied by a short explanatory text. The diagrams were originally intended to illustrate a lecture delivered at the Royal Institution, to which reference is made in NATURE of March 29. The authors adopt the name Hæmamœbidæ for the intracorpuscular amœba-like bodies which occur in the blood of certain animals. Of these, three species occur in human beings (producing the various types of malarial fever), one in monkeys, three in bats, and two in birds. Only the human and avian forms are illustrated. The development of four of these has been followed in gnats; the three human forms living in Anopheles, while the bird-infesting species dwells in the common *Culex pipiens*. To this paper Prof. E. Ray Lankester appends a separate communication describing the generative process in the aforesaid "Hæmamœbids" and in the allied Coccidiidæ, which are parasitic in cuttle-fish. Sexual conjunction, or "zygosis," has recently been demonstrated to occur in the former group, and shortly before certain peculiar bodies known as microgametes and macrogametes were found to occur in the latter. These Prof. Lankester now shows respectively correspond to the spermatozoa and ova of higher organisms, specimens of the Coccidiidæ being figured in which the process of fertilisation by the microgametes is actually taking place.

TO vol. xiii. Part 1 of the *Annals* of the New York Academy of Sciences, Prof. H. F. Osborn contributes an important paper on the correlation between the Tertiary mammalian horizons of Europe and America. The author is of opinion that the Puerco Eocene of the United States has no parallel in the European series, and that the Egerkingen beds of Switzerland are newer than the Wasatch. The three main divisions of the European Miocene are correlated with the Loup Fork and a portion of the John Day groups of America. But the most generally interesting portion of the paper is that in which Prof. Osborn enunciates his views with regard to former land connections. The theory of an extensive Antarctic continent synchronously connecting South America and Australia, and also communicating at some epoch with Africa, is deemed to be demonstrated. And it is considered that South America has experienced four distinct streams of faunal migration. In the first it received its peculiar Ungulates and Edentates; in the second it yielded the ancestors of Aard-varks, Pangolins, and perhaps Hyraces, to Africa; during a third land connection Marsupials immigrated from Australasia; and in the fourth the modern North American types effected an entrance. In contradistinction to the general view that Africa received its fauna from the north, the author is of opinion that the Dark Continent was itself the great dispersing centre and theatre of evolution; but whether South America received its original fauna from Africa or from North America is left an open question.

AMERICAN zoologists continue to devote their attention to the mammals of the Old World; and in the *Proceedings* of the Washington Academy of Sciences for July, Mr. G. S. Miller publishes two papers on the squirrels of Siam and Malacca, as well as a third on the European red-backed field-mice. Mr. Bonhote has just been writing on the former subject in the *Annals of Natural History*, and it seems a pity that naturalists cannot agree to divide their work so as to avoid overlapping and consequent unnecessary multiplication of names.

THE *Zoologist* for August contains an interesting account of a visit to Lundy Island during the nesting season, by Mr. F. L. Blathwayt. In the course of the paper allusion is made to the tradition that the Great Auk, or some equally large unknown bird, formerly inhabited the island. Only one or two pairs of this bird were known to the islanders, but an egg (subsequently broken) was secured in 1839. This subject seems worthy of further investigation.

WE are glad to see that in its September issue the *Girl's Realm* is endeavouring to awake an interest in the animal life of the sea-shore among its numerous juvenile readers, by publishing an illustrated article, entitled "An Hour in a Drang," by Mr. E. Step. "Drang," we learn, is Cornish for a deep cleft; and in his admirable description of such a cleft among the rocks at low tide, the author introduces his young friends to its living inhabitants in such a delightful manner that he can scarcely fail to gain many converts to the study of natural history. The photographs of crabs and lobsters with which the article is illustrated are admirably presented.

A *Bulletin* (Technical Series, No. 8) just issued by the U.S. Department of Agriculture (Division of Entomology) contains contributions towards a monograph of the American Aleurodidæ, by Mr. A. L. Quaintance, and a paper on the Red Spiders of the United States (Tetranychus and Stigmæus), by Mr. Nathan Banks. We have only one or two species of the interesting homopterous family Aleurodidæ in England. They are garden insects, which have a superficial resemblance to small white moths. In the present monograph forty-two American species of Aleurodes (Latreille) are described, most of them for the first time, and ten others belonging to the genus Aleurodicus (Douglas). To these the plates refer. The second paper, which is illustrated by wood-cuts, relates to the mites improperly called Red Spiders, which are equally troublesome in gardens and greenhouses in Europe and America. Of the two genera here discussed, ten species of Tetranychus (Dufour) and one of Stigmæus (Koch) are described; several as new. It is rather a pity that the term entomology is used in England so narrowly as practically to exclude mites, spiders, centipedes, &c., from entomological publications, and thus to hinder the popularisation of knowledge respecting them. In America, entomology is given the wider extension which it possessed at the beginning of the century, as may be seen by the inclusion of mites in the present publication.

THE members of the Manchester Microscopical Society deserve a word of encouragement for the efforts they make to extend a knowledge of natural history. One section of the society is entirely concerned with this work, and the members of it propagate the gospel of natural history by lecturing and demonstrating wherever their services are required. A programme containing a list of nearly fifty subjects has been issued, and the honorary secretary, Mr. George Wilks, 56, Brookland Street, Eccles New Road, Manchester, will arrange for lectures or demonstrations upon any of them if a communication is made to him.

THE two last numbers of the *Bulletin* of the Free Museum of Science and Art of Philadelphia show that this institution is growing rapidly under the care of Mr. Culin. The more important recent additions are figured. In vol. ii. No. 3 is an account of the historical Dickeson collection from the Mississippi mounds, and in the following number is a descriptive catalogue of the Berendt collection of books and manuscripts on the languages of Central America in the Museum Library, carefully compiled by the late Dr. Brinton.

THOSE interested in the decorative art of primitive folk should consult two fully illustrated papers in the *American Anthropologist* (N.S. vol. ii. No. 2, 1890). One, by Mr. R. B. Dixon, deals with basketry designs of the Maidu Indians of California, in which animal and plant forms, feathers, arrow heads, mountains and clouds are plaited in a very conventional manner. The author makes the significant remark, "The knowledge of the designs is almost exclusively confined to the older women, the younger generation knowing only very few." The second paper is one by Mr. B. Laufer, on the Amoor tribes, and is a preliminary account of the work done by this observer on the Jesup North Pacific

Expedition. Mr. Laufer gives a careful analysis of zoomorphic patterns, mainly of the Gold tribe; their decorative art shows distinct traces of Chinese influence, but the designs have been evolved in an original and interesting manner.

THE catalogue of bacteriological and pathological apparatus, just published by Messrs. J. J. Griffin and Sons, contains several new instruments and accessories, and will well repay inspection. Among the apparatus we notice several spirit Bunsen burners, which can be used instead of ordinary Bunsen burners where gas is not available. These are, of course, suitable for any laboratory, and not merely for bacteriological work. Of special interest are a number of new centrifuges for use in the examination of blood, sputum, milk. In water, urine and milk analysis a comparatively low rate of revolution is required, and a hand centrifuge giving up to 2000–3000 revolutions a minute is sufficient. When examining blood or sputum it may be necessary to make upwards of 10,000 revolutions a minute, which rate can be obtained by a water-power centrifuge manufactured by Messrs. Griffin. Another noteworthy addition is a special test-tube possessing characteristics always required for bacteriological work, but rarely found.

THE additions to the Zoological Society's Gardens during the past week include a Javan Mynah (*Gracula javanensis*) from Malacca, presented by Mr. George Smith; an Indian Crow (*Corvus splendens*) from India, presented by Mr. E. A. Williams; a Rose-coloured Pastor (*Pastor roseus*) from India, an Indigo Finch (*Cyanospiza cyanea*), a Nonpareil Finch (*Cyanospiza ciris*) from North America, presented by Mr. L. Ingram Baker; a Raven (*Corvus corax*), European, presented by Mr. G. St. Leger Hopkinson; three Blackish Sternotheres (*Sternothoerus nigricans*) from Madagascar, two Prasine Snakes (*Coluber prasina*) from Upper Burmah, eleven American Box Tortoises (*Cistudo carolina*) from North America, deposited; an Occipital Blue Pie (*Urocissa occipitalis*) from the Western Himalayas, ten Common Chameleons (*Chamaeleon vulgaris*) from North Africa, purchased; a Brush-tailed Kangaroo (*Petrogale penicillata*), born in the Gardens.

## OUR ASTRONOMICAL COLUMN

ASTRONOMICAL OCCURRENCES IN SEPTEMBER.

Sept. 1. 8h. Jupiter in conjunction with the moon. Jupiter, 0° 51′ North.
3. 7h. 16m. to 8h. 11m. Moon occults the planet Saturn.
4. 7h. 35m. to 8h. 50m. Moon occults the star $\xi^1$ Sagittari (mag. 5·0).
5. 7h. 24m. Transit (ingress) of Jupiter's Sat. III.
12. 12h. 35m. to 13h. 43m. Moon occults $\pi$ Arietis (mag. 5·6).
12. 16h. 27m. to 17h. 40m. Moon occults $\rho^3$ Arietis (mag. 5·5).
13. 9h. 43m. to 10h. 34m. Moon occults 13 Tauri (mag. 5·4).
14. 8h. 39m. to 9h. 18m. Moon occults D.M. + 20°, 785 (mag. 5·8).
15. Venus. Illuminated portion of disc = 0·493.
15. Mars. " " " = 0·915.
16. 12h. 8m. Minimum of Algol ($\beta$ Persei).
17. 6h. Venus at greatest elongation. 46° 1′ West.
18. 14h. 48m. to 15h. 40m. Moon occults 29 Cancri (mag. 5·9).
19. 8h. 57m. Minimum of Algol ($\beta$ Persei).
23. 0h. Sun enters Libra, autumn commences.
27. Saturn. Outer minor axis of outer ring = $17''\cdot25$.
28. 21h. Jupiter in conjunction with the moon. Jupiter, 0° 13′ North.

RING NEBULA IN LYRA.—It is interesting to find in the *Bulletin* de la Société Astronomique de France, August 1900, an account of the first published work done with the great 50-inch refractor of the Paris Exposition while that exhibition is still in progress. M. Eugène Antoniadi, of the Juvisy Observatory, has been for some time making systematic observations of nebulæ with the instrument, and a drawing showing a considerable amount of detail accompanies his paper on the Ring Nebula, the first of the series he has undertaken to study. He mentions that the lens used is the photographic one, the other, specially corrected for the visual rays, not yet being in position. The focal length of this glass is about 186 feet (57 metres).

OCCULTATION OF SATURN.—On Monday evening next, September 3, there will be an occultation of Saturn by the moon, for which the following particulars for Greenwich may be useful:—

| | Sidereal Time. | | Mean Time. | | Angle from | |
|---|---|---|---|---|---|---|
| | h. m. | | h. m. | | North point. | Vertex. |
| | | | | | ° | ° |
| Disappearance ... | 18 6 | ... | 7 16 | ... | 128 ... | 126 |
| Reappearance...... | 19 1 | ... | 8 11 | ... | 217 ... | 206 |

Providing the weather be favourable, this should be an excellent opportunity for observing the occultation of the planet, as the altitude will be almost at its maximum, meridian passage at Greenwich occurring at 7h. 7m. G.M.T. Moreover, from its being such a bright object, observations may be made with instruments of the lowest optical power.

In the *Bulletin* de la Société Astronomique de France for August 1900, M. M. Honorat gives an illustrated description of his observation of the last occultation of Saturn on June 13. He mentions the conspicuous contrast between the slightly yellowish colour of the moon and the greenish tint of the planet. During the occultation the planet appeared separated from the lunar limb by a narrow shadow about 5″ of arc in width, probably a contrast effect.

At the reappearance of Saturn at the terminator, he could not perceive any trace of penumbral shadow cast on the planet's disc.

OPPOSITION OF EROS.—Two additional circulars have been issued by the special committee appointed by the Astrographic Conference to direct the observations of Eros during the coming opposition. Special attention is drawn to the work which may be commenced at once, such as micrometric observations with all equatorials of large aperture, for furnishing definite positions for the theory of the planet's movement, and that these should be published as soon as possible, to perfect the ephemerides for the actual parallax work later. An ephemeris is included from the computations of M. Millosevich, and tables showing the limiting times between which the planet will have an altitude greater than 20° at various latitudes, and also a table indicating the proper regions to be included on the photographs on dates extending from September 19 to January 7.

In the *Astronomische Nachrichten* (Bd. 153, No. 3656), Prof. S. J. Brown, of the U.S. Observatory at Washington, calls attention to the many opportunities for simultaneous micrometer observations at widely separated stations, and as many observatories are not equipped with the photographic instruments necessary for the more general programme contemplated, gives data for assisting micrometer observers to co-operate for this type of work alone. The high declination of the planet makes it possible to secure simultaneous observations at all the Eastern stations west of Pulkowa, and at all the American observatories east of Denver. He also gives a table showing the Greenwich Mean Time at which the planet will be simultaneously visible at the observatories of Pulkowa, Königsberg, Vienna, Evanston, Madison, Yerkes and Denver for intervals of ten days from 1900 October 1–1901 January 19. Careful sketches of the comparison stars in the field should be made to facilitate subsequent identification. Owing to the rapid orbital motion of Eros rendering observations for position angle and distance very troublesome, measures should be made in rectangular co-ordinates referred to the true equatorial position of the fixed micrometer wire.

## THE INTERNATIONAL PHYSICAL CONGRESS.

THE first International Congress of Physics, which has just finished its sittings, has been a brilliant success. The number of participators exceeded a thousand, and, in spite of the attractions which Paris always offers, in spite of the simultaneous rivalry of the Universal Exhibition itself, sectional and general meetings were closely followed up to the last day by a great number of visitors.

The cause of this unexpected success must no doubt be sought in the idea underlying the plan of the Congress, worked out as it was with the greatest care by a committee of the Société Française de Physique. That committee deliberately rejected the method of simply presenting personal memoirs, or notes on limited subjects, and concentrated all its efforts upon the preparation of a well-arranged summary of the actual state of physical science, in the branches in which, within the last few years, the greatest progress has been made, and the actual stage of progress of which at the end of the nineteenth century it was considered most important to investigate. Once the list of subjects was completed, the work was divided among the physicists who seemed best qualified to give a complete representation of their special subject. This plan gave rise to a series of reports,[1] many of which are works of a very high value, and which, in their entirety, constitute the most complete representation of any science at a given epoch yet made. These reports number about 80. To summarise these here would be, so to speak, repeating the work of the Congress on a small scale, and that could not be thought of. I shall, therefore, confine myself to referring to them by groups which are obviously related and mutually supplement each other.

For this considerable task, a preface was necessary. M. H. Poincaré provided such a preface, and brought it before the Congress amid great applause, showing how mathematical generalisation could render experimental work infinitely more fertile. Experimental physics is a library. Mathematical physics arranges it and prepares the catalogue. It does not enrich it, but if it is well prepared it enables one to draw a greater profit from the former. The celebrated mathematician then showed how hypotheses have succeeded each other, in the form of physical images or simply mathematical images, where the symbol often remains true even when the mechanism is no longer accepted. Mathematical analysis also alone gives the true sense of the simplicity hidden under complexity, as in the case of Newton's law—which is always rediscovered in the most complicated movements of the heavenly bodies—or the kinetic theory of gases, where the law of large numbers hides the isolated individuals, only permitting the appearance of an aggregate for which the laws of Mariotte-Boyle and Gay-Lussac, long considered simple, are only the destruction of the action of individual molecules. Starting from these now well-known facts, M. Poincaré showed how the same methods and ideas apply to theories now being evolved concerning the interaction of matter and ether. His speech will no doubt be read and studied for a long time to come, and will remain one of the most perfect expressions of the state of mind of the masters of modern science.

To the organisers of the Congress, Lord Kelvin's promise of a personal contribution of work had been a powerful and valued encouragement. But what they hardly dared hope for was to see him, after the fatigues of a voyage, take a very active part in the Congress, and to see him hold spell-bound by the charm of his discourse a respectfully attentive audience bent upon seizing every thought of the great physicist. M. Poincaré's speech gave him an occasion for a brilliant improvisation on the constitution of the ether; and he also dealt with the subject in a paper on the waves produced in an elastic solid by the motion of a body acting upon it by attraction and repulsion. But it was not only in that speech that the illustrious honorary president of the Congress showed the interest he felt in the assembly. Presiding every day at sectional meetings, he clothed both reports and debates with a very special authority.

To facilitate work, the Congress had been divided beforehand into seven sections, the work of which I propose briefly to review.

In the measurement section, presided over by M. Benoit, the chief work was that of determining the actual state of metrology properly so called. After a very complete recapitulation, by the president, of the history of standards and methods employed in the measurement of length and the progress so far made, detailed attention was devoted to the complete metrological definition of standards and their legal definition; the legal status of the electrical units; and some improvements which might conveniently be made in a number of insufficient definitions, or definitions referring to conceptions recently introduced into science, such as the different abscissæ of the spectrum, &c. Some resolutions were passed, such as that recommending the adoption of the mechanical C.G.S. units (erg and joule) for the expression of calorimetric quantities, comprising, naturally, the solar constant, to be reduced by the meteorologists to the calorie per minute per sq. cm. Also that in the expression of elastic constants, the C.G.S. unit of pressure, the *barie*, be adopted, of which the multiple by $10^6$, the *megabarie*, is sufficiently represented by the pressure exercised by a column of mercury 75 cm. long at 0° and under normal gravity. The Congress further supported the sectional resolution that national laboratories be created in countries which do not as yet possess any.

The interferential methods of measurement brought out an excellent paper by M. Macé de Lépinay; there were also four contributions relating to thermometry of precision (Chappuis), pyrometry (Barus), the mechanical equivalent of heat (Ames), and a special study of the variation of the specific heat of water (Griffiths). All these showed that great progress has been made in these various departments. Thus at present the divergencies among the various gas thermometers are known over a long interval, and it is also known that though the hydrogen and nitrogen thermometers, for instance, may still differ between 0° and 100°, their divergence at the higher temperatures is insignificant if care is taken to slightly correct the mean coefficient of expansion between 0° and 100°. The difficulty of employing hydrogen at high temperatures lends a great importance to this provision. Pyrometry also is rapidly advancing, and as regards the mechanical equivalent, the great divergences which existed a few years ago have disappeared owing to a more complete correction of thermometric values and a better knowledge of electric standards.

Some very fine work has also been done in connection with gravitation. The measurement of the Newtonian constant, admirably expounded by Mr. Boys, whose special work in this department is now classical, and the announcement of anomalies of gravitation by Messrs. Bourgeois and Eötvös, gave rise to very interesting discussions. A few years ago these anomalies were placed beyond a doubt, and it is already possible to study the details with the aid of apparatus which, like that of M. Eötvös or that of Messrs. Threlfall and Pollock, indicates the most minute details, whereas the pendulum formerly employed only gave the more considerable anomalies. The Congress expressed a hope that the study of these anomalies will be pursued by the new methods, not only for the sake of knowing the gravitational acceleration in every place, but also for the better knowledge of the constitution of the globe.

Finally, M. Leduc presented to the section a report on the electro-chemical equivalent of silver, and M. Gouy another on the standard of E.M.F. It appears from the latter that the cadmium standard is preferable to every other.

The measurement of the velocity of sound, dealt with by M. Violle, forms in a manner the transition between the section of measurement and that of mechanical and molecular physics. In the latter, presided over by M. Violle, after a very complete treatise by M. Amagat on the whole of his work, and an admirable paper by M. van der Waals on the statics of mixed fluids, M. Mathias showed, in a paper well provided with references, how the critical point may be determined by various methods. Specialising further, Prince Galitzine dealt with the refractive index, and, finally, M. Battelli exhibited the relations between the statics of fluids and their calorimetry. Except as regards mixtures, the ideas on these various subjects are well fixed nowadays, and new light can only come from the experimental side. Mixtures are less known, and the paper in which the celebrated Amsterdam physicist condensed our actual knowledge of this question will no doubt powerfully contribute to make them known. Having created the idea of continuity between the liquid and the gaseous states, he has had the satisfaction of seeing it become classical. But it is in another direction that this evolution advances nowadays. Does this continuity also exist between the liquid and the solid state? The diffusion of solids, their flow under pressure, the constitution of alloys, so well studied, notably by M. Spring and Sir W. Roberts-Austen, might lead to that belief, especially since M. Schwedoff has proved the rigidity of liquids. M. Tammann raises some doubts concerning this idea, and recommends a careful distinction between the amorphous and the crystalline states. In any case, the presence at the Congress of the eminent physicists mentioned, with the exception of M. Tammann, who was represented by M. Weinberg, contributed greatly to the interest of the subject and to its future progress.

The study of the permanent or temporary deformations of solids naturally furnishes interesting data. A work by M. Mesnager, and another by the author of the present article, were devoted to these two questions. It is interesting to note that the last experimental researches are all in favour of the chemical theory of temporary deformations.

---

[1] These reports presented to the Congress have been translated into French. They were printed for purposes of discussion, and will be shortly published in three volumes.

M. Voigt has devoted a great amount of indefatigable activity to the study of the elasticity of crystals. His summary of this question was a great boon to the second section. It was a considerable piece of work, in which, naturally, the mathematical formula was predominant. This work will serve as a base for all those interested in the elasticity and the piezo-electricity of crystals, as well as in questions of symmetry.

M. van 't Hoff was not present at the Congress, but he showed his interest by sending a work on the formation of crystals in a mother-liquor containing a mixture of salts. In this case questions of equilibrium play an important part, the form of the crystals depending, not only upon the solubility of each salt in the mixture, but also upon the quantity of each.

It was very interesting to learn the ideas arrived at by M. van der Mensbrugghe, after a long career devoted to the study of capillarity. The report presented by Joseph Plateau's son-in-law constitutes a precious document on capillarity, a subject which has been somewhat eclipsed by other subjects, but which has formed the object of investigation of the greatest spirits, and continues to do so.

We must be short, and can only mention the report by M. Brillouin on gaseous diffusion, by M. Perrin on osmosis, and by M. Bjerknes on hydrodynamical actions at a distance. The latter derives its interest more especially from the fact that a hydrodynamical model may be constructed which possesses all the characteristics of a world subjected to actions at a distance.

The third section, presided over by M. Lippmann, dealt with optics. The recent researches on the laws of radiation naturally formed part of its programme, opened by those inseparable reports, on the theoretical laws of radiation, by M. W. Wien; on the radiation of solids, by M. Lummer; and on gaseous radiation, by M. Pringsheim. The practical realisation of the black body, the verification of Stefan's law for a large range of temperature, and certain simple relations between the temperature and the position of the maximum in the spectrum, are the salient facts which the experimental work of recent years has brought out. For gases, a doubtful point is the validity of Kirchhoff's law, but according to M. Pringsheim that does no seem to be in any danger if only the purely thermal radiati is considered.

Recently, the spectrum has been greatly extended in the infra-red. M. Rubens, to whom the greatest progress in this direction is due, had undertaken to give a summary of this question, showing how the dispersion formulæ agreed with experiment, and demonstrating experimentally the connection between long light waves and electrical waves. This work again called forth a discussion on the formulæ and theories of dispersion opened by M. Carvallo.

The kinematics of the spectrum has also made great progress since Balmer showed for the first time that the hydrogen rays are represented by a very simple formula. The researches of Kayser and Runge and other physicists, Rydberg among them, have shown that the distribution of the spectrum lines is governed by laws, some of which are clearly established, while others are as yet unknown. Of all this work, M. Rydberg gave an excellent summary.

The velocity of light has, as we know, given rise to metrological work of the first rank, and of extreme difficulty. It fell to the distinguished president of the Congress, M. Cornu, to give a review of this subject, and during the remarkable speech which he delivered at the École Polytechnique, the physicists from all parts had the privilege of seeing the original apparatus of Fizeau and of Foucault, who were the first to give an approximate value of that velocity by measurements confined to the earth.

It is this characteristic velocity which for Maxwell was the touchstone of the theory involving the identity of luminous and electrical oscillations. As the instruments become more perfect, and the sources of error disappear, this identity is more and more emphasised. It was very interesting to co-ordinate the numbers furnished by light proper with those furnished by the comparison of units and the direct measurement of the velocity of electric waves. M. Abraham undertook the first part of this work, and MM. Blondlot and Gutton the second. This brings us to the electrical section, presided over by M. Potier, and in his absence by M. Bouty. The line of demarcation, however, is becoming more and more difficult to draw. The extremely interesting work of M. Lebedef on the pressure produced by radiations, has its origin in the great work of Maxwell; but it might also arise from pure thermodynamics, as shown by Bartoli and Boltzmann. As regards Hertzian waves, treated in a masterly manner by M. Righi, they approach so closely to the work of M. Rubens, that the small interval which still separates them is probably the only reason—and a very artificial one—for keeping them separate at all. In a supplementary note, M. Branly gave an account of some of his own researches on coherers. The reports just mentioned furnished the experimental side of an idea, the theoretical aspect of which was treated of in a paper by Prof. Poynting on the propagation of electrical energy.

We encounter another group of questions in the gaseous dielectrics, studied by M. Bouty, as well as electrolysis and ionisation, which have made such vast progress during the last decade, and which were dealt with by M. Arrhenius, one of the promoters of the new ideas, in a paper which will remain a model of clearness. Finally, we have M. Christiansen's theories of contact electricity, M. L. Poincaré's theories of the electric cell, and the exposition of Nernst's ideas, which had not been contemplated in the programme of the Congress, but which enabled their founder to give to the meeting a review admirably completing this group of questions.

The presentation of present ideas on magnetism had been excellently prepared by two fundamental reports, one, by M. du Bois, on the general magnetic properties of bodies, and another, by M. Warburg, on hysteresis, which he was the first to observe, and which, in the hands of Ewing, Hopkinson and others, attained such great importance. Two particular aspects of magnetism, viz. magneto-striction and the E.M.F. of magnetisation, which could not form part of the general reports, were treated separately by M. Nagaoka and M. Hurmuzescu.

Although the applications of electricity are almost entirely beyond the subject-matter of the Congress, there are some which are connected so closely with general physics that it seemed very desirable to have them dealt with. This was done by M. von Lang, whose work on the electric arc is well known, while M. Potier gave an exhaustive paper on the theory of polyphase currents, and M. Blondel the description of apparatus for tracing the curves of rapidly varying currents.

In a few years' time the work of the fifth section—ionisation and magneto-optics, presided over by M. Becquerel—will no doubt fall naturally into one of the preceding sections. But at the present moment they are still so undefined, they open up such new horizons, that it appeared well to collect them in a special section. The idea proved very fruitful, for the section was largely attended, and the discussions at it proved very fascinating.

M. Lorentz had prepared an admirable report on magneto-optics, with special reference to the Zeeman phenomenon. He expounded both his own ideas and those of M. Voigt. The presence of the latter gave the section the privilege of an exposition at first hand of his latest ideas.

The absence of Prof. J. J. Thomson could not but be severely felt. But the work which he had sent in, concerning the ratio of the electric charges to the masses carrying them, was read amid great interest after the general exposition made by M. Villard of the state of our knowledge of kathode rays.

The phenomena of actino-electricity, somewhat forgotten now, though much studied ten years ago, gave rise to a report by MM. Bichat and Swyngedauw. Perhaps increased attention will be devoted to them now that the researches of M. Becquerel and those of M. and Mme. Curie have proved so fertile in the examination of new bodies.

The speeches in which first M. Becquerel and then M. Curie expounded the disconcerting properties of uranium, polonium and radium rays, were for many a revelation. These extraordinary bodies, discovered by their radio-active properties, which were first announced by M. Becquerel, and then followed up with such startling success by M. and Mme. Curie, were known to the majority of those present, but only a few had seen those few decigrammes of material extracted from several tons of the mineral richest in it, pitchblende, and certainly the effects produced surprised by their intensity those who saw them for the first time.

Several hundred persons at a time could see this light, which appears everlasting, radiated perpetually by radium, the clear patch which it produces even across a sheet of metal on a screen of barium platino-cyanide, the instantaneous discharge of an electrified body brought near to the substance, and the sparks passing when radium is brought within a few centimetres of the spark gap. The magnetic deflection of the rays could, of course, not be made evident to such a large audience. But the original negatives could be projected, and they showed the curvilinear propagation of the rays in a magnetic field.

The new bodies constantly project matter endowed with a great velocity. Neighbouring bodies are impregnated with it, and become radio-active in turn. These particles attach themselves, not only to objects, but to persons as well, so that M. Curie will be condemned for some time to abandon every kind of electrostatic research. No electrometer remains charged in his neighbourhood, and it is certain that if radium had only been as plentiful as gold, static electricity would never have been discovered.

In the same domain, important generalisations have been made, such as the theory of dispersion in metals, founded by M. Drude upon the electron theory, of which the author gave an account to the section.

The sixth section, under the presidency of M. Mascart, occupied itself with cosmical physics. Terrestrial magnetism should undoubtedly have formed part of the work of this section, but the Meteorological Congress which will shortly meet intends to make that the principal object of its studies, and it was evidently necessary to leave it aside.

Yet the work of this section was very fruitful. Here, naturally, observation still holds a predominant place, as in the work of the Swiss physicists, with M. Hagenbach at their head, on glaciers; and the detailed study of oscillations of lakes by MM. Sarasin and Forel, who brought their results before the Congress.

In the department of atmospheric electricity, a very good account was given by M. F. Exner, and Mr. Paulsen gave an account of the Danish expedition to Iceland for the study of the aurora. The evaluation of the solar constant by M. Crova, according to recent researches, and a very ingenious theory of suns-pots established by M. Birkeland after troublesome calculations, were heard with much interest. Finally, M. C. Dufour showed how, without the help of any laboratory apparatus, the approximate brightness of the stars could be determined.

It had seemed useful to collect in a seventh section some works relating to biology. In the absence of M. d'Arsonval, this section, presided over by M. Charpentier, did a great deal of good work, and justified the idea of the organisers of the Congress. The application of physical and mathematical methods to the transmission of energy in organisms, to which M. Broca has devoted attention for a considerable time, and the curious retina phenomena studied by M. Charpentier, gave this section a vast field of discussion. Finally, the new theory of accommodation established by M. Tscherning received the sanction of a very largely attended meeting, while M. Hénocque spoke of the spectroscopic methods used in biology.

The proceedings of the Congress were not confined to sectional work and general meetings. A visit to the laboratories of the Sorbonne and the École Polytechnique showed many experiments in progress, installed by the professors of these establishments or their provincial and foreign colleagues. These could only be properly appreciated by observing them closely and in small groups.

Shall I speak of the reception in the Jardin de l'Elysée, whither the President of the Republic invited several Congresses to witness a theatrical performance? Or of the charming *soirée* for which Prince Roland Bonaparte had placed at the disposal of the organisers his vast and magnificent library for a number of interesting experiments? This *soirée*, which will leave in the minds of all who were present the most agreeable memories, would itself deserve a lengthy description. But I cannot conclude this already lengthy article without saying how much the French physicists have been touched by the sympathetic action of the foreign secretaries of the Congress, who deposited a magnificent crown on the modest tomb of the great Fresnel, of which the Société Française de Physique has constituted itself the guardian. A moving speech by M. Warburg, and a warm expression of thanks by M. Cornu, president both of the Congress and of the Society, referring in a few words to the life of that great physicist, ended this first Congress, where so many new thoughts have been born, and so many friendships made or consolidated.

CH. ED. GUILLAUME.

## *ORIENTATION OF THE FIELD OF VIEW OF THE SIDEROSTAT AND COELOSTAT.*

OBSERVERS who have practical acquaintance with the siderostat and heliostat are familiar with the fact that while the reflected image of a star may be kept stationary, the images of surrounding stars have a rotation around it; while if the sun is the object viewed in the mirror, the image will rotate about the axial ray. It is on account of this rotation of the field that neither the siderostat nor the heliostat can be used with a fixed telescope for celestial photography, except for objects which can be photographed with short exposures.

Certain unexpected peculiarities of this motion have recently led Prof. Cornu to investigate the general laws governing the rotation of the field in both instruments (*Comptes rendus*, vol. cxxx. No. 9, 1900; *Bulletin Astronomique*, February 1900). Some of the results at which he has arrived are of great interest, and we believe attention has not been previously drawn to them, although they could have doubtless been derived from Orbinsky's formula for the orientation of the field ("Die totale Sonnenfinsternisse am 9 Aug. 1896"), or from other formulæ which have been employed by observers as occasion required.

Prof. Cornu first discusses the general question of the orientation of the field, irrespective of the mechanical means of retaining the reflected image in a fixed position. In Fig. 1, NESW represents the horizon, Z the zenith, P the pole, PD the hour circle of the star D, and D′ the point of the horizon towards which the rays are reflected. PN is equal to the latitude of the place, = L; PD is the polar distance of the star, $= \delta$; SPD is the hour angle of the star, $= h$. For the purposes of calculation the point D′ is defined by its polar distance PD′ $= \rho$, and by the angle SPD′ $= \omega$ which the plane PD′ makes with the meridian; $\rho$ and $\omega$ can be determined in terms of the azimuth of D′ (= SD′ $= \alpha$, reckoned positive towards the west) and the latitude, by solving the right-angled triangle PSD′, in which PS $= 180° - \mathrm{L}$; thus

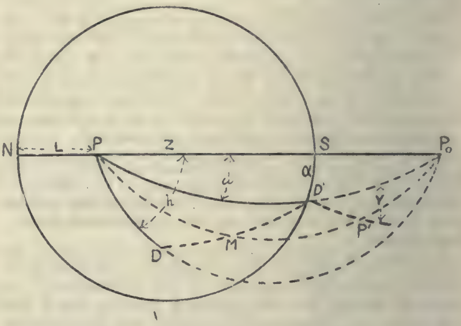

FIG. 1.—Orientation of field of siderostat.

$$\cos \rho = \cos \alpha \cos \mathrm{L}\,; \ \tan \omega = \frac{\tan \alpha}{\sin \mathrm{L}}.$$

The normal to the mirror must always bisect the arc DD′ of a great circle, at M, so that the position of the reflected ray from any part of the sphere can be easily determined. Thus the image of P is at P′ in the continuation of the hour circle PM, MP′ being equal to PM. To determine the orientation of the field, it is most convenient to ascertain the direction, after reflection, of the point P, since it is a fixed point on the sphere. Taking the plane of $\mathrm{PD'P_0}$ as the reference plane, and its trace on the sphere as a fixed direction, the orientation of the reflected pole is conveniently defined by the angle $\mathrm{P_0D'P'} = \mathrm{Y}$, which can be readily calculated, as also D′P′, the distance of the reflected pole from the centre of the field.

Applying this in the first place to the siderostat, where the reflected rays are south or nearly so, and the angle $\alpha$ consequently small, Prof. Cornu obtains the following results:—

(1) The reflected image of the pole describes a circle round the centre of the field, with a radius equal to the polar distance of the star observed.

(2) Since the angle Y is equal to the supplement of the angles at the base of the triangle PDD′, P being the apex, the orientation of the reflected pole (that is, the direction of the north point of the field) is given by the equation

$$\tan \tfrac{1}{2} \mathrm{Y} = \frac{\cos \frac{1}{2}(\rho+\delta)}{\cos \frac{1}{2}(\rho-\delta)} \tan \tfrac{1}{2}(h-\omega)^{1}$$

The law of rotation readily follows. The interval from the passage of the star over the hour circle PD′ being expressed by $t$, with a day as the unit of time, $h - \omega = 2\pi t$, and the equation becomes

$$\tan \tfrac{1}{2} \mathrm{Y} = \mathrm{K} \tan \tfrac{1}{2}\, 2\pi t.$$

$$\text{where } \mathrm{K} = \frac{\cos \frac{1}{2}(\rho+\delta)}{\cos \frac{1}{2}(\rho-\delta)}$$

Hence :—(*a*) The rotation of the field has the same period as the diurnal motion.

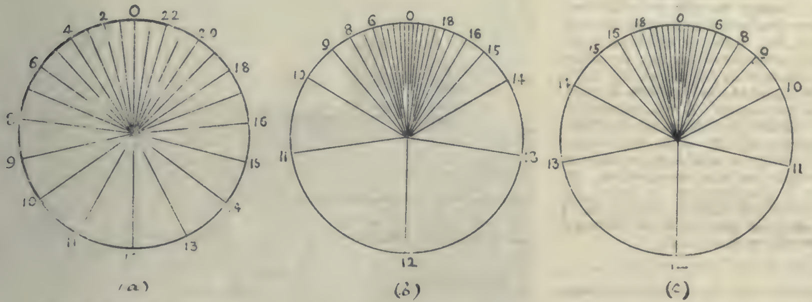
(*b*) The motion is continuous and in the same direction, direct or inverse according to the sign of K.

(*c*) The plane of reference is a plane of symmetry, since the angle Y has equal values of contrary sign at equidistant intervals of time from passage across the reference plane.

Prof. Cornu illustrates the rotation by a diagram similar to those in Fig. 2.

(3) The angular velocity of rotation at the epoch $t$ is given by

$$\frac{d\mathrm{Y}}{dt} = 2\pi \frac{\mathrm{K}}{\cos^2 \pi t + \mathrm{K}^2 \sin^2 \pi t}.$$



(*a*) Sun at winter solstice, London.

(*b*) Sun at summer solstice, London.

(*c*) Star through zenith, London.

FIG. 2.—Illustrating rotation of field of siderostat.

The denominator is always positive, so that the velocity has always the same sign as K; its value varies from $2\pi\mathrm{K}$ (when $t = 0$) to $\frac{2\pi}{\mathrm{K}}$ (when $t = \frac{1}{2}$), and is equal to the diurnal motion when the conditions make the denominator equal to K. The velocity varies so slowly for small values of $t$, that it may be sufficient to regard it as constant and equal to $2\pi\mathrm{K}$. Since the northern meridian passage cannot be observed with the siderostat, the value $\frac{2\pi}{\mathrm{K}}$ is not observable.

(4) The apparent motion of the field, as seen in the mirror, will evidently be in the same direction as the apparent motion of D′P′ seen from outside the sphere, and it will not be reversed by an astronomical telescope. When the polar distance of the star observed is less than the supplement of the polar distance of the reflected ray, the apparent direction of rotation of the field of a siderostat is clockwise; it is in the contrary direction if the polar distance of the star is greater than this supplement.

(5) When $\cos\frac{1}{2}(\rho+\delta) = 0$, we have $\mathrm{K} = 0$, and $\mathrm{Y} = 0$ for all values of $t$. Hence there is no rotation of the field when the polar distance of the star observed is equal to the supplement of the polar distance of the direction of the reflected ray.

In this case, $\rho + \delta = 180°$, and $\mathrm{PM} = 90°$, so that the mirror is parallel to the earth's axis, and the instrument thus behaves like a cœlostat.

(6) When the reflected ray is in a horizontal and southerly direction, as is usually the case, $\omega = 0$, and $\rho = \pi - \mathrm{L}$, so that the formula for orientation becomes

$$\tan \tfrac{1}{2} \mathrm{Y} = \mathrm{K} \tan \tfrac{1}{2} h$$

where

$$\mathrm{K} = \frac{\sin \frac{1}{2}(\mathrm{L}-\delta)}{\sin \frac{1}{2}(\mathrm{L}+\delta)}.$$

It readily follows that there is no rotation of the field in this case when the polar distance of the star observed is equal to the latitude of the place of observation; the rotation is clockwise if the polar distance be less than the latitude, and contrary if greater. Fig. 2 illustrates the varying conditions of rotation in the latitude of London (*a*) for the position of the sun at the winter solstice, (*b*) for the position of the sun at the summer solstice, and (*c*) for a star which passes through the zenith. In each case the numbers are placed to represent the position angles of the north point of the field at corresponding hour angles.

In the case of the heliostat, where the rays are reflected in a northerly direction, a similar method of computation is adopted by Prof. Cornu; but as the instrument is so little used in work of precision, it is unnecessary to give the details. The important result is that the field of view under ordinary conditions has an angular velocity of rotation greater than that of the diurnal motion.

A knowledge of the orientation of the field as reflected by a mirror is so frequently required that it may be useful to refer briefly to other ways of treating the problem.

Orbinsky proceeds much in the same manner as Prof. Cornu, but considers the more general case in which the reflected rays are neither in the meridian nor horizontal. The position of the normal is midway between the direction of the star and that of the reflected ray, on a great circle, so that the direction of the reflected ray from any other point of the celestial sphere can at once be determined.

In this way the position of the zenith point of the field (vertex) is derived with respect to the vertical circle in the plane of the reflected ray. A calculation of the angle between the vertex and the north point is then all that is required to give the direction of the north point of the field with respect to a vertical line through it.

Another method of representing the orientation was adopted by Mr. Shackleton in connection with the eclipse of 1896. This can be applied to a reflection in any direction, but it will suffice to indicate its application to a siderostat with the reflected ray in the meridian. Using Prof. Cornu's notation so far as possible, in Fig. 3 NESW is the horizon, NPS the meridian, P the pole, D the star, M the mirror, MS the direction of the reflected ray from D, and SDN the trace of the plane of reflection. Representing the direct field by *anb*, *n* is the north point. The field of the mirror appears behind the mirror as *a′n′b′*, *a′b′* remaining in the plane of reflection, and *b′*N*n′* being equal to *b*D*n*. Since N*v* is a vertical line through the field of the mirror, and *v*N*a′* = DSP, it is evident that *v*N*n′* = 180° − (PSD + PDS).

---

[1] This gives the angle reckoned from the direction D′P. To obtain the inclination to a vertical line passing through the mirror, it would be necessary to calculate the angle PD′Z.

$vNn'$ thus corresponds with the angle Y in Prof. Cornu's formula, and its value is derived by precisely the same formula.

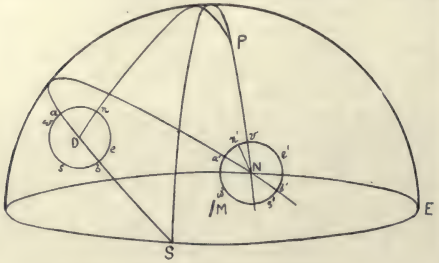


FIG. 3.—Orientation of field of siderostat.

The orientation of the field of a cœlostat is very readily derived. In this instrument the mirror turns on a polar axis in its own plane, so that the normal is always on the equator, and the polar distance of the reflected ray is always equal to the supplement of the polar distance of the star. Thus, in Fig. 4, PD' is the supplement of PD. The reflection of the hour circle through the star, PD, will coincide in direction with that through the reflected ray, PD', so that $n$ will become $n'$, and it only remains to determine the angle PD'Z to ascertain the position of the north point with regard to a vertical line through the field of the mirror. If we suppose the rays to be reflected in a horizontal direction, in the triangle PZD, PZ = the co-latitude, ZD' = 90° and PD' = 180° − PD, so that the required angle can be at once derived. In this case it is convenient to know the azimuth of the reflected ray, that is, PZD'; and the simplest solution is to calculate this angle first by the formula

$$\cos \text{PZD}' = \cos (180° - \text{PD}) \sec \text{L}.$$

The required angle is then derived from the formula

$$\sin \text{PD}'\text{Z} = \sin \text{PZD}' \cos \text{L} \operatorname{cosec} (180° - \text{PD}).$$

The position of the north point having been determined, the remaining points can at once be placed, noting that the east and west points are reversed as compared with the direct view in the sky.

It is important to note that although there is no rotation of the field so long as the telescope remains in one position, the whole field is turned when the telescope is set in a different direction. Thus, if the telescope is directed west for observations of the morning sun, the orientation of the field will be different when the telescope is pointed in an easterly direction for observations of the sun in the afternoon; in the former case the north point lies to the right of the vertical, and in the latter case to the left.

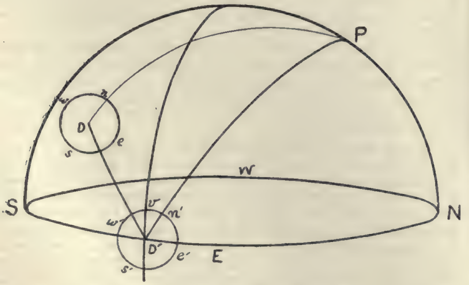

FIG. 4.—Orientation of field of cœlostat.

Other investigations relating to the cœlostat, including the determination of the best position for the telescope under given conditions, have been made by Prof. H. H. Turner (*Monthly Notices R.A.S.*, vol. lvi. p. 408).

As the cœlostat has not yet come into very general use, it may be of interest to add a few remarks as to the arrangements which have been made by Sir Norman Lockyer at the Solar Physics Observatory for utilising this instrument in a permanent observatory (Fig. 5). On account of the varying declinations of the heavenly bodies, the position of the observing telescope must admit of corresponding changes, either in inclination or azimuth, or both. When special instruments, such as the spectro-heliograph, are to be used with the cœlostat, as at the Solar Physics Observatory, motion in azimuth is the only motion permissible, and this is provided for by fixing the receiving instrument on a platform which runs on circular rails, with the cœlostat at the centre. The platform carrying the telescope or spectroscope is covered with a travelling hut, the roof of which is inclined so as not to obstruct the mirror. The cœlostat itself is provided with a hut, which is removed to the north when the instrument is in use; this is shown to the left in the illustration.

A. FOWLER.

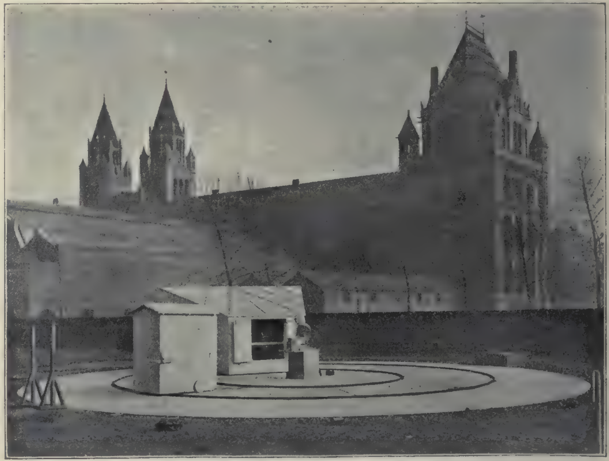

FIG. 5.—The cœlostat of the Solar Physics Observatory.

## THE ANNIVERSARY MEETING OF THE REALE ACCADEMIA DEI LINCEI.

A MELANCHOLY interest attaches to the anniversary meeting of that ancient scientific society, the Reale Accademia dei Lincei, held in June, from the fact that the society was then mourning the loss of its distinguished president, Prof. Beltrami, and has since been plunged into deeper mourning by the untimely and unexpected loss of its patron, King Humbert, who with Queen Margherita had for many years taken part in these yearly meetings. It is, moreover, largely due to the munificence of the late King of Italy that the society is enabled to further the advancement of science by the award of prizes for theses dealing with some subject of scientific research.

From the presidential report of Prof. Mesadaglia, we learn that the society's losses have included, besides Beltrami, the names of Capasso, De Simoni, Ferrara, Nestore and Tommasi-Crudeli among the ordinary members, and, of foreign members, Bertrand, Bunsen, Janet and Liais. The *Atti*, or "Proceedings" contain for the year 147 papers, in addition to which several longer papers are being printed in the *Memorie* or "Transactions," and the corresponding societies with which an exchange of publications is made now number not less than 500. Under the title of *Notizie degli Scavi*, the society brings out accounts of archæological discoveries in Italy, the material for which is furnished monthly by the Minister of Public Instruction. Of recent publications, we note the issue of three volumes of the "Codex Atlanticus" of Leonardo da Vinci, a magnificent work, in the cost of publishing which the late King gave material assistance; also the "Forma Urbis Romæ" of Signor Lanciani, consisting of a large scale archæological map of Rome.

For the Royal prize of 1000 francs for normal and pathological physiology six candidates entered, and a large number of essays of considerable merit were submitted by them. The prize has been adjudged to Prof. Giulio Fano, of Florence, for sixteen papers, dealing, amongst other subjects, with the physiology of the embryonic heart, the doctrine of experimental psychology, the organ of hearing, the graphic registration of respiratory chimism and reflex movements, the latter being a continuation of previous researches on the organs of *Emys Europea*. Of the six candidates for the Royal prize for geology and mineralogy, two were considered worthy of the award, which was therefore divided equally between them. One of the successful candidates, Prof. De Lorenzo, chose geological subjects, and sent in about twenty essays, the most important of which dealt with the trias of the environs of Lagonegro, the mesozoic mountains of Lagonegro, geological observations on the Apennines of the southern Basilicate, and geological studies of the southern Apennines. Prof. Giorgio Spezia's work, on the other hand, was entirely mineralogical, dealing with the influences of temperature and pressure, respectively, on the chemical metamorphism of rocks and minerals. From a long and laborious series of experiments, many of them occupying five or six months, the author concluded that pressure has little or no effect, while the influence of temperature is considerable. The results have a special bearing on the theory of quartz formation. The Royal prize for advances in archæological science was adjudged to Dr. Paolo Orsi, of Roveredo, for his investigations of the antiquities of Eastern Sicily. Dr. Orsi has thrown quite a new light on the prehistoric development of the people known as the Siculi, from the neolithic epoch down to the period of expansion of the Greek colonies. A special prize for philosophy and moral science had been offered for an essay dealing with either the theory of consciousness or the foundations of practical philosophy. This prize has been divided equally between Prof. Bernardino Varisco and Prof. Francesco de Sarlo. The Minister of Public Instruction offered a sum of 3400 lire for two prizes in physical and chemical sciences, and a like sum for two prizes in philological sciences, the prizes being confined to teachers in secondary schools. The committee for the prizes in physical and chemical sciences have awarded two equal prizes—one to Prof. O. Marco Corbino, more especially for his work on light traversing metallic vapours in a magnetic field, and the other to be divided between Profs. Carlo Bonacini and Riccardo Malagoli, more especially for their joint papers on Röntgen rays. In philology, the prizes have been divided up into a number of minor awards, distributed between Signori Giuseppe Vandelli (whose work stood first), Antonio Belloni, Astorre Pellegrini, Giuseppe Rua, Giuseppe Lisio, Augusto Balsano, Giovanni Negri and Guglielmo Volpi.

At the conclusion of the awards a biographical commemoration of the late Prof. Beltrami was delivered by Prof. Luigi Cremona. In the number of the *Atti*, this is followed by a chronological list of Beltrami's scientific works, in compiling which use has been made of the previously published lists by Prof. Dini, and by Signori Pinti and Brambilla in the *Annali di Matematica* and the *Rendiconto* of the Naples Academy respectively.

The proceedings terminated with an address by Signor Giuseppe Colombo on the progress of electrotechnics in Italy. Signor Colombo briefly traced the gradual development of the theory of the electrical transmission of energy, from the discovery of Volta, through the various stages indicated by Pacinotti's invention of the first dynamo, Galileo Ferraris' principle of the rotating magnetic field, and a number of intermediate inventions, down to the principle of wireless telegraphy, to the development of which two Italians, Righi and Marconi, have so largely contributed. The absence of coal has long been a serious bar to the progress of Italy in commercial competition, but Signor Colombo proves by statistics that Nature has provided a source of energy more than sufficient to fill the deficiency, in the water-power with which the country has been well endowed, and it only needs the development of plant for the electrical transmission of power, aided, moreover, by the best means for minimising waste of energy, to raise Italy to a condition of commercial prosperity.

## UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE *Pall Mall Gazette* states that Miss Cruickshank has given to Aberdeen University, in memory of her brother, Dr. Alexander Cruickshank, the botanic garden at Chanoury, Old Aberdeen, extending to six acres, and capable of accommodating nearly six thousand specimens. Miss Cruickshank has devoted to its endowment the sum of 15,000*l*.

MR. GILBERT R. REDGRAVE, Senior Chief Inspector in the South Kensington branch of the Board of Education, has been appointed an Assistant Secretary for Technology. Announcement is made that in the ensuing autumn the Duke of Devonshire will appoint a departmental committee, on which the county councils and the City and Guilds of London Institute will be represented, to consider, *inter alia*, the co-ordination of the technological administration of the Board of Education with the technological work at present carried on by educational bodies other than that Board.

A GOOD idea of the scope and value of the work of the examinations department of the City and Guilds of London Institute can be obtained from the "Programme of Technological Examinations (1900–1901)," published by Messrs. Whittaker and Co. Examinations are held in seventy technological subjects, and also in manual training (wood-work and metal-work). For each examination a syllabus is given, and a useful list of works of references; and the questions and practical exercises set at the recent examinations are all reprinted. Several of the syllabuses have been revised, notably those of photography, pottery and porcelain, silk throwing and spinning, and silk weaving, electric lighting, watch and clock making, typography, lithography, carpentry and joinery.

THE Redruth School of Mines, of which the syllabus for 1900–1901 is before us, offers exceptional facilities for studying the principles of mining in the Cornish mining district. One wing of the school building is occupied by a large mineral gallery, erected to the memory of the late Dr. Robert Hunt, F.R.S. The museum, which contains a valuable collection of mineral specimens, and is the property of the Mining Association and Institute of Cornwall, is at all times accessible to students of the school. The mining course consists of practical underground work, including the timbering of shafts and levels, and of lectures on geology, the principles of mining, the raising and mechanical preparation of ores, and of practical work in gold panning and vanning. Students, in addition, are taught the methods of prospecting for minerals in all possible positions, and are trained to detect favourable indications on the surface. There is thus a reasonable combination of science with practice in subjects essential to the training of mining engineers.

WHAT school gardens are to children, allotments are to adults in agricultural districts, and both provide valuable means of experiment. The Report of the Technical Instruction Committee of the Oxfordshire County Council shows that this is well recognised is several parts of the county. For instance, at the Chipping Norton Agricultural Class there were fifty-four students of an average age of thirty-eight. They were factory hands, labourers, mechanics and small tradesmen, who all cultivated allotments, and were thus able to put principles to a practical test, and determine the causes thus affecting growth. At Reading College, which is connected with the Oxfordshire Committee, various insects and plants were received from different parts of the county for identification, and advice was given in many localities. Field experiments were made on sainfoin and lucerne, rotation, "finger and toe," mangel, and different manures for barley. Charlock spraying was investigated at three farms, and other experimental work had been done under the auspices of the College and the Technical Education Committee.

## *SCIENTIFIC SERIAL.*

*American Journal of Science*, August.—Rowland's new method for measuring electric absorption and losses of energy due to hysteresis and Foucault currents, and on the detection of short curcuits in coils, by L. M. Potts. Rowland's method, in which the condenser is placed in one arm of a Wheatstone bridge, together with the fixed coils of an electrodynamometer, while the movable coil is mounted in the cross connection, is practically useful. The electric absorption always acts as a resistance in series with a capacity. The resistance is independent of the current, but the temperature has a decided effect on both.—Some new Jurassic vertebrates, by W. C. Knight. The author describes two new species, called *Plesiosaurus shirleyensis* and *Cimoliosaurus laramiensis* respectively. They are in the collection of the University of Wyoming.—Carnotite and associated vanadiferous minerals in Western Colorado, by W. F. Hillebrand and F. Leslie Ransome. Carnotite is probably a mixture of minerals of which analysis fails to reveal the exact nature. Instead of being the pure uranyl-potassium vanadate, it is to a large extent made up of calcium and barium compounds. Near Placerville, Colorado, certain sandstones show a green colouring and cementing material which contains nearly 13 per cent. of $V_2O_3$. It is intended to work this sandstone for vanadium.—Restoration of Stylonurus Lacoanus, a giant arthropod from the Upper Devonian of the United States, by C. E. Beecher. The arthropod described takes equal rank with the Giant Spider Crab of Japan and the great "Seraphim" (*Pterygotus anglicus*). The animal has a length of nearly 5 feet, and with the legs extended it would measure about 8 feet.—Iodometric estimation of arsenic acid, by F. A. Gooch and Julia C. Morris.—Further notes on pre-glacial drainage in Michigan, by E. H. Mudge. The author discusses the present and former levels in the vicinity of the village of Saranac.

## *SOCIETIES AND ACADEMIES.*

### PARIS.

**Academy of Sciences,** August 20.—M. Maurice Lévy in the chair.—New observations on the high valley of Dordogne, by M. A. Michel-Lévy. Owing to the cuttings recently made for the railway between Queuille and Mont-Dore, some new facts on the geology of this valley have been discovered. On the left flank of the valley the deposit of labradorite can be traced up to the Capucin. More to the south an outcrop of trachyte, rich in black mica and amphibole, can be followed up to near the ravines of Riveaugrand. The right flank of the Mont-Dore valley shows clearly the prolongation of the lower andesite of the Grand Cascade. A trachytic dyke has also been recently discovered by M. Paul Gautier in the first ravine west of Compissade, which is rich in granitic inclusions.—On the existence of *Ceratitis capitata*, var. *hispanica*, in the neighbourhood of Paris, by M. Alfred Giard. During the present spring a large proportion of the apricots at Courbevoie, near Paris, fell off the trees in a green state, and the remainder, although apparently exceptionally fine when ripe, where found to be honeycombed with larvæ. This larvæ were found, on development, to give rise to *Ceratitis capitata*, a species that has already been found to be very destructive to many kinds of fruit in the Azores, at Madeira, the Cape of Good Hope, Algeria and Malta. This is its first appearance near Paris, possibly owing to an exceptionally favourable spring. Means for combating this scourge are suggested, as it is of the first importance that it should not become acclimatised in Paris.—Observations on shooting stars made from August 11 to August 14 at the Observatory of Paris, by Mlle. D. Klumpke. About thirty meteors were observed during four nights, of which some came from Perseus and others from the polar region. The former were white, short and very rapid, the latter luminous and coloured.—Observations of the sun made at the Observatory of Lyons with the Brunner equatorial during the first quarter of 1900, by M. J. Guillaume. The results are given in three tables showing the number of spots, their distribution in latitude, and the distribution of faculæ in latitude.—On the composition of the air in a vertical section, and on the composition of the upper layers of the terrestrial atmosphere, by M. G. Hinrichs. By applying a formula of Laplace, the composition of the air is deduced at different levels. From these calculations, carbon dioxide would disappear at 30,000 metres, argon at 60,000 metres. At 100,000 metres the air would consist of oxygen 0·3, nitrogen 4·6 and hydrogen 95·1 per cent.—On the dielectric cohesion of gases, by M. Bouty. When a gas contained in an insulating vessel is placed in a constant electric field, there is a certain critical pressure above which the gas acts as a dielectric, and below which the discharge passes. The relation between this critical pressure ($p$) and the field ($y$ volts per centimetre) has been studied for three gases—hydrogen, air and carbon dioxide. For low pressures the relation found is $y = a + \frac{c^2}{p^2}$. For higher pressures the curve is practically coincident with the asymptote, $y = a + b(p + \pi)$.—On the extraction of oxygen from the air by solution at a low temperature, by M. Georges Claude. Various solvents for air have been tried at low temperatures in the hope of discovering a liquid in which the difference of solubility of the two gases would be very marked. The experiments, however, were unsuccessful, as it was found that at low temperatures the solubility of the nitrogen increased, so that starting with a mixture containing 65 per cent. of oxygen, after solution and boiling out, the amount of oxygen was practically unchanged, amounting in no case to more than 70 per cent.—On the pyrogallol-sulphonic acids, by M. Marcel Delage.—On the dextrins of saccharification, by M. P. Petit. The results obtained by the action of diastase upon starch were very divergent, depending upon the age of the diastase and the conditions under which it had been preserved.—On the use of sodium peroxide for making wholesome wells containing carbonic acid, by M. E. Derennes. The use of milk of lime for the absorption of dangerous amounts of carbonic acid contained at the bottom of a well has the disadvantage that the residual gas may consist almost entirely of nitrogen. The substitution of sodium peroxide for lime would ensure as much oxygen being given off as carbon dioxide absorbed.

THURSDAY, SEPTEMBER 6, 1900.

## *A NEW DEPARTURE IN THE TEACHING OF ZOOLOGY.*

*Introduction to Zoology: a Guide to the Study of Animals, for the use of Secondary Schools.* By C. B. Davenport, Ph.D., and Gertrude C. Davenport, B.S. Pp. xii + 412. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1900.)

THE senior author of this book is well known in zoological circles for his two-volume work on "Experimental Morphology"—one of the most novel and ambitious of modern text-books; and his wife, whose aid he acknowledged in its preface, now appears as joint author of the present equally ambitious production, which has for its object nothing short of a revolution of the methods of zoological teaching in vogue in the secondary schools of the United States. The key to the plan of the work and nature of its contents lies in the prefatory pronouncement that the "vast majority of secondary students are not to be zoologists, but rather men of affairs," and that "what the ordinary citizen needs" zoologically is (not a course in comparative anatomy but) "an acquaintance with the commonest animals"—a knowledge of "where else over the world the common animals of his State are to be found, and of how animals affect man," and that to know these matters is for him "more important than to know the location of the pedal ganglion of the snail." There can be little doubt that in this resolve the authors are in agreement with a large section of active teachers, but it must not be forgotten that the didactic system of laboratory instruction in vogue, against which they are in the long run entering a protest, has in its development become modified beyond the conceptions and intentions of its founders, and that as originally planned it did not ignore non-anatomical considerations to the extent their attitude implies. In their forcible recognition of the later tendency towards so doing, however, and their bold attempt to overcome it, they have performed a useful task, but experience can alone decide upon the wisdom of the remedy they propose.

Their book is of 336 pages, excluding appendices, and is divided into twenty-one chapters. The first four chapters deal with the Insecta, and then follow one each devoted respectively to the Myriapoda and Spiders, two each to Crustacea, Worms and Molluscs, one each to the Echinodermata, Cœlenterata and the Protozoa, and then a series on the Vertebrates taken in ascending order, the whole closing with a novel chapter on the frog's egg as a study in development. The plan adopted in each chapter is much as follows:—Opening with a concise statement of the systematic position and relationships of an order or other great group of animals conveniently selected (with a definition of its name usually in a footnote), there follows a very brief description of the habitus, and if so be the food and other special topics of interest, of one or more of its familiar species. There is then given a short descriptive account of its more familiar allies, and it may be of its development; and the whole chapter is brought to a close by an appendix, in the form of a key to the families of the order to which the type chosen belongs, or to the orders of the class or other great divisions of the group under consideration, while in places an accompanying key to the identification of members of allied subfamilies may be added or incorporated. The plainest and most concise terms are adopted, and there is a tolerably free use of illustration, preference being given to photographs of entire animals, often with their natural surroundings, in many cases with marked success; and it cannot be denied that the authors have been desperately earnest in the task of selection and compilation. The body of the work is followed by three main appendices, of which the second is a bibliographic list embodying a none too fortunate selection of books of reference, the third a synopsis of the "animal kingdom," and the first an outline of a course of laboratory work upon the type-organisms selected as titular for the main chapters. Novelty here is as great as with the rest of the book, for in the "Exercises" prescribed, after each type-organism has been referred to its habitat, with brief directions for its capture and preservation in the living state where necessary or desirable, there follow instructions for drawing, and series of questions, framed with a view of compelling the observer to determine details for himself, and not of pointing out the precise nature and limits of the observation he is expected to make, as is customary with most laboratory treatises current. "Hints for observations on the living animal" usually follow, as do "Topics for further study." This very novel scheme is the outcome of experience gained while aiding in the conduct of the zoological affairs of the Harvard University, and as here delimited it is prescribed "for use in schools that can give to the subject five periods per week for half a year," at discretion and with modification determinable by local needs. The book thus embraces a very ambitious programme, and we question if the most hopeful aspect of the undertaking is not simply the better encouragement of field-work and of observation of nature in the open, in respect to which our existing methods do perhaps stand in need of reform.

It appears to us, however, that too much has been attempted within the limits of the book, that there is danger in its too frequent brevity of statement, and that it stands in need of a greater uniformity of treatment. What, for example, is to be gained by merely referring to the Tunicata as "Chordata which are either attached or form colonies, or both" (which is an erroneous statement), and as a group of Invertebrates which "lie nearest to the stem from which the Vertebrates arose," when whole paragraphs are given to far less generally important assemblages of forms? What also the use of defining the Stomatopoda as including "only Squilla," and then Cumacea, Isopoda and Amphipoda as embracing a number of forms? The inclusion of the Sponges in the Cœlenterata; the old-fashioned classification of birds, with the Ratitæ referred to the order "Cursores"; the inclusion of the Bryozoa on one page among the Gephyrea and Leeches ("Annelida"), and on another among the "Scolecida"! can only be cited as examples of classificatory treatment sorely in need of revision; while among definitions given we note a frequent lack of accuracy and precision, as, for example, with that of the Ophidia as having their "eyelids absent." The senior author's previous work explains the introduction of experimental observations of the antenniform-ophthalmite order, and brief note is taken of "variation" and abnormality. The social life and "language" of ants, protective resemblance and mimicry among the Lepidoptera, the habits of the spiders, and many other similarly fascinating topics receive in due course passing consideration. The reader will put down the book feeling the better for its perusal and with a desire to know more, while its "keys" to the identification of the common forms of life, oft overlooked because always present, but withal foremost in their claims on our attention, will prove useful and encouraging. We are doubtful, however, whether the authors would not have done better to have attempted less and that more uniformly, and whether they are justified in their refrain that in matters of elementary scientific education the mere "needs" of the ordinary citizen are to be alone gratified. We are by no means convinced that this argument is sound. Their method would seem likely to discount the teacher's important function of deciding what is to be left untaught—a matter of the utmost urgency in elementary scientific work. We shall watch with interest the development of their scheme.

## COLOUR PHOTOGRAPHY.

*A Handbook of Photography in Colours.* By Thomas Bolas, Alexander A. K. Tallent and Edgar Senior. Pp. viii + 343. (London: Marion and Co., 1900.)

THE preface or introduction is written by the publishers, and is immediately followed by an index. Then follow three "sections." (1) 85 pages, by Mr. Bolas, on the "Historical Development of Heliochromy. General Survey of Processes. Direct Heliochromes on Silver Chloride." (2) 205 pages, by Mr. Tallent, on "Three-colour Photography." (3) 27 pages, by Mr. Senior, on "Lippmann's Process of Interference Heliochromy." Each section is quite distinct from the others, except that they are bound into one volume and indexed together; there is therefore much repetition. For example, Maxwell's colour-sensation curves and Abney's revised curves are each given twice (the two renderings, by the way, are not identical), and Lippmann's formula for his emulsion is given at p. 55 and also at p. 332. Careful editing would have avoided such waste of space. Some of the diagrams are drawn with exceedingly thick lines, and are provided with very large heavy lettering, while others incline rather in the opposite direction. Some of the spectra as drawn for showing absorption, sensitiveness and so on, have the red to the left-, and others the red to the right-hand side; some are normal, and others are as produced by prisms. It may be said that these are quoted from various sources; but in a volume in which it is thought necessary to explain with a large diagram the refraction of light on passing from air into water, surely a little explanation of these differences is desirable. At p. 180, a spectrum which is normal is described as "prismatic." The volume appears not to have been edited at all, therefore the only way to do justice to the authors is to regard it as three distinct books.

Mr. Bolas gives an excellent summary of the whole subject, both historical and practical. As a careful compiler should do, he has erred, if it be an error, in including too much rather than too little. Carey Lea's highly coloured partial reduction products of the halogen salts of silver might have been passed by, by some writers, as well as other references to conjectures. Zenker's work and Wiener's investigations are described intelligibly, although concisely; indeed, the author has evidently spared no pains to give every one his due, and to use to the best advantage the small space at his disposal.

Mr. Tallent begins his section with several pages on the properties of light and the construction of ordinary spectroscopes—matter which, we think, might well have been omitted in order to make room for the treatment of subjects for which the reader is often referred to other books or articles. The peculiar firework-like diagram at p. 112, given to illustrate dispersion, is more likely to mislead than assist the student; and some of the other diagrams might have been made more clear, in spite of the extraordinary boldness of the drawing and lettering. Mr. Tallent has gathered together a great deal of information about three-colour work, which he presents in the form of notes rather than as a treatise. It is doubtless advantageous in some cases to supply the raw material only, but the possession of bricks and mortar does not enable every one to build himself a house. If the very popular style of description sometimes adopted were given up in favour of more technical details, and if the practical applications of the various principles were more closely associated with the enunciation of the principles themselves, we think that the book would be more useful to the large majority of those who will read it. But we must be grateful to Mr. Tallent for having made a beginning in the getting together of the hitherto widely scattered items of the subject. His work must be of considerable assistance to any one following him, and we hope that later on he himself may be able to give us a treatise founded on these notes.

Mr. Senior treats only of Lippmann's interference process, and he writes on this with authority, for he has given the matter much practical attention, and has produced some of the best examples that have been seen. He gives his formulæ and methods apparently without any reserve, as well as the published formulæ of other notable workers. He precedes the practical details with a few pages on the optical principles involved, setting forth clearly the character of "stationary waves." We think that most people reading p. 323 would consider it as showing that the colours reflected from a Lippmann photograph are complementary to those of the objects photographed, but it is quite obvious that Mr. Senior does not intend to convey this impression.

The publishers, in their preface, state that thirty-one years ago they published the pioneer work on photography in colours (by Ducos du Hauron), and they feel satisfaction now in following up the line they "opened up over a quarter of a century ago." All who are interested in the subject will feel thankful to Messrs. Marion and Co. for having done so.

C. J.

## OUR BOOK SHELF.

*Probleme Kritische Studien über den Monismus.* Von Dr. H. v. Schoeler. Pp. viii + 107. (Leipzig: Engelmann, 1900.)

Dr. von Schoeler's critique of monism is the work of a mind which, with all reverence for scientific fact, has nothing but disdain for post-scientific theory. The monism of which Haeckel, for instance, or Romanes is the exponent, has captured many scientific intellects, but it is in Dr. von Schoeler's view an arbitrary conceptual construction. It leaves the problems still with us. Of the ultimates of physics, of biology, of psychology, we know but little, and that little makes against such monism. Life is more than knowledge, and will find emancipation neither in science nor in religion, but in art.

Dr. von Schoeler's discursive criticisms of a variety of attempts at construction, or steps towards construction, are of somewhat unequal value, but not uninteresting. They enter into some detail, and might well give pause to any one who is inclined to build a system without straw to his bricks. But, if it be true that a man's *nay* has no meaning apart from the underlying and implied *yea*, the unsatisfactory character of our author's positive teaching must reflect upon his polemics. The way in which he couples Plato and W. K. Clifford on p. 95 suggests doubts as to his insight. Those who allow that current mechanical theories are tending more and more to immaterialism, that organic evolution reduced to its facts cannot assert even descriptive continuity unhypothetically, and that for a deduction of consciousness from the non-conscious we have not so much as the point of departure, will be left cold by Dr. von Schoeler's appeal for Diploïsmus, and his enthusiasm for Goethe's *Weltanschauung* made complete in the light of Kant's. The duality for which he goes to Bruno's *gemini efficientes* falls even for Dr. von Schoeler within a monism (v. p. 97, ll. 1-4). And Kant's provisional dualism does not exclude a hypothetical monism, idealist or agnostic. Only the resolution of it from the standpoint of understanding is not achievable, and from any other standpoint it cannot be more than hypothetical.

It is doubtful, finally, whether Dr. von Schoeler quite understands in what sense a system admits certain unexplained points as truly problems, and in what sense it claims to solve them. Is the origin of motion a problem recognised by monism as one which it must attempt to solve? And is not metaphysic always, so to speak, a *post mortem* examination? The "gray in gray" of philosophy is a commonplace: "the owl of Athene wings for flight only when twilight falls." H. W. B.

*Diamond Drilling for Gold and other Minerals.* By G. A. Denny. Pp. x + 158. (London: Crosby Lockwood and Son, 1900.)

At the Paris Exhibition of 1867 much interest was aroused by Leschot's invention for cutting through hard rock by diamonds in rapid rotation. Originally intended for use on a small scale, this method was soon applied by Major Beaumont and others to deep boring; and the great improvements made of recent years in the construction of the instruments used, and the large amount of experience that has been gained by their general use in mining districts, have added so much to the importance of the subject of boring, that it is no longer possible to deal with it adequately in a chapter of a general treatise on mining. An independent work is needed. In German, this exists in Tecklenburg's monumental work. In English, however, Mr. Denny's handbook is the first to give a detailed account of the use of modern diamond core-drills in searching for mineral deposits. The work, which covers 158 pages, contains much information of a practical character, including particulars of the cost of apparatus and of working. It is, unfortunately, limited in its scope. South African conditions are alone considered, and the descriptions of the drills are confined to machines made by two American firms. The numerous well-designed drills of English and Continental make are not mentioned. The work cannot, however, fail to be of value to any one contemplating using diamond-drilling machines for the examination of mineral lands in South Africa.

The author gives some interesting results, deduced from his own experience, of the rate of progress of machine diamond drilling in various rocks. For holes up to 1000 feet he finds that, including all normal delays, the rate averages per week: in limestone, 150 to 200 feet; in Carboniferous sandstone, 150 feet; in slate, 100 to 150 feet; in greenstone, 110 feet; in basalt, conglomerate, diabase, diorite and dolomite, 100 feet; in porphyry, 90 feet; in quartz, 85 feet; in granite, 73 feet; and in chert, 60 feet. As regards the cost of drilling, the author points out that diamond drilling on the Witwatersrand is almost always done by contract, the reasons being that men with the requisite experience are not easily secured, and that a mining company rarely has sufficient work to justify the outlay upon the plant. The average tender for a hole 3000 feet deep would work out at about 37*s.* 6*d.* per foot, the price being fixed on a sliding scale, say 25*s.* per foot for the first 500 feet, and rising by 5*s.* per foot every 100 feet. If the company undertook the work on its own account, the cost per foot would be about 26*s.* 8*d.*, or 3950*l.* for the 3000 feet. This with 2340*l.*, the cost of drilling outfit, brings the total cost of the hole to 6290*l.*, as compared with 5625*l.*, the contractors' price. It is to be regretted that the author has not compared these prices with those obtaining elsewhere. The bore-hole at Paruschowitz in Upper Silesia, for example, the deepest in the world, completed to a depth of 6566 feet in 1893, was bored by the diamond drill. The average rate of progress was 16½ feet a day, and the cost was 3761*l.*, or 35*s.* a yard. Details of the average working cost of diamond drills in Victoria and New South Wales, which are published annually in the Government reports, might advantageously have been cited for purposes of comparison. B. H. B.

*Symons's British Rainfall*, 1899. Compiled by H. Sowerby Wallis. Pp. 251. (London: Edward Stanford, 1900.)

A portrait of the late Mr. G. J. Symons, the founder of the British Rainfall Organisation, and an appreciative tribute to his memory, are naturally found in this volume—the first to appear without his name upon the title-page. The thirty-nine volumes for which Mr. Symons was responsible form a real monument to his industry and scientific work. Mr. Sowerby Wallis, who was associated with him for thirty years, will continue the work along the lines which have hitherto proved so successful.

The usual particulars are given concerning the rainfall and meteorology of various parts of the British Isles during the year 1899, as observed at about 3500 stations. The average rainfall of the ten years 1890-1899 is discussed in an article, the values being given for a hundred stations well distributed over the three kingdoms. The discussion is only provisional, but so far as it has gone it indicates that over a large part of the kingdom the rainfall in the period considered was deficient by from 5 to 10 per cent. and upwards. Over an area of about 300 miles long by 100 miles wide, stretching right across the country from south-west to north-east, the fall for the period shows a deficiency of 10 per cent. or more. In other words, accepting the values discussed, it appears that little more than eight and a half years' rain fell over a large part of Central England in the ten years 1890 1899.

## LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### Railways and Moving Platforms.

IN reference to Prof. John Perry's letter in NATURE of Aug. 30 on the subject of "Railways and Moving Platforms," will you kindly allow me to state that I worked out a scheme for moving platforms for railways in India in the year 1877, and that a paper of mine on the subject was published in the professional papers of the Thomason Civil Engineering College at Rurki in India in 1877 or 1878?

My plan was to have alongside of the main line a length of about a mile of level line, with a steep incline at either end, for the moving platform.

The moving platform would acquire sufficient speed on these inclines to run alongside of, and be made fast to, a train on the main line running in the same direction at reduced speed.

After the platform had been made fast, and passengers and crates of luggage transferred to a similar platform on the train, the train was to increase its speed, and finally release the platform with sufficient way on to carry it up the incline at the other end of its run, so as to be in readiness for the next train from the opposite direction.

This represented the case for moving platforms in its simplest form to suit Indian traffic. Details, of course, can readily be supplied.

### The Migration of Swifts.

REFERRING to the letter of Mr. O. H. Latter in NATURE of August 30, there are swifts' nests in the roof of my house, and the birds went to their nests as usual on the evening of August 11, but on the following evening, Sunday, August 12, they had gone. In other houses close at hand swifts remained on the 13th and 14th, but by the evening of the 15th all had disappeared. On one occasion some years ago a solitary swift remained after his companions had departed, and consorted with the neighbouring house martins until the last week in September.

A curious occurrence was observed by me on May 26 last, when the swifts had already been for some time with me But on the afternoon of that day I was on board the Transatlantique Company's steamer crossing the Mediterranean from Marseilles to Algiers in order to observe the total eclipse of the sun. The boat left Marseilles at one o'clock, and at 4h. 40m., by which time we were seventy miles from the land, a flock of birds was seen following the ship in the distance. In a few minutes they were flying round the ship, and turned out to be common swifts. They were estimated to be about 200 in number. They gradually forged ahead, leaving the ship behind, and in a few minutes were lost in the distance. Several of the passengers made a note of the occurrence. The course followed by the swifts was one or two points to the right of the ship's course, or about S.S.W., in the direction of the Balearic Islands.

Steeple Croft, Coventry, September 1.

### The Reform of Mathematical Teaching.

THE deeply interesting letter of Mr. David Mair on the above subject in a recent number of NATURE will no doubt be attentively perused. Many, I imagine, could echo his experience when he says, speaking of 100 boys at a "well-taught school," "hardly one failed to write out the construction and proof, but only one of the hundred carried out the practical construction. Clearly our present Euclidian teaching has little to do with geometry."

Grave dissatisfaction in regard to the study of Euclidian geometry has long been voiced in Great Britain and in France, and the reason for the continued lamentable state of things in that special scientific direction is not, I think, far to seek. When Euclid, as a practical teacher, made use of his Propositions, theory and practice had doubtless that close association which Mr. Mair appears rightly to desire as a remedy for the present extraordinary condition of Euclidian study.

Now, if we assume that Euclid's own pupils were first of all drilled in a thorough knowledge of the sub-geometric properties of the cube, we are led largely to modify the supposed indictment against Euclid's method.

Again, Euclid seems to me to have used constructions, not only of a strict, but of a particular or edificial nature; so that, properly viewed, each succeeding proposition carried, not only its specific teaching or lesson, but beautiful groups also of surrounding truths of an implicit character.

If the foregoing remarks be valid, it is easy to see that only two serious faults can be charged against Euclid's method—namely, the use of false diagrams and indirect demonstrations. The former, of course, being misleading, are not in harmony with the modern Herbartian cumulative principles of "educative instruction."

As to the second fault, the splendid argumentation of the famous Simson in his "Notes" will not, I fear, greatly avail in Euclid's favour. Mr. Mair rightly vindicates for the pupil the power of "educational interest," another Herbartian doctrine, by the by; and I agree with him that "geometry is in worse case than algebra," because with the latter, I opine, the notion of "zero" inevitably leads the mind towards the necessary cubical standard.

No one could reasonably wish the true Euclidian or edificial geometry to be suppressed, but might without presumption press for a reform in the way of presenting all geometrical truths by a direct reference to those sub-geometric conditions which have equal rank with the oldest of nature's immutable laws.

If for any school or pupil, instead of enlarging the mental vision, and creating intellectual joys, the Euclidian tasks savour of prolonged drudgery, mystery and confusion, as they assuredly often do, such toil should perforce be abandoned to prevent, at least, waste of time and energy, not to speak of the gain to human happiness.

Possibly in the broad expanse of the educational economy the universities of the world may eventually suggest practical reforms of a vital kind in the teaching methods that affect mathematical science.

I am not competent to pursue the subject to any length, but I might remind students that, although by a sort of repartee to a kingly personage Euclid said there was "no royal road to geometry," he did not say there was no royal gate to it, and that I trust I have, however faintly, herein indicated.

August 25. HENRY WOOLLEN.

### The Trembling of the Aspen Leaf.

IT is well known that the vibratory motion of the leaf of the aspen and other poplar trees is caused by a flattening of the petiole at its junction with the lamina. The lower part of the leaf-stalk is elongated and rigid, thus forming a basis upon which the flattened portion of the stalk can, in virtue of its elasticity, move to and fro as the wind acts upon the leaves of the tree. It is stated by Kerner that this adaptation prevents the leaves striking against each other and the branches of the tree, whereby they might get bruised. In this connection it is a noticeable fact that the poplars which exhibit this property of leaf-vibration most strongly have sparsely distributed leaves, and the foliage is scanty in comparison with other trees of the genus, especially the abele, or white poplar.

With reference to the abele, it may be noticed that the leaves which possess the trembling motion in a slight degree are covered with a white felting, which Kerner asserts is an adaptation to protect the stomata from the excess of atmospheric moisture which prevails in the damp situations and river-sides where this tree commonly grows. Yet, it may be noted, the aspen is found in precisely similar conditions, and must be affected injuriously by any influence that would act unfavourably upon the abele. Now, it has occurred to me that the real use of the vibratory motion of the aspen leaf may be an adaptation to throw off rapidly the excess of aqueous condensation liable to take place upon the foliage of trees growing in marshy situations. I should very much like to hear the opinions of some of your readers on this point, which, if a true solution of the matter, is interesting from the fact that the same end is secured by very different means in two plants of the same genus, and so very much alike in all other particulars.

Hobart, July 25. **Henry J. Colbourn.**

### Electricity direct from Coal.

With reference to the announcement made in the *Daily Mail* of September 1, that Thomas A. Edison had completed a machine for the generation of electric power direct from coal without the use of engines or dynamos, may I ask you to reprint a few lines from an article on electric traction I wrote for you, and which you published on April 12, 1894?

"Before electric traction can be employed on a very large scale, we must possess a means of producing the electricity on the spot and at the time it has to be used, or, in other words, we must possess a battery in which the energy of coal can be transformed directly into electric current, so that we may do without storage batteries in which to carry electric energy about, or heavy copper conductors through which to convey it at moderately low tension from the spot where it is produced to where it is used, or light aërial conductors through which to convey it at high tension.

"How long we shall be without this, or how many minds are engaged in the solution of this or some such problem, we know not, but the moment it is solved, and solved doubtless it will be, there will be such a transformation scene in the industrial applications of electricity as one can hardly conceive. It would mean that for almost all purposes except those in which heating is required electricity would or could be used. An electric light-producing battery in every house, quite independently of any mains in the streets; an electric power-producing battery to carry us whither we would on rails or on the streets; and in every house to put an end to all the evils attendant on crowded factories and workshops, in crowded streets and towns; such and other advantages would result from turning electricity from a servant into a master, from a mere transformer of energy into a source of energy."

### Artificial Deformations of Heads, and some Customs connected with Polyandry.

With reference to your note on M. Charles de Ujfalvy's recent article in *l'Anthropologie* (p. 323, *ante*), I may be allowed to call your attention to the ancient Korean practice of artificially deforming their heads, which was apparently similar to the method adopted by the Huns as well as the Hûna kings of India. Thus, the Chinese "History of the Later Han Dynasty," written in the fifth century, *sub.* "Eastern Barbarians," says: "The people of Ma-Kan (in the south-western part of the Korean peninsula) wish their heads flat; so the head of every child just born they compress with stone to deform it."

The special horned head-dresses worn by the polyandric women of the White Huns put in mind the old Japanese usages, described by Fujioka and Hirade in their "History of the Japanese Customs and Manners," Tokio, 1897, vol. i. p. 169: "In the festival of the god of Tsukuma, every woman had to go in procession after the holy sedan-chair, with a number of pans on her head proportionate to her immoralities. In the temple of Usaka, while the priest was praying in a feast-day, every woman was scourged on similar principles."

### Huxley and his Work.

On p. 13 of "One Hundred and One Great Writers," issued by the *Standard*, and presumably edited by Dr. Garnett, occurs the following remarkable account of Huxley and his work. "Huxley's work is that of the populariser, *the man who makes few original contributions to science or thought*, but states the discoveries of others better than they could have stated them themselves." Comment is needless. **F. W. Henkel.**

Markree Observatory, Collooney, Ireland, August 23.

## THE CAUSES OF FRACTURE OF STEEL RAILS.

When the down Scotch express was running through St. Neots station, on the Great Northern Railway, on December 10, 1895, a rail broke into seventeen pieces, part of the train left the metals, and a serious accident resulted. Several features of the report on the mishap, drawn up in the ordinary course by the late Sir Francis Marindin, might well have occasioned deep thought, notably the conclusion that the first fracture of the rail took place over a chair at a minute induced flaw, which did not exist when the rail was manufactured.

The whole report, however, is suggestive rather than explanatory, and the result was the appointment by the Board of Trade of a committee to investigate the question of the loss of strength of steel rails caused by prolonged use. The committee was a very strong one, and contained some distinguished steel manufacturers, engineers, metallurgists and chemists. They collected a vast amount of information, much of it apparently considered unsuitable for publication, and made long series of experiments, many of them, judging from the report, more easily made than their results explained.

Finally, after four years' work, they have issued a report with the satisfactory feature that practically no change is recommended to be made in the mode of management of the permanent way by the railway companies.

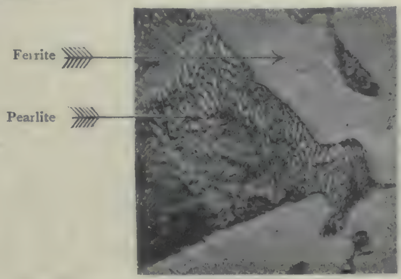

Fig. 1.—Steel rail. × 850 D. Showing pearlite and ferrite.

Nevertheless, although no legislation seems likely to result from the labours of the committee, the evidence that has been collected and published in the appendices to the report is of great scientific interest. The experimental work that was undertaken was divided among the members of the committee. A number of rails found broken on the road, or discarded as worn out, were selected for examination. Prof. Unwin took charge of the tests on their hardness, tensile strength and bending strain, and Mr. Windsor Richards of those on their resistance to the shock of falling weights; Sir William Roberts-Austen made micrographical examination of the rails, and Dr. Thorpe analysed them. Sir Lothian Bell includes in his comprehensive memorandum details of a number of mechanical tests on rails, and Prof. Dunstan gives an interesting account of the effects of atmospheric corrosion.

Interest naturally centred around the St. Neots rail. It was found to be of ordinary composition, and the mechanical tests applied to it showed that the steel was of variable, but, on the whole, of good quality. It was only on microscopic examination that the extraordinary character of the rail became evident. Good rail steel, according to Sir W. Roberts-Austen, consists of "ferrite," or iron free from carbon, and "pearlite," which is a mixture of alternate bands of ferrite and "cementite" (the carbide corresponding to the formula $Fe_3C$). The structure is shown in Fig. 1, a reproduction of a micrograph of rail steel magnified 850 diameters, in which the light constituent is ferrite, and the alternate bands of ferrite and cementite together make up the constituent pearlite. Well-developed pearlite with a conspicuous banded structure is characteristic of good rail steel. It is the form of carbide produced by slow cooling. When, however, steel is hardened by "quenching," pearlite is no longer to be found, and the whole mass consists of interlacing crystalline fibres devoid of banded structure, and is called "martensite."

With regard to this, Sir William Roberts-Austen says: "The detection of martensite in a rail should at once cause it to be viewed with extreme suspicion, as showing that the rail is too hard locally to be safe in use." An examination of the running edge of the St. Neots rail (Fig. 2) showed that a surface layer of about 1/100th of an inch thick existed, in which the carbide was mainly in the form of martensite.

This surface layer forms the lighter upper part of the figure, while the darker portion below it shows the usual assemblage of pearlite and ferrite granules. The actual running edge is shown against the dark space at the top of the figure. Martensite was also found in small patches in some other worn and broken rails, but to a far less extent, the St. Neots rail being unique in this respect.

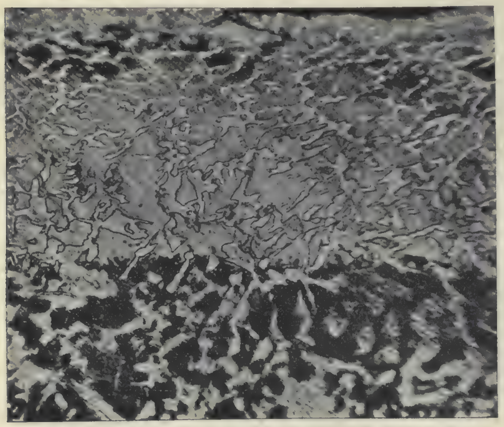

FIG. 2.—St. Neots rail, running edge. Pearlite passing into martensite. × 140 D.

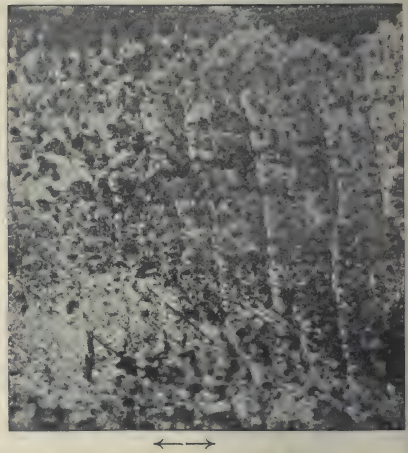

FIG. 3.—St. Neots rail, rolling surface. × 5 D.

The questions that naturally presented themselves on this discovery were, first, How far would this structure account for the brittleness of the rail? and secondly, How had the martensite been produced? With regard to the first question, the rolling surface of the St. Neots rail was found to be traversed by a number of transverse cracks (Fig. 3), some just passing through the hardened skin, others running into the substance of the rail. The upper surfaces of rails are subject to tension over chairs by the weight of passing trains applied between the chairs, and cracks are formed in this way. To realise the importance of these cracks, it is only necessary to turn to Mr. Martin's memorandum. He found that a heavy steel rail nicked with a chisel to a depth of 1/64th of an inch broke under the weight of six hundredweight let fall from a height of twelve feet, while the same rail, if not previously nicked, resisted successfully the fall of a ton weight from a height of twenty feet. The loss of strength due to these minute cracks is therefore amazing, and can only be accounted for on the hypothesis that shallow nicks are readily induced by shock to spread through the mass. The induced flaws of Sir Francis Marindin might thus be explained.

On the other hand, a warning note is struck by Prof. Unwin, who points out that minute transverse fissures are common on the rolling surfaces of old rails; and as only one rail in 2000 or 3000 breaks on the road, the others being discarded as worn out, it must be rare for such fissures to spread into the substance of the rail. It is suggested that if much silicon is present, the spreading of fissures becomes more rapid; but the St. Neots rail contained only 0·09 per cent. of silicon, an amount well within the limits of composition put forward by Messrs. Windsor Richards and Martin as suitable for rail steel.

On considering the problem of how martensite can be formed on the rolling surfaces, it is again evident that the St. Neots rail is a remarkable exception. All old rails become "hammer-hardened" on the surface by long use, and their strength and percentage of elongation may be increased by annealing, but no clear case of any production of martensite in this way could be obtained. The effect produced by the "cold-rolling" action of passing trains on steel is shown in Fig. 4, which is a photograph enlarged 140 diameters of the running edge of a rail taken up after ten years' wear. The direction of the granules is changed in the surface layer, but otherwise the structure is unaltered. Roberts-Austen succeeded in producing a structure like that of the St. Neots rail, but only by local heating with an electric arc. With regard to this, he observes that this experiment "points to the probability that local heating of a rail by skidding, followed as it would be by the rapid abstraction of the heat by the mass of the cold rail, can produce patches of martensite, though it may be very difficult in the laboratory to imitate the actual conditions by mechanical means." He seems to think that "the structure of the St. Neots rail would point to the changes having been effected while the rail was actually in use."

Although the St. Neots rail has thus baffled the committee, inasmuch as they cannot say definitely whether other rails are likely to be altered in the same way, it is evident that one of the most important results of their labours will prove to be the full realisation of the fact that steel possesses a complex structure which can be studied with the microscope, that this structure varies greatly with the mechanical and thermal treatment to which it has been subjected, and that the durability of the rail depends on its structure.

Apart from the micrographical appendices, much interesting information may be obtained from a study of the mechanical tests, and some of the conclusions drawn by Prof. Unwin from these are among the most definite in the report, though they do not go far to explain the St. Neots mishap. It is found, for instance, that rails generally break near their ends "owing to greater straining action due to discontinuity at the joint," and that the fish-joints are an unavoidable source of danger. It is also found that a rail is more liable to break when its worn head is turned down, as usually happens after a few years' use in the case of double-headed rails. Considerations of space alone prevent these points from being dealt with at greater length.

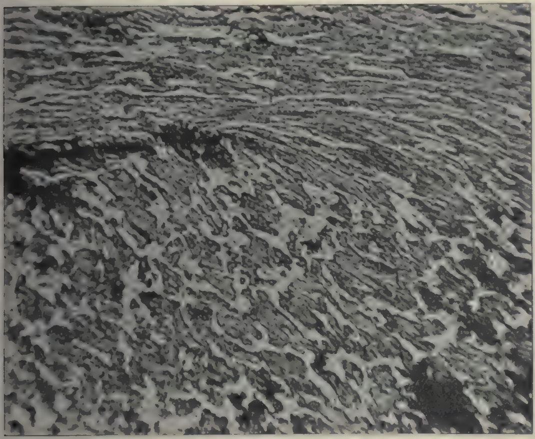

FIG. 4 —Running edge showing "flow." × 140 D.

## THE BRADFORD MEETING OF THE BRITISH ASSOCIATION.

THE final arrangements for the Bradford meeting of the British Association are now complete, and there is every indication that the gathering will be one of the largest that has been held in recent years. Representatives of scientific institutions are coming from nearly every country in the world; and there are delegates from the United States, Canada, the Cape, New Zealand, the West Indies, India, France, Germany, Russia, Denmark and Sweden, Spain, Italy and Greece. The Bradford people have come forward in a most willing manner to offer hospitality to the visitors, and a large proportion of the strangers will at any rate have had the opportunity of accepting private hospitality.

In our last article we dealt with the excursion programme. We propose now to say something about the various social functions which have been organised for the week.

The first social gathering will be a reception at the Municipal Technical College this afternoon (September 6). Mr. W. E. B. Priestley, the chairman of the Technical Instruction Committee, will welcome the visitors; and, after partaking of afternoon tea, they will be escorted in small bodies round the building, to see the textile exhibition, and the various processes of the textile industries. On the evening of the same day (Thursday) the Mayor and Mayoress have invited the Association to a conversazione in St. George's Hall. The building will be elaborately decorated, and music will be provided by a large string band, under the conductorship of Mr. I. Shepherd. There will be exhibits of various scientific novelties in different parts of the building; and the galleries will be specially levelled-up for refreshment and supper buffets. The 2nd West York Artillery Volunteers are providing a Guard of Honour to line the staircase.

At the conclusion of Prof. Gotch's lecture on Friday night there will be a smoking concert at the Technical College in honour of the President, for which various well-known elocutionists have been engaged.

On Monday, September 10, the Mayor and Corporation are inviting all persons attending the meeting to a large garden-party in Lister Park. The portion of the park where the guests will chiefly collect will be that above the lake. Around or in this space there will be several refreshment tents, and in front of each will be little tables in the open, surrounded by chairs, after the style of the foreign *cafés*. The lake will be decorated by means of Venetian masts and flags; while some new boats will be out, with boatmen in suitable garb in charge of them. The Black Dyke Band plays near the lake, and the band of the Bradford Rifles at the high end of the park. Archery and other amusements will be provided; and in one corner there will be some ballooning experiments under the direction of the Rev. J. M. Bacon, who is well known just now in connection with the trials which, in conjunction with Admiral Fremantle, he has been making in improved military signalling from balloons. Probably Mr. Bacon will be accompanied by the Admiral. It is proposed to erect a 70-foot pole about 30 yards from the balloon, and another, of equal height, in the furthest corner of the park; and, somewhere between the two, it will be attempted to explode a mine by means of wireless telegraphy, an experiment which was recently successfully performed at Newbury. Mr. Nevil Maskelyne will take part in the wireless telegraphic experiments, in order to exhibit the new receiver which he has patented and sold to Lloyd's.

On Tuesday the Mayor and Corporation are inviting the Association to a soirée in St. George's Hall. The arrangements will be somewhat similar to those on the occasion of the Mayor's function on the preceding Thursday, excepting that the music will be provided by the band of the Artillery Volunteers.

On Wednesday various private garden-parties will take place. Mrs. Henry Illingworth has invited 150 members of the Association to visit her grounds, for tea, tennis and croquet; and there will be music for those who prefer to rest after their labours. There will also be a garden-party at Ferniehurst, Baildon, by the kind invitation of Mr. and Mrs. G. C. Waud; a procession of prize-winning hackneys will take place in the course of the afternoon; and also sheep-dog trials, for which most of the celebrated dogs in the North Country have been brought together.

Messrs. Wm. Fison and Co. have also invited a hundred members to a garden-party at Greenholme, where, after tea, they will have an opportunity of visiting the turbine machinery and their textile works. Another function on the same day will be a garden-party at Royds Hall, by the kind invitation of the Low Moor Iron Company. The visitors will first be taken round the foundries to see some smelting work, and to examine some of the most striking parts of the machinery.

On the evening of Wednesday (the 12th) there will be a grand concert in St. George's Hall, at which Madame Ella Russell will be the *primâ donna*. The Bradford Permanent Orchestra, under the conductorship of Mr. Frederick Cowen, will render a very interesting programme; and the Festival Choral Society are to perform certain celebrated items from the works of Handel, Wagner and Sullivan.

A temporary museum, illustrative of papers read before the Sections, will be provided in the Girls' Grammar School. Its primary object is to afford a space where those who read papers can deposit any specimens or apparatus which they may show, and which thus can be examined more at leisure than in the Section Room. In addition, the Bradford officials have endeavoured to get together some choice geological specimens of local interest, which will illustrate the discussions to take place in the Geological and Botanical Sections on the origin of coal; and also specimens illustrating the reef-knolls of the Craven district, which have been the subject of controversy in recent years. Further, Mr. Butler Wood, the chief librarian under the Bradford Corporation, has taken under his care a collection of local pre-historic specimens.

Amongst the readers of papers, Mr. J. J. Stead, of Middlesbrough, will exhibit specimens of metals, treated by a peculiar method which he has discovered. There will be numerous maps, principally geological—several dealing with the investigation of the underground water-courses of Malham and Ingleborough. There will also be a contribution, by Mr. A. D. Ellis, of a number of rare and valuable atlases, of the sixteenth to the eighteenth centuries; while various lantern slides used in the Sections will be shown on transparent screens. In addition, the Science and Art Department have promised the loan of the best work that was done in the recent National Competition; and the collection from South Kensington is expected to be of an exceptionally attractive character, representing, as it does, the cream of the best work of the Art Schools of the country. It is intended that the exhibits shall be largely illustrative of the products of Bradford, and that they shall also illustrate, to a certain extent, the work that is being done at the Municipal Technical College.

RAMSDEN BACCHUS.

## INAUGURAL ADDRESS BY PROF. SIR WILLIAM TURNER, M.B., D.C.L., D.Sc., F.R.S., PRESIDENT OF THE ASSOCIATION.

TWENTY-SEVEN years ago the British Association met in Bradford, not at that time raised to the dignity of a City. The meeting was very successful, and was attended by about 2000 persons—a forecast, let us hope, of what we may expect at the present assembly. A distinguished chemist, Prof. A. W. Williamson, presided. On this occasion the Association has selected for the presidential chair one whose attention has been given to the study of an important department of biological science. His claim to occupy, however unworthily, the distinguished position in which he has been placed rests, doubtless, on the fact that, in the midst of engrossing duties devolving on a teacher in a great University and School of Medicine, he has endeavoured to contribute to the sum of knowledge of the science which he professes. It is a matter of satisfaction to feel that the success of a meeting of this kind does not rest upon the shoulders of the occupant of the presidential chair, but is due to the eminence and active co-operation of the men of science who either preside over or engage in the work of the nine or ten sections into which the Association is divided, and to the energy and ability for organisation displayed by the local Secretaries and Committees. The programme prepared by the general and local officers of the Association shows that no efforts have been spared to provide an ample bill of fare, both in its scientific and social aspects. Members and Associates will, I feel sure, take away from the Bradford Meeting as pleasant memories as did our colleagues of the corresponding Association Française, when, in friendly collaboration at Dover last year, they testified to the common citizenship of the Universal Republic of Science. As befits a leading centre of industry in the great county of York, the applications of science to the industrial arts and to agriculture will form subjects of discussion in the papers to be read at the meeting.

Since the Association was at Dover a year ago, two of its former Presidents have joined the majority. The Duke of Argyll presided at the meeting in Glasgow so far back as 1855. Throughout his long and energetic life, he proved himself to be an eloquent and earnest speaker, one who gave to the consideration of public affairs a mind of singular independence, and a thinker and writer in a wide range of human knowledge. Sir J. Wm. Dawson was President at the meeting in Birmingham in 1886. Born in Nova Scotia in 1820, he devoted himself to the study of the Geology of Canada, and became the leading authority on the subject. He took also an active and influential part in promoting the spread of scientific education in the Dominion, and for a number of years he was Principal and Vice-Chancellor of the M'Gill University, Montreal.

### *Scientific Method.*

Edward Gibbon has told us that diligence and accuracy are the only merits which an historical writer can ascribe to himself. Without doubt they are fundamental qualities necessary for historical research, but in order to bear fruit they require to be exercised by one whose mental qualities are such as to enable him to analyse the data brought together by his diligence, to discriminate between the false and the true, to possess an insight into the complex motives that determine human action, to be able to recognise those facts and incidents which had exercised either a primary or only a secondary influence on the affairs of nations, or on the thoughts and doings of the person whose character he is depicting.

In scientific research, also, diligence and accuracy are fundamental qualities. By their application new facts are discovered and tabulated, their order of succession is ascertained, and a wider and more intimate knowledge of the processes of nature is acquired. But to decide on their true significance a well-balanced mind and the exercise of prolonged thought and reflection are needed. William Harvey, the father of exact research in physiology, in his memorable work, "De Motu Cordis et Sanguinis," published more than two centuries ago, tells us of the great and daily diligence which he exercised in the course of his investigations, and the numerous observations and experiments which he collated. At the same time he refers repeatedly to his cogitations and reflections on the meaning of what he had observed, without which the complicated movements of the heart could not have been analysed, their significance determined, and the circulation of the blood in a continuous stream definitely established. Early in the present century, Carl Ernst von Baer, the father of embryological research, showed the importance which he attached to the combination of observation with meditation by placing side by side on the title page of his famous treatise, "Ueber Entwickelungsgeschichte der Thiere" (1828), the words *Beobachtung und Reflexion.*

Though I have drawn from biological science my illustrations of the need of this combination, it must not be inferred that it applies exclusively to one branch of scientific inquiry; the conjunction influences and determines progress in all the sciences, and when associated with a sufficient touch of imagination, when the power of seeing is conjoined with the faculty of foreseeing, of projecting the mind into the future, we may expect something more than the discovery of isolated facts; their co-ordination and the enunciation of new principles and laws will necessarily follow.

Scientific method consists, therefore, in close observation, frequently repeated so as to eliminate the possibility of erroneous seeing; in experiments checked and controlled in every direcin which fallacies might arise; in continuous reflection on the appearances and phenomena observed, and in logically reasoning out their meaning and the conclusions to be drawn from them. Were the method followed out in its integrity by all who are engaged in scientific investigations, the time and labour expended in correcting errors committed by ourselves or by other observers and experimentalists would be saved, and the volumes devoted annually to scientific literature would be materially diminished in size. Were it applied, as far as the conditions of life admit, to the conduct and management of human affairs, we should not require to be told, when critical periods in our welfare as a nation arise, that we shall muddle through somehow. Recent experience has taught us that wise discretion and careful prevision are as necessary in the direction of public affairs as in the pursuit of science, and in both instances, when properly exercised, they enable us to reach with comparative certainty the goal which we strive to attain.

### *Improvements in Means of Observation.*

Whilst certain principles of research are common to all the sciences, each great division requires for its investigation specialised arrangements to insure its progress. Nothing contributes so much to the advancement or knowledge as improvements in the means of observation, either by the discovery of new adjuncts to research, or by a fresh adaptation of old methods. In the industrial arts, the introduction of a new kind of raw material, the recognition that a mixture or blending is often more serviceable than when the substances employed are uncombined, the discovery of new processes of treating the articles used in manufactures, the invention of improved machinery, all lead to the expansion of trade, to the occupation of the people, and to the development of great industrial centres. In science, also, the invention and employment of new and more precise instruments and appliances enable us to appreciate more clearly the signification of facts and phenomena which were previously obscure, and to penetrate more deeply into the mysteries of nature. They mark fresh departures in the history of science, and provide a firm base of support from which a continuous advance may be made and fresh conceptions of nature can be evolved.

It is not my intention, even had I possessed the requisite knowledge, to undertake so arduous a task as to review the progress which has recently been made in the great body of sciences which lie within the domain of the British Association. As my occupation in life has required me to give attention to the science which deals with the structure and organisation of the bodies of man and animals—a science which either includes within its scope or has intimate and widespread relations to comparative anatomy, embryology, morphology, zoology, physiology and anthropology—I shall limit myself to the attempt to bring before you some of the more important observations and conclusions which have a bearing on the present position of the subject. As this is the closing year of the century it will not, I think, be out of place to refer to the changes which a hundred years have brought about in our fundamental conceptions of the structure of animals. In science, as in business, it is well from time to time to take stock of what we have been doing, so that we may realise where we stand and ascertain the balance to our credit in the scientific ledger.

So far back as the time of the ancient Greeks it was known that the human body and those of the more highly organised animals were not homogeneous, but were built up of parts, the *partes dissimilares* (τὰ ἀνόμοια μέρη) of Aristotle, which differed from each other in form, colour, texture, consistency and properties. These parts were familiarly known as the bones, muscles, sinews, blood-vessels, glands, brain, nerves and so on. As the centuries] rolled on, and as observers and observations multiplied, a more and more precise knowledge of these parts throughout the Animal Kingdom was obtained, and various attempts were made to classify animals in accordance with their forms and structure. During the concluding years of the last century and the earlier part of the present, the Hunters, William and John, in our country, the Meckels in Germany, Cuvier and St. Hilaire in France, gave an enormous impetus to anatomical studies, and contributed largely to our knowledge of the construction of the bodies of animals. But whilst by these and other observers the most salient and, if I may use the expression, the grosser characters of animal organisation had been recognised, little was known of the more intimate structure or texture of the parts. So far as could be determined by the unassisted vision, and so much as could be recognised by the use of a simple lens, had indeed been ascertained, and it was known that muscles, nerves and tendons were composed of threads or fibres, that the blood- and lymph-vessels were tubes, that the parts which we call fasciæ and aponeuroses were thin membranes, and so on.

Early in the present century Xavier Bichat, one of the most brilliant men of science during the Napoleonic era in France, published his "Anatomie Géneral," in which he formulated important general principles. Every animal is an assemblage of different organs, each of which discharges a function, and acting together, each in its own way, assists in the preservation of the whole. The organs are, as it were, special machines situated in the general building which constitutes the factory or body of the individual. But, further, each organ or special machine is itself formed of tissues which possess different properties. Some, as the blood-vessels, nerves, fibrous tissues, &c., are generally distributed throughout the animal body, whilst others, as bones, muscles, cartilage, &c., are found only in certain definite localities. Whilst Bichat had acquired a definite philosophical conception of the general principles of construction and of the distribution of the tissues, neither he nor his pupil Béclard was in a position to determine the essential nature of the structural elements. The means and appliances at their disposal and at that of other observers in their generation were not sufficiently potent to complete the analysis.

Attempts were made in the third decennium of this century to improve the methods of examining minute objects by the manufacture of compound lenses, and by doing away with chromatic and spherical aberration, to obtain, in addition to magnification of the object, a relatively large flat field of vision with clearness and sharpness of definition. When in January 1830 Joseph Jackson Lister read to the Royal Society his memoir "On some properties in achromatic object-glasses applicable to the improvement of microscopes," he announced the principles on which combinations of lenses could be arranged, which would possess these qualities. By the skill of our opticians, microscopes have now for more than half a century been constructed which, in the hands of competent observers, have influenced and extended biological science with results comparable to those obtained by the astronomer through improvements in the telescope.

In the study of the minute structure of plants and animals the observer has frequently to deal with tissues and organs, most of which possess such softness and delicacy of substance and outline that, even when microscopes of the best construction are employed, the determination of the intimate nature of the tissue, and the precise relation which one element of an organ bears to the other constituent elements, is in many instances a matter of difficulty. Hence additional methods have had to be devised in order to facilitate study and to give precision and accuracy to our observations. It is difficult for one of the younger generation of biologists, with all the appliances of a well-equipped laboratory at his command, with experienced teachers to direct him in his work, and with excellent text-books, in which the modern methods are described, to realise the conditions under which his predecessors worked half a century ago. Laboratories for minute biological research had not been constructed, the practical teaching of histology and embryology had not been organised, experience in methods of work had not accumulated; each man was left to his individual efforts, and had to puzzle his way through the complications of structure to the best of his power. Staining and hardening reagents were unknown. The double-bladed knife invented by Valentin, held in the hand, was the only improvement on the scalpel or razor for cutting thin, more or less translucent slices suitable for microscopic examination; mechanical section-cutters and freezing arrangements had not been devised. The tools at the disposal of the microscopist were little more than knife, forceps, scissors, needles, with acetic acid, glycerine and Canada balsam as reagents. But in the employment of the newer methods of research, care has to be taken, more especially when hardening and staining reagents are used, to discriminate between appearances which are to be interpreted as indicating natural characters, and those which are only artificial productions.

Notwithstanding the difficulties attendant on the study of the more delicate tissues, the compound achromatic microscope provided anatomists with an instrument of great penetrative power. Between the years 1830 and 1850 a number of acute observers applied themselves with much energy and enthusiasm to the examination of the minute structure of the tissues and organs in plants and animals.

### *Cell Theory.*

It had, indeed, long been recognised that the tissues of plants were to a large extent composed of minute vesicular bodies, technically called cells (Hooke, Malpighi, Grew). In 1831 the discovery was made by the great botanist, Robert Brown, that in many families of plants a circular spot, which he named areola or nucleus, was present in each cell; and in 1838 M. J. Schleiden published the fact that a similar spot or nucleus was a universal elementary organ in vegetables. In the tissues of animals also structures had begun to be recognised comparable with the cells and nuclei of the vegetable tissues, and in

1839 Theodore Schwann announced the important generalisation that there is one universal principle of development for the elementary part of organisms, however different they may be in appearance, and that this principle is the formation of cells. The enunciation of the fundamental principle that the elementary tissues consisted of cells constituted a step in the progress of biological science which will for ever stamp the century now drawing to a close with a character and renown equalling those which it has derived from the most brilliant discoveries in the physical sciences. It provided biologists with the visible anatomical units through which the external forces operating on, and the energy generated in, living matter come into play. It dispelled for ever the old mystical idea of the influence exercised by vapours or spirits in living organisms. It supplied the physiologist and pathologist with the specific structures through the agency of which the functions of organisms are discharged in health and disease. It exerted an enormous influence on the progress of practical medicine. A review of the progress of knowledge of the cell may appropriately enter into an address on this occasion.

### *Structure of Cells.*

A cell is a living particle, so minute that it needs a microscope for its examination; it grows in size, maintains itself in a state of activity, responds to the action of stimuli, reproduces its kind, and in the course of time it degenerates and dies.

Let us glance at the structure of a cell to determine its constituent parts and the *rôle* which each plays in the function to be discharged. The original conception of a cell, based upon the study of the vegetable tissues, was a minute vesicle enclosed by a definite wall, which exercised chemical or metabolic changes on the surrounding material and secreted into the vesicle its characteristic contents. A similar conception was at first also entertained regarding the cells of animal tissues; but as observations multiplied, it was seen that numerous elementary particles, which were obviously in their nature cells, did not possess an enclosing envelope. A wall ceased to have a primary value as a constituent part of a cell, the necessary vesicular character of which therefore could no longer be entertained.

The other constituent parts of a cell are the cell plasm, which forms the body of the cell, and the nucleus embedded in its substance. Notwithstanding the very minute size of the nucleus, which even in the largest cells is not more than 1/500th inch in diameter, and usually is considerably smaller, its almost constant form, its well-defined sharp outline, and its power of resisting the action of strong reagents when applied to the cell have from the period of its discovery by Robert Brown caused histologists to bestow on it much attention. Its structure and chemical composition; its mode of origin; the part which it plays in the formation of new cells and its function in nutrition and secretion have been investigated.

When examined under favourable conditions in its passive or resting state, the nucleus is seen to be bounded by a membrane which separates it from the cell plasm and gives it the characteristic sharp contour. It contains an apparently structureless nuclear substance, nucleoplasm or enchylema, in which are embedded one or more extremely minute particles called nucleoli, along with a network of exceedingly fine threads or fibres, which in the active living cell play an essential part in the production of new nuclei within the cell. In its chemical composition the nuclear substance consists of albuminous plastin and globulin; and of a special material named nuclein, rich in phosphorus and with an acid reaction. The delicate network within the nucleus consists apparently of the nuclein, a substance which stains with carmine and other dyes, a property which enables the changes, which take place in the network in the production of young cells, to be more readily seen and followed out by the observer.

The mode of origin of the nucleus and the part which it plays in the production of new cells have been the subject of much discussion. Schleiden, whose observations, published in 1838, were made on the cells of plants, believed that within the cell a nucleolus first appeared, and that around it molecules aggregated to form the nucleus. Schwann again, whose observations were mostly made on the cells of animals, considered that an amorphous material existed in organised bodies, which he called cytoblastema. It formed the contents of cells, or it might be situated free or external to them. He figuratively compared it to a mother liquor in which crystals are formed. Either in the cytoblastema within the cells or in that situated external to them, the aggregation of molecules around a nucleolus to form a nucleus might occur, and, when once the nucleus had been formed, in its turn it would serve as a centre of aggregation of additional molecules from which a new cell would be produced. He regarded therefore the formation of nuclei and cells as possible in two ways: one within pre-existing cells (endogenous cell-formation), the other in a free blastema lying external to cells (free cell-formation). In animals, he says, the endogenous method is rare, and the customary origin is in an external blastema. Both Schleiden and Schwann considered that after the cell was formed the nucleus had no permanent influence on the life of the cell, and usually disappeared.

Under the teaching principally of Henle, the famous Professor of Anatomy in Göttingen, the conception of the free formation of nuclei and cells in a more or less fluid blastema, by an aggregation of elementary granules and molecules, obtained so much credence, especially amongst those who were engaged in the study of pathological processes, that the origin of cells within pre-existing cells was to a large extent lost sight of. That a parent cell was requisite for the production of new cells seemed to many investigators to be no longer needed. Without doubt this conception of free cell-formation contributed in no small degree to the belief, entertained by various observers, that the simplest plants and animals might arise, without pre-existing parents, in organic fluids destitute of life, by a process of spontaneous generation; a belief which prevailed in many minds almost to the present day. If, as has been stated, the doctrine of abiogenesis cannot be experimentally refuted, on the other hand it has not been experimentally proved. The burden of proof lies with those who hold the doctrine, and the evidence that we possess is all the other way.

### *Multiplication of Cells.*

Although von Mohl, the botanist, seems to have been the first to recognise (1835) in plants a multiplication of cells by division, it was not until attention was given to the study of the egg in various animals, and to the changes which take place in it, attendant on fertilisation, that in the course of time a much more correct conception of the origin of the nucleus and of the part which it plays in the formation of new cells was obtained. Before Schwann had published his classical memoir in 1839, von Baer and other observers had recognised within the animal ovum the germinal vesicle, which obviously bore to the ovum the relation of a nucleus to a cell. As the methods of observation improved, it was recognised that, within the developing egg, two vesicles appeared where one only had previously existed, to be followed by four vesicles, then eight, and so on in multiple progression until the ovum contained a multitude of vesicles, each of which possessed a nucleus. The vesicles were obviously cells which had arisen within the original germ-cell or ovum. These changes were systematically described by Martin Barry so long ago as 1839 and 1840 in two memoirs communicated to the Royal Society of London, and the appearance produced, on account of the irregularities of the surface occasioned by the production of new vesicles, was named by him the mulberry-like structure. He further pointed out that the vesicles arranged themselves as a layer within the envelope of the egg or zona pellucida, and that the whole embryo was composed of cells filled with the foundations of other cells. He recognised that the new cells were derived from the germinal vesicle or nucleus of the ovum, the contents of which entered into the formation of the first two cells, each of which had its nucleus, which in its turn resolved itself into other cells, and by a repetition of the process into a greater number. The endogenous origin of new cells within a pre-existing cell and the process which we now term the segmentation of the yolk were successfully demonstrated. In a third memoir, published in 1841, Barry definitely stated that young cells originated through division of the nucleus of the parent cell, instead of arising, as a product of crystallisation, in the fluid cytoblastema of the parent cell or in a blastema situated external to the cell.

In a memoir published in 1842, John Goodsir advocated the view that the nucleus is the reproductive organ of the cell, and that from it, as from a germinal spot, new cells were formed. In a paper, published three years later, on nutritive centres, he described cells the nuclei of which were the permanent source of successive broods of young cells, which from time to time occupied the cavity of the parent cell. He extended also his observations on the endogenous formation of cells to the cartilage cells in the process of inflammation and to other tissues undergoing pathological changes. Corroborative observations on endogenous formation were also given by his brother, Harry Goodsir, in 1845. These observations on the part which the nucleus plays by cleavage in the formation of young cells by endogenous development from a parent centre—that an organic continuity existed between a mother cell and its descendants through the nucleus—constituted a great step in advance of the views entertained by Schleiden and Schwann, and showed that Barry and the Goodsirs had a deeper insight into the nature and functions of cells than was possessed by most of their contemporaries, and are of the highest importance when viewed in the light of recent observations.

In 1841 Robert Remak published an account of the presence of two nuclei in the blood corpuscles of the chick and the pig, which he regarded as evidence of the production of new corpuscles by division of the nucleus within a parent cell; but it was not until some years afterwards (1850 to 1855) that he recorded additional observations and recognised that division of the nucleus was the starting-point for the multiplication of cells in the ovum and in the tissues generally. Remak's view was that the process of cell-division began with the cleavage of the nucleolus, followed by that of the nucleus, and that again by cleavage of the body of the cell and of its membrane. Kölliker had previously, in 1843, described the multiplication of nuclei in the ova of parasitic worms, and drew the inference that in the formation of young cells within the egg the nucleus underwent cleavage, and that each of its divisions entered into the formation of a new cell. By these observations, and by others subsequently made, it became obvious that the multiplication of animal cells, either by division of the nucleus within the cell, or by the budding off of a part of the protoplasm of the cell, was to be regarded as a widely spread and probably a universal process, and that each new cell arose from a parent cell.

Pathological observers were, however, for the most part inclined to consider free cell-formation in a blastema or exudation by an aggregation of molecules, in accordance with the views of Henle, as a common phenomenon. This proposition was attacked with great energy by Virchow in a series of memoirs published in his "Archiv," commencing in vol. i. 1847, and finally received its death-blow in his published lectures on Cellular Pathology, 1858. He maintained that in pathological structures there was no instance of cell development *de novo*; where a cell existed, there one must have been before. Cell-formation was a continuous development by descent, which he formulated in the expression *omnis cellula e cellulâ*.

### *Karyokinesis.*

Whilst the descent of cells from pre-existing cells by division of the nucleus during the development of the egg, in the embryos of plants and animals, and in adult vegetable and animal tissues, both in healthy and diseased conditions, had now become generally recognised, the mechanism of the process by which the cleavage of the nucleus took place was for a long time unknown. The discovery had to be deferred until the optician had been able to construct lenses of a higher penetrative power, and the microscopist had learned the use of colouring agents capable of dyeing the finest elements of the tissues. There was reason to believe that in some cases a direct cleavage of the nucleus, to be followed by a corresponding division of the cell into two parts, did occur. In the period between 1870 and 1880 observations were made by Schneider, Strasburger, Bütschli, Fol, van Beneden and Flemming, which showed that the division of the nucleus and the cell was due to a series of very remarkable changes, now known as indirect nuclear and cell division, or karyokinesis. The changes within the nucleus are of so complex a character that it is impossible to follow them in detail without the use of appropriate illustrations. I shall have to content myself, therefore, with an elementary sketch of the process.

I have previously stated that the nucleus in its passive or resting stage contains a very delicate network of threads or fibres. The first stage in the process of nuclear division consists in the threads arranging themselves in loops and forming a compact coil within the nucleus. The coil then becomes looser, the loops of threads shorten and thicken, and somewhat later each looped thread splits longitudinally into two portions. As the threads stain when colouring agents are applied to them, they are called chromatin fibres, and the loose coil is the chromosome (Waldeyer).

As the process continues, the investing membrane of the nucleus disappears, and the loops of threads arrange themselves within the nucleus so that the closed ends of the loops are directed to a common centre, from which the loops radiate outwards and produce a starlike figure (aster). At the same time clusters of extremely delicate lines appear both in the nucleoplasm and in the body of the cell, named the achromatic figure, which has a spindle-like form with two opposite poles, and stains much more feebly than the chromatic fibres. The loops of the chromatic star then arrange themselves in the equatorial plane of the spindle, and bending round turn their closed ends towards the periphery of the nucleus and the cell.

The next stage marks an important step in the process of division of the nucleus. The two longitudinal portions, into which each looped thread had previously split, now separate from each other, and whilst one part migrates to one pole of the spindle, the other moves to the opposite pole, and the free ends of each loop are directed towards its equator (metakinesis). By this division of the chromatin fibres, and their separation from each other to opposite poles of the spindle, two starlike chromatin figures are produced (dyaster).

Each group of fibres thickens, shortens, becomes surrounded by a membrane, and forms a new or daughter nucleus (dispirem). Two nuclei therefore have arisen within the cell by the division of that which had previously existed, and the expression formulated by Flemming—*omnis nucleus e nucleo*—is justified. Whilst this stage is in course of being completed, the body of the cell becomes constricted in the equatorial plane of the spindle, and, as the constriction deepens, it separates into two parts, each containing a daughter nucleus, so that two nucleated cells have arisen out of a pre-existing cell.

A repetition of the process in each of these cells leads to the formation of other cells, and, although modifications in details are found in different species of plants and animals, the multiplication of cells in the egg and in the tissues generally on similar lines is now a thoroughly established fact in biological science.

In the study of karyokinesis, importance has been attached to the number of chromosomes in the nucleus of the cell. Flemming had seen in the Salamander twenty-four chromosome fibres, which seems to be a constant number in the cells of epithelium and connective tissues. In other cells again, especially in the ova of certain animals, the number is smaller, and fourteen, twelve, four, and even two only have been described. The theory formulated by Boveri that the number of chromosomes is constant for each species, and that in the karyokinetic figures corresponding numbers are found in homologous cells, seems to be not improbable.

In the preceding description I have incidentally referred to the appearance in the proliferating cell of an achromatic spindle-like figure. Although this was recognised by Fol in 1873, it is only during the last ten or twelve years that attention has been paid to its more minute arrangements and possible signification in cell-division.

The pole at each end of the spindle lies in the cell plasm which surrounds the nucleus. In the centre of each pole is a somewhat opaque spot (central body) surrounded by a clear space, which, along with the spot, constitutes the centrosome or the sphere of attraction. From each centrosome extremely delicate lines may be seen to radiate in two directions. One set extends towards the pole at the opposite end of the spindle, and, meeting or coming into close proximity with radiations from it, constitutes the body of the spindle, which, like a perforated mantle, forms an imperfect envelope around the nucleus during the process of division. The other set of radiations is called the polar, and extends in the region of the pole towards the periphery of the cell.

The question has been much discussed whether any constituent part of the achromatic figure, or the entire figure, exists in the cell as a permanent structure in its resting phase; or if it is only present during the process of karyokinesis. During the development of the egg the formation of young cells, by division of the segmentation nucleus, is so rapid and continuous that the achromatic figure, with the centrosome in the pole of the spindle, is a readily recognisable object in each cell. The polar and spindle-like radiations are in evidence during karyokinesis, and have apparently a temporary endurance and function. On the other hand, van Beneden and Boveri were of opinion that the central body of the centrosome did not disappear when the division of the nucleus came to an end, but that it remained as a constituent part of a cell lying in the cell plasm near to the nucleus. Flemming has seen the central body with its sphere in leucocytes, as well as in epithelial cells and those of othe tissues. Subsequently Heidenhain and other histologists have recorded similar observations. It would seem, therefore, as if there were reason to regard the centrosome, like the nucleus, as a permanent constituent of a cell. This view, however, is not universally entertained. If not always capable of demonstration in the resting stage of a cell, it is doubtless to be regarded as potentially present, and ready to assume, along with the radiations, a characteristic appearance when the process of nuclear division is about to begin.

One can scarcely regard the presence of so remarkable an appearance as the achromatic figure without associating with it an important function in the economy of the cell. As from the centrosome at the pole of the spindle both sets of radiations diverge, it is not unlikely that it acts as a centre or sphere of energy and attraction. By some observers the radiations are regarded as substantive fibrillar structures, elastic or even contractile in their properties. Others, again, look upon them as morphological expressions of chemical and dynamical energy in the protoplasm of the cell body. On either theory we may assume that they indicate an influence, emanating, it may be, from the centrosome, and capable of being exercised both on the cell plasm and on the nucleus contained in it. On the contractile theory, the radiations which form the body of the spindle, either by actual traction of the supposed fibrillæ or by their pressure on the nucleus which they surround, might impel during karyokinesis the dividing chromosome elements towards the poles of the spindle, to form there the daughter nuclei. On the dynamical theory, the chemical and physical energy in the centrosome might influence the cell plasm and the nucleus, and attract the chromosome elements of the nucleus to the poles of the spindle. The radiated appearance would therefore be consequent and attendant on the physico-chemical activity of the centrosome. One or other of these theories may also be applied to the interpretation of the significance of the polar radiations.

### *Cell Plasm.*

In the cells of plants, in addition to the cell wall, the cell body and the cell juice require to be examined. The material of the cell body, or the cell contents, was named by von Mohl (1846) protoplasm, and consisted of a colourless tenacious substance which partly lined the cell wall (primordial utricle), and partly traversed the interior of the cell as delicate threads enclosing spaces (vacuoles) in which the cell juice was contained. In the protoplasm the nucleus was embedded. Nägeli, about the same time, had also recognised the difference between the protoplasm and the other contents of vegetable cells, and had noticed its nitrogenous composition.

Though the analogy with a closed bladder or vesicle could no longer be sustained in the animal tissues, the name "cell" continued to be retained for descriptive purposes, and the body of the cell was spoken of as a more or less soft substance enclosing a nucleus (Leydig). In 1861 Max Schultze adopted for the substance forming the body of the animal cell the term "protoplasm." He defined a cell to be a particle of protoplasm in the substance of which a nucleus was situated. He regarded the protoplasm, as indeed had previously been pointed out by the botanist Unger, as essentially the same as the contractile sarcode which constitutes the body and pseudopodia of the Amœba and other Rhizopoda. As the term "protoplasm," as well as that of "bioplasm" employed by Lionel Beale in a somewhat similar though not precisely identical sense, involves certain theoretical views of the origin and function of the body of the cell, it would be better to apply to it the more purely descriptive term "cytoplasm" or "cell plasm."

Schultze defined protoplasm as a homogeneous, glassy, tenacious material, of a jelly-like or somewhat firmer consistency, in which numerous minute granules were embedded. He regarded it as the part of the cell especially endowed with vital energy, whilst the exact function of the nucleus could not be defined. Based upon this conception of the jelly-like character of protoplasm, the idea for a time prevailed that a structureless, dimly granular, jelly or slime destitute of organisation, possessed great physiological activity, and was the medium through which the phenomena of life were displayed.

More accurate conceptions of the nature of the cell plasm soon began to be entertained. Brücke recognised that the body of the cell was not simple, but had a complex organisation. Flemming observed that the cell plasm contained extremely delicate threads, which frequently formed a network, the interspaces of which were occupied by a more homogeneous substance. Where the threads crossed each other, granular particles (mikrosomen) were situated. Bütschli considered that he could recognise in the cell plasm a honeycomb-like appearance, as if it consisted of excessively minute chambers in which a homogeneous, more or less fluid, material was contained. The polar and spindle-like radiations visible during the process of karyokinesis, which have already been referred to, and the presence of the centrosome, possibly even during the resting stage of the cell, furnished additional illustrations of differentiation within the cell plasm. In many cells there appears also to be a difference in the character of the cell plasm which immediately surrounds the nucleus and that which lies at and near the periphery of the cell. The peripheral part (ektoplasma) is more compact and gives a definite outline to the cell, although not necessarily differentiating into a cell membrane. The inner part (endoplasma) is softer, and is distinguished by a more distinct granular appearance, and by containing the products specially formed in each particular kind of cell during the nutritive process.

By the researches of numerous investigators on the internal organisation of cells in plants and animals, a large body of evidence has now been accumulated, which shows that both the nucleus and the cell plasm consist of something more than a homogeneous, more or less viscid, slimy material. Recognisable objects in the form of granules, threads or fibres can be distinguished in each. The cell plasm and the nucleus respectively are therefore not of the same constitution throughout, but possess polymorphic characters, the study of which in health and the changes produced by disease will for many years to come form important matters for investigation.

### *Function of Cells.*

It has already been stated that, when new cells arise within pre-existing cells, division of the nucleus is associated with cleavage of the cell plasm, so that it participates in the process of new cell-formation. Undoubtedly, however, its *rôle* is not limited to this function. It also plays an important part in secretion, nutrition, and the special functions discharged by the cells in the tissues and organs of which they form morphological elements.

Between 1838 and 1842 observations were made which showed that cells were constituent parts of secreting glands and mucous membranes (Schwann, Henle). In 1842 John Goodsir communicated to the Royal Society of Edinburgh a memoir on secreting structures, in which he established the principle that cells are the ultimate secreting agents; he recognised in the cells of the liver, kidney, and other organs the characteristic secretion of each gland. The secretion was, he said, situated between the nucleus and the cell wall. At first he thought that, as the nucleus was the reproductive organ of the cell, the secretion was formed in the interior of the cell by the agency of the cell wall; but three years later he regarded it as a product of the nucleus. The study of the process of spermatogenesis by his brother, Harry Goodsir, in which the head of the spermatozoon was found to correspond with the nucleus of the cell in which the spermatozoon arose, gave support to the view that the nucleus played an important part in the genesis of the characteristic product of the gland cell.

The physiological activity of the cell plasm and its complex chemical constitution soon after began to be recognised. Some years before Max Schultze had published his memoirs on the characters of protoplasm, Brücke had shown that the well-known changes in tint in the skin of the Chamæleon were due to pigment granules situated in the cells in the skin which were sometimes diffused throughout the cells, at others concentrated in the centre. Similar observations on the skin of the frog were made in 1854 by von Wittich and Harless. The movements were regarded as due to contraction of the cell wall on its contents. In a most interesting paper on the pigmentary system in the frog, published in 1858, Lord Lister demonstrated that the pigment granules moved in the cell plasma, by forces resident within the cell itself, acting under the influence of an external stimulant, and not by contractility of the wall. Under some conditions the pigment was attracted to the centre of the cell, when the skin became pale; under other conditions the pigment was diffused throughout the body and the branches of the cell, and gave to the skin a dark colour. It was also experimentally shown that a potent influence over these movements was exercised by the nervous system.

The study of the cells of glands engaged in secretion, even when the secretion is colourless, and the comparison of their appearance when secretion is going on with that seen when the cells are at rest, have shown that the cell plasm is much more granular and opaque, and contains larger particles during activity than when the cell is passive; the body of the cell swells out from an increase in the contents of its plasm, and chemical changes accompany the act of secretion. Ample evidence, therefore, is at hand to support the position taken by John Goodsir, nearly sixty years ago, that secretions are formed within cells, and lie in that part of the cell which we now say consists of the cell plasm; that each secreting cell is endowed with its own peculiar property, according to the organ in which it is situated, so that bile is formed by the cells in the liver, milk by those in the mamma, and so on.

Intimately associated with the process of secretion is that of nutrition. As the cell plasm lies at the periphery of a cell, and as it is, alike both in secretion and nutrition, brought into closest relation with the surrounding medium, from which the pabulum is derived, it is necessarily associated with the nutritive activity. Its position enables it to absorb nutritive material directly from without, and in the process of growth it increases in amount by interstitial changes and additions throughout its substance, and not by mere accretions on its surface.

Hitherto I have spoken of a cell as a unit, independent of its neighbours as regards its nutrition and the other functions which it has to discharge. The question has, however, been discussed, whether in a tissue composed of cells closely packed together cell plasm may not give origin to processes or threads which are in contact or continuous with corresponding processes of adjoining cells, and that cells may therefore, to some extent, lose their individuality in the colony of which they are members. Appearances were recognised between 1863 and 1870 by Schrön and others in the deeper cells of the epidermis and of some mucous membranes which gave sanction to this view, and it seems possible through contact or continuity of threads connecting a cell with its neighbours, that cells may exercise a direct influence on each other.

Nägeli, the botanist, as the foundation of a mechanico-physiological theory of descent, considered that in plants a network of cell plasm, named by him idio-plasm, extended throughout the whole of the plant, forming its specific molecular constitution, and that growth and activity were regulated by its conditions of tension and movements (1884).

The study of the structure of plants with special reference to the presence of an intercellular network has for some years been pursued by Walter Gardiner (1882–97), who has demonstrated threads of cell plasm protruding through the walls of vegetable cells and continuous with similar threads from adjoining cells. Structurally, therefore, a plant may be conceived to be built up of a nucleated cytoplasmic network, each nucleus with the branching cell plasm surrounding it being a centre of activity. On this view a cell would retain to some extent its individuality, though, as Gardiner contends, the connecting threads would be the medium for the conduction of impulses and of food from a cell to those which lie around it. For the plant cell therefore, as has long been accepted in the animal cell, the wall is reduced to a secondary position, and the active constituent is the nucleated cell plasm. It is not unlikely that the absence of a controlling nervous system in plants requires the plasm of adjoining cells to be brought into more immediate contact and continuity than is the case with the generality of animal cells, so as to provide a mechanism for harmonising the nutritive and other functional processes in the different areas in the body of the plant. In this particular, it is of interest to note that the epithelial tissues in animals, where somewhat similar connecting arrangements occur, are only indirectly associated with the nervous and vascular systems, so that, as in plants, the cells may require, for nutritive and other purposes, to act and react directly on each other.

### *Nerve Cells.*

Of recent years great attention has been paid to the intimate structure of nerve cells, and to the appearance which they present when in the exercise of their functional activity. A nerve cell is not a secreting cell; that is, it does not derive from the blood or surrounding fluid a pabulum which it elaborates into a visible, palpable secretion characteristic of the organ of which the cell is a constituent element, to be in due course discharged into a duct which conveys the secretion out of the gland. Nerve cells, through the metabolic changes which take place in them in connection with their nutrition, are associated with the production of the form of energy specially exhibited by animals which possess a nervous system, termed nerve energy. It has long been known that every nerve cell has a body in which a relatively large nucleus is situated. A most important discovery was the recognition that the body of every nerve cell had one or more processes growing out from it. More recently it has been proved, chiefly through the researches of Schultze, His, Golgi and Ramon y Cajal, that at least one of the processes, the axon of the nerve cell, is continued into the axial cylinder of a nerve fibre, and that in the multipolar nerve cell the other processes, or dendrites, branch and ramify for some distance away from the body. A nerve fibre is therefore an essential part of the cell with which it is continuous, and the cell, its processes, the nerve fibre and the collaterals which arise from the nerve fibre collectively form a neuron or structural nerve unit (Waldeyer). The nucleated body of the nerve cell is the physiological centre of the unit.

The cell plasm occupies both the body of the nerve cell and its processes. The intimate structure of the plasm has, by improved methods of observation introduced during the last eight years by Nissl, and conducted on similar lines by other investigators, become more definitely understood. It has been ascertained that it possesses two distinct characters which imply different structures. One of these stains deeply on the addition of certain dyes, and is named chromophile or chromatic substance; the other, which does not possess a similar property, is the achromatic network. The chromophile is found in the cell body and the dendritic processes, but not in the axon. It occurs in the form of granular particles, which may be scattered throughout the plasm, or aggregated into little heaps which are elongated or fusiform in shape and appear as distinct coloured particles or masses. The achromatic network is found in the cell body and the dendrites, and is continued also into the axon, where it forms the axial cylinder of the nerve fibre. It consists apparently of delicate threads or fibrillæ, in the meshes of which a homogeneous material, such as is found in the cell plasm generally, is contained. In the nerve cells, as in other cells, the plasm is without doubt concerned in the process of cell nutrition. The achromatic fibrillæ exercise an important influence on the axon or nerve fibre with which they are continuous, and probably they conduct the nerve impulses which manifest themselves in the form of nerve energy. The dendritic processes of a multipolar nerve cell ramify in close relation with similar processes branching from other cells in the same group. The collaterals and the free end of the axon fibre process branch and ramify in association with the body of a nerve cell or of its dendrites. We cannot say that these parts are directly continuous with each other to form an intercellular network, but they are apparently in apposition, and through contact exercise influence one on the other in the transmission of nerve impulses.

There is evidence to show that in the nerve cell the nucleus, as well as the cell plasm, is an effective agent in nutrition. When the cell is functionally active, both the cell body and the nucleus increase in size (Vas, G. Mann, Lugaro); on the other hand, when nerve cells are fatigued through excessive use, the nucleus decreases in size and shrivels; the cell plasm also shrinks, and its coloured or chromophile constituent becomes diminished in quantity, as if it had been consumed during the prolonged use of the cell (Hodge, Mann, Lugaro). It is interesting also to note that in hibernating animals in the winter season, when their functional activity is reduced to a minimum, the chromophile in the plasm of the nerve cells is much smaller in amount than when the animal is leading an active life in the spring and summer (G. Levi).

When a nerve cell has attained its normal size it does not seem to be capable of reproducing new cells in its substance by a process of karyokinesis, such as takes place when young cells arise in the egg and in the tissues generally. It would appear that nerve cells are so highly specialised in their association with the evolution of nerve energy, that they have ceased to have the power of reproducing their kind, and the metabolic changes both in cell plasm and nucleus are needed to enable them to discharge their very peculiar function. Hence it follows that when a portion of the brain or other nerve-centre is destroyed, the injury is not repaired by the production of fresh specimens of their characteristic cells, as would be the case in injuries to bones and tendons.

In our endeavours to differentiate the function of the nucleus from that of the cell plasm, we should not regard the former as concerned only in the production of young cells, and the latter as the exclusive agent in growth, nutrition, and, where gland cells are concerned, in the formation of their characteristic products. As regards cell reproduction also, though the process of division begins in the nucleus in its chromosome constituents, the achromatic figure in the cell plasm undoubtedly plays a part, and the cell plasm itself ultimately undergoes cleavage.

A few years ago the tendency amongst biologists was to ignore or attach but little importance to the physiological use of the nucleus in the nucleated cell, and to regard the protoplasm as the essential and active constituent of living matter; so much so, indeed, was this the case that independent organisms regarded as distinct species were described as consisting of protoplasm destitute of a nucleus; also that scraps of protoplasm separated from larger nucleated masses could, when isolated, exhibit vital phenomena. There is reason to believe that a fragment of protoplasm, when isolated from the nucleus of a cell, though retaining its contractility and capable of nourishing itself for a short time, cannot increase in amount, act as a secreting structure, or reproduce its kind: it soon loses its activity, withers, and dies. In order that these qualities of living matter should be retained, a nucleus is by most observers regarded as necessary (Nussbaum, Gruber, Haberlandt, Korschelt), and for the complete manifestation of vital activity both nucleus and cell plasm are required.

### *Bacteria.*

The observations of Cohn, made about thirty years ago, and those of De Bary shortly afterwards, brought into notice a group of organisms to which the name "bacterium" or "microbe" is given. They were seen to vary in shape: some were rounded specks called cocci, others were straight rods called bacilli, others were curved or spiral rods, vibrios or spirillæ. All were characterised by their extreme minuteness, and required for their examination the highest powers of the best microscopes. Many bacteria measure in their least diameter not more than 1/25000th of an inch, 1/10th the diameter of a human white blood corpuscle. Through the researches of Pasteur, Lord Lister, Koch, and other observers, bacteria have been shown to play an important part in nature. They exercise a very remarkable power over organic substances, especially those which are complex in chemical constitution, and can resolve them into simpler combinations. Owing to this property, some bacteria are of great economic value, and without their agency many of our industries could not be pursued; others again, and these are the most talked of, exercise a malign influence in the production of the most deadly diseases which afflict man and the domestic animals.

Great attention has been given to the structure of bacteria and to their mode of propagation. When examined in the living state and magnified about 2000 times, a bacterium appears as a homogeneous particle, with a sharp definite outline, though a membranous envelope or wall, distinct from the body of the bacterium, cannot at first be recognised; but when treated with reagents a membranous envelope appears, the presence of which, without doubt, gives precision of form to the bacterium. The substance within the membrane contains granules which can be dyed with colouring agents. Owing to their extreme minuteness it is difficult to pronounce an opinion on the nature of the chromatine granules and the substance in which they lie. Some observers regard them as nuclear material, invested by only a thin layer of protoplasm, on which view a bacterium would be a nucleated cell. Others consider the bacterium as formed of protoplasm containing granules capable of being coloured, which are a part of the protoplasm itself, and not a nuclear substance. On the latter view, bacteria would consist of cell plasm inclosed in a membrane and destitute of a nucleus. Whatever be the nature of the granule-containing material, each bacterium is regarded as a cell, the minutest and simplest living particle capable of an independent existence that has not yet been discovered.

Bacteria cells, like cells generally, can reproduce their kind. They multiply by simple fission, probably with an ingrowth of the cell wall, but without the karyokinetic phenomena observed in nucleated cells. Each cell gives rise to two daughter cells, which may for a time remain attached to each other and form a cluster or a chain, or they may separate and become independent isolated cells. The multiplication, under favourable conditions of light, air, temperature, moisture and food, goes on with extraordinary rapidity, so that in a few hours many thousand new individuals may arise from a parent bacterium.

Connected with the life-history of a bacterium cell is the formation in its substance, in many species and under certain conditions, of a highly refractile shiny particle called a spore. At first sight a spore seems as if it were the nucleus of the bacterium cell, but it is not always present when multiplication by cleavage is taking place, and when present it does not appear to take part in the fission. On the other hand, a spore, from the character of its envelope, possesses great power of resistance, so that dried bacteria, when placed in conditions favourable to germination, can through their spores germinate and resume an active existence. Spore formation seems, therefore, to be a provision for continuing the life of the bacterium under conditions which, if spores had not formed, would have been the cause of its death.

The time has gone by to search for the origin of living organisms by a spontaneous aggregation of molecules in vegetable or other infusions, or from a layer of formless primordial slime diffused over the bed of the ocean. Living matter during our epoch has been, and continues to be, derived from pre-existing living matter, even when it possesses the simplicity of structure of a bacterium, and the morphological unit is the cell.

### *Development of the Egg.*

As the future of the entire organism lies in the fertilised egg cell, we may now briefly review the arrangements, consequent on the process of segmentation, which lead to the formation, let us say in the egg of a bird, of the embryo of the young chick.

In the latter part of the last century, C. F. Wolff observed that the beginning of the embryo was associated with the formation of layers, and in 1817 Pander demonstrated that in the hen's egg at first one layer, called mucous, appeared, then a second or serous layer, to be followed by a third, intermediate or vascular layer. In 1828 von Baer amplified our knowledge in his famous treatise, which from its grasp of the subject created a new epoch in the science of embryology. It was not, however, until the discovery by Schwann of cells as constant factors in the structure of animals and in their relation to development that the true nature of these layers was determined. We now know that each layer consists of cells, and that all the tissues and organs of the body are derived from them. Numerous observers have devoted themselves for many years to the study of each layer, with the view of determining the part which it takes in the formation of the constituent parts of the body, more especially in the higher animals, and the important conclusion has been arrived at that each kind of tissue invariably arises from one of these layers and from no other.

The layer of cells which contributes, both as regards the number and variety of the tissues derived from it, most largely to the formation of the body is the middle layer or mesoblast. From it the skeleton, the muscles, and other locomotor organs, the true skin, the vascular system, including the blood and other structures which I need not detail, take their rise. From the inner layer of cells or hypoblast, the principal derivatives are the epithelial lining of the alimentary canal and of the glands which open into it, and the epithelial lining of the air-passages. The outer or epiblast layer of cells gives origin to the epidermis or scarf skin and to the nervous system. It is interesting to note that from the same layer of the embryo arise parts so different in importance as the cuticle—a mere protecting structure, which is constantly being shed when the skin is subjected to the friction of a towel or the clothes—and the nervous system, including the brain, the most highly differentiated system in the animal body. How completely the cells from which they are derived had diverged from each other in the course of their differentiation in structure and properties is shown by the fact that the cells of the epidermis are continually engaged in reproducing new cells to replace those which are shed, whilst the cells of the nervous system have apparently lost the power of reproducing their kind.

In the early stage of the development of the egg, the cells in a given layer resemble each other in form, and, as far as can be judged from their appearance, are alike in structure and properties. As the development proceeds, the cells begin to show differences in character, and in the course of time the tissues which arise in each layer differentiate from each other and can be readily recognised by the observer. To use the language of von Baer, a generalised structure has become specialised, and each of the special tissues produced exhibits its own structure and properties. These changes are coincident with a rapid multiplication of the cells by cleavage, and thus increase in size of the embryo accompanies specialisation of structure. As the process continues, the embryo gradually assumes the shape characteristic of the species to which its parents belonged, until at length it is fit to be born and to assume a separate existence.

The conversion of cells, at first uniform in character, into tissues of a diverse kind is due to forces inherent in the cells in each layer. The cell plasm plays an active though not an exclusive part in the specialisation; for as the nucleus influences nutrition and secretion, it acts as a factor in the differentiation of the tissues. When tissues so diverse in character as muscular fibre, cartilage, fibrous tissues, and bone arise from the cells of the middle or mesoblast layer, it is obvious that, in addition to the morphological differentiation affecting form and structure, a chemical differentiation affecting composition also occurs, as the result of which a physiological differentiation takes place. The tissues and organs become fitted to transform the energy derived from the food into muscular energy, nerve energy, and other forms of vital activity. Corresponding differentiations also modify the cells of the outer and inner layers. Hence the study of the development of the generalised cell layers in the young embryo enables us to realise how all the complex constituent parts of the body in the higher animals and in man are evolved by the process of differentiation from a simple nucleated cell—the fertilised ovum. A knowledge of the cell and of its life-history is therefore the foundation-stone on which biological science in all its departments is based.

If we are to understand by an organ in the biological sense a complex body capable of carrying on a natural process, a nucleated cell is an organ in its simplest form. In a unicellular animal or plant such an organ exists in its most primitive stage. The higher plants and animals again are built up of multitudes of these organs, each of which, whilst having its independent life, is associated with the others, so that the whole may act in unison for a common purpose. As in one of your great factories each spindle is engaged in twisting and winding its own thread, it is at the same time intimately associated with the hundreds of other spindles in its immediate proximity, in the manufacture of the yarn from which the web of cloth is ultimately to be woven.

It has taken more than fifty years of hard and continuous work to bring our knowledge of the structure and development of the tissues and organs of plants and animals up to the level of the present day. Amidst the host of names of investigators, both at home and abroad, who have contributed to its progress, it may seem invidious to particularise individuals. There are, however, a few that I cannot forbear to mention, whose claim to be named on such an occasion as this will be generally conceded.

Botanists will, I think, acknowledge Wilhelm Hofmeister as a master in morphology and embryology, Julius von Sachs as the most important investigator in vegetable physiology during the last quarter of a century, and Strasburger as a leader in the study of the phenomena of nuclear division.

The researches of the veteran Professor of Anatomy in Würzburg, Albert von Kölliker, have covered the entire field of animal histology. His first paper, published fifty-nine years ago, was followed by a succession of memoirs and books on human and comparative histology and embryology, and culminated in his great treatise on the structure of the brain, published in 1896. Notwithstanding the weight of more than eighty years, he continues to prosecute histological research, and has published the results of his latest, though let us hope not his last, work during the present year.

Amongst our own countrymen, and belonging to the generation which has almost passed away, was William Bowman. His investigations between 1840 and 1850 on the mucous membranes, muscular fibre, and the structure of the kidney, together with his researches on the organs of sense, were characterised by a power of observation and of interpreting difficult and complicated appearances which has made his memoirs on these subjects landmarks in the history of histological inquiry.

Of the younger generation of biologists, Francis Maitland Balfour, whose early death is deeply deplored as a loss to British science, was one of the most distinguished. His powers of observation and philosophic perception gave him a high place as an original inquirer, and the charm of his personality—for charm is not the exclusive possession of the fairer sex—endeared him to his friends.

### *General Morphology.*

Along with the study of the origin and structure of the tissues of organised bodies, much attention has been given during the century to the parts or organs in plants and animals, with the view of determining where and how they take their rise, the order of their formation, the changes which they pass through in the early stages of development, and their relative positions in the organism to which they belong. Investigations on these lines are spoken of as morphological, and are to be distinguished from the study of their physiological or functional relations, though both are necessary for the full comprehension of the living organism.

The first to recognise that morphological relations might exist between the organs of a plant, dissimilar as regards their function, was the poet Goethe, whose observations, guided by his imaginative faculty, led him to declare that the calyx, corolla, and other parts of a flower, the scales of a bulb, &c., were metamorphosed leaves, a principle generally accepted by botanists, and indeed extended to other parts of a plant, which are referred to certain common morphological forms although they exercise different functions. Goethe also applied the same principle in the study of the skeletons of vertebrate animals, and he formed the opinion that the spinal column and the skull were essentially alike in construction, and consisted of vertebræ, an idea which was also independently conceived and advocated by Oken.

The anatomist who in our country most strenuously applied himself to the morphological study of the skeleton was Richard Owen, whose knowledge of animal structure, based upon his own dissections, was unrivalled in range and variety. He elaborated the conception of an ideal, archetype vertebrate form which had no existence in nature, and to which, subject to modifications in various directions, he considered all vertebrate skeletons might be referred. Owen's observations were conducted to a large extent on the skeletons of adult animals, of the knowledge of which he was a master. As in the course of development modifications in shape and in the relative position of parts not unfrequently occur and their original character and place of origin become obscured, it is difficult, from the study only of adults, to arrive at a correct interpretation of their morphological significance. When the changes which take place in the skull during its development, as worked out by Reichert and Rathke, became known and their value had become appreciated, many of the conclusions arrived at by Owen were challenged and ceased to be accepted. It is, however, due to that eminent anatomist to state from my personal knowledge of the condition of anatomical science in this country fifty years ago, that an enormous impulse was given to the study of comparative morphology by his writings, and by the criticisms to which they were subjected.

There can be no doubt that generalised arrangements do exist in the early embryo which, up to a certain stage, are common to animals that in their adult condition present diverse characters, and out of which the forms special to different groups are evolved. As an illustration of this principle, I may refer to the stages of development of the great arteries in the bodies of vertebrate animals. Originally, as the observations of Rathke have taught us, the main arteries are represented by pairs of symmetrically arranged vascular arches, some of which enlarge and constitute the permanent arteries in the adult, whilst others disappear. The increase in size of some of these arches, and the atrophy of others, are so constant for different groups that they constitute anatomical features as distinctive as the modifications in the skeleton itself. Thus in mammals the fourth vascular arch on the left side persists, and forms the arch of the aorta; in birds the corresponding part of the aorta is an enlargement of the fourth right arch, and in reptiles both arches persist to form the great artery. That this original symmetry exists also in man we know from the fact that now and again his body, instead of corresponding with the mammalian type, has an aortic arch like that which is natural to the bird, and in rarer cases even to the reptile. A type form common to the vertebrata does therefore in such cases exist, capable of evolution in more than one direction.

The reputation of Thomas Henry Huxley as a philosophic comparative anatomist rests largely on his early perception of, and insistence on, the necessity of testing morphological conclusions by a reference to the development of parts and organs, and by applying this principle in his own investigations. The principle is now so generally accepted by both botanists and anatomists that morphological definitions are regarded as depending essentially on the successive phases of the development of the parts under consideration.

The morphological characters exhibited by a plant or animal tend to be hereditarily transmitted from parents to offspring, and the species is perpetuated. In each species the evolution of an individual, through the developmental changes in the egg, follows the same lines in all the individuals of the same species, which possess therefore in common the features called specific characters. The transmission of these characters is due, according to the theory of Weismann, to certain properties possessed by the chromosome constituents of the segmentation nucleus in the fertilised ovum, named by him the germ plasm, which is continued from one generation to another, and impresses its specific character on the egg and on the plant or animal developed from it.

As has already been stated, the special tissues which build up the bodies of the more complex organisms are evolved out of cells which are at first simple in form and appearance. During the evolution of the individual, cells become modified or differentiated in structure and function, and so long as the differentiation follows certain prescribed lines the morphological characters of the species are preserved. We can readily conceive that, as the process of specialisation is going on, modifications or variations in groups of cells and the tissues derived from them, notwithstanding the influence of heredity, may in an individual diverge so far from that which is characteristic of the species as to assume the arrangements found in another species, or even in another order. Anatomists had indeed long recognised that variations from the customary arrangement of parts occasionally appeared, and they described such deviations from the current descriptions as irregularities.

### *Darwinian Theory.*

The signification of the variations which arise in plants and animals had not been apprehended until a flood of light was thrown on the entire subject by the genius of Charles Darwin, who formulated the wide-reaching theory that variations could be transmitted by heredity to younger generations. In this manner he conceived new characters would arise, accumulate, and be perpetuated, which would in the course of time assume specific importance. New species might thus be evolved out of organisms originally distinct from them, and their specific characters would in turn be transmitted to their descendants. By a continuance of this process new species would multiply in many directions, until at length from one or more originally simple forms the earth would become peopled by the infinite varieties of plant and animal organisms which have in past ages inhabited, or do at present inhabit, our globe. The Darwinian theory may therefore be defined as Heredity modified and influenced by Variability. It assumes that there is an heredity quality in the egg, which, if we take the common fowl for an example, shall continue to produce similar fowls. Under conditions, of which we are ignorant, which occasion molecular changes in the cells and tissues of the developing egg, variations might arise in the first instance probably slight, but becoming intensified in successive generations, until at length the descendants would have lost the characters of the fowl and have become another species. No precise estimate has been arrived at, and indeed one does not see how it is possible to obtain it, of the length of years which might be required to convert a variation, capable of being transmitted, into a new and definite specific character.

The circumstances which, according to the Darwinian theory, determined the perpetuation by hereditary transmission of a variety and its assumption of a specific character depended, it was argued, on whether it possessed such properties as enabled the plant or animal in which it appeared to adapt itself more readily to its environment, *i.e.* to the surrounding conditions. If it were to be of use the organism in so far became better adapted to hold its own in the struggle for existence with its fellows and with the forces of nature operating on it. Through the accumulation of useful characters the specific variety was perpetuated by natural selection, so long as the conditions were favourable for its existence, and it survived as being the best fitted to live. In the study of the transmission of variations which may arise in the course of development it should not be too exclusively thought that only those variations are likely to be preserved which can be of service during the life of the individual, or in the perpetuation of the species, and possibly available for the evolution of new species. It should also be kept in mind that morphological characters can be transmitted by hereditary descent, which, though doubtless of service in some bygone ancestor, are in the new conditions of life of the species of no physiological value. Our knowledge of the structural and functional modifications to be found in the human body, in connection with abnormalities and with tendencies or predisposition to diseases of various kinds, teaches us that characters which are of no use, and indeed detrimental to the individual, may be hereditarily transmitted from parents to offspring through a succession of generations.

Since the conception of the possibility of the evolution of new species from pre-existing forms took possession of the minds of naturalists, attempts have been made to trace out the lines on which it has proceeded. The first to give a systematic account of what he conceived to be the order of succession in the evolution of animals was Ernst Haeckel, of Jena, in a well-known treatise. Memoirs on special departments of the subject, too numerous to particularise, have subsequently appeared. The problem has been attacked along two different lines: the one by embryologists, of whom may be named Kowalewsky, Gegenbaur, Dohrn, Ray Lankester, Balfour and Gaskell, who with many others have conducted careful and methodical inquiries into the stages of development of numerous forms belonging to the two great divisions of the animal kingdom. Invertebrates, as well as vertebrates, have been carefully compared with each other in the bearing of their development and structure on their affinities and descent, and the possible sequence in the evolution of the Vertebrata from the Invertebrata has been discussed. The other method pursued by palæontologists, of whom Huxley, Marsh, Cope, Osborne and Traquair are prominent authorities, has been the study of the extinct forms preserved in the rocks and the comparison of their structure with each other and with that of existing organisms. In the attempts to trace the line of descent the imagination has not unfrequently been called into play in constructing various conflicting hypotheses. Though from the nature of things the order of descent is, and without doubt will continue to be, ever a matter of speculation and not of demonstration, the study of the subject has been a valuable intellectual exercise and a powerful stimulant to research.

We know not as regards time when the fiat went forth, "Let there be Life, and there was Life." All we can say is that it must have been in the far-distant past, at a period so remote from the present that the mind fails to grasp the duration of the interval. Prior to its genesis our earth consisted of barren rock and desolate ocean. When matter became endowed with Life, with the capacity of self-maintenance and of resisting external disintegrating forces, the face of nature began to undergo a momentous change. Living organisms multiplied, the land became covered with vegetation, and multitudinous varieties of plants, from the humble fungus and moss to the stately palm and oak, beautified its surface and fitted it to sustain higher kinds of living beings. Animal forms appeared, in the first instance simple in structure, to be followed by others more complex, until the mammalian type was produced. The ocean also became peopled with plant and animal organisms, from the microscopic diatom to the huge leviathan. Plants and animals acted and reacted on each other, on the atmosphere which surrounded them and on the earth on which they dwelt, the surface of which became modified in character and aspect. At last Man came into existence. His nerve-energy, in addition to regulating the processes in his economy which he possesses in common with animals, was endowed with higher powers. When translated into psychical activity it has enabled him throughout the ages to progress from the condition of a rude savage to an advanced stage of civilisation; to produce works in literature, art, and the moral sciences which have exerted, and must continue to exert, a lasting influence on the development of his higher Being; to make discoveries in physical science; to acquire a knowledge of the structure of the earth, of the ocean in its changing aspects, of the atmosphere and the stellar universe, of the chemical composition and physical properties of matter in its various forms, and to analyse, comprehend, and subdue the forces of nature.

By the application of these discoveries to his own purposes Man has, to a large extent, overcome time and space; he has studded the ocean with steamships, girdled the earth with electric wire, tunnelled the lofty Alps, spanned the Forth with a bridge of steel, invented machines and founded industries of all kinds for the promotion of his material welfare, elaborated systems of government fitted for the management of great communities, formulated economic principles, obtained an insight into the laws of health, the causes of infective diseases, and the means of controlling and preventing them.

When we reflect that many of the most important discoveries in abstract science and in its applications have been made during the present century, and indeed since the British Association held its first meeting in the ancient capital of your county sixty-nine years ago, we may look forward with confidence to the future. Every advance in science provides a fresh platform from which a new start can be made. The human intellect is still in process of evolution. The power of application and of concentration of thought for the elucidation of scientific problems is by no means exhausted. In science is no hereditary aristocracy. The army of workers is recruited from all classes. The natural ambition of even the private in the ranks to maintain and increase the reputation of the branch of knowledge which he cultivates affords an ample guarantee that the march of science is ever onwards, and justifies us in proclaiming for the next century, as in the one fast ebbing to a close, that Great is Science, and it will prevail.

## SECTION A.

### MATHEMATICS AND PHYSICS.

OPENING ADDRESS BY JOSEPH LARMOR, M.A., D.SC., F.R.S., PRES. C.P.S., PRESIDENT OF THE SECTION.

IT is fitting that before entering upon the business of the Section we should pause to take note of the losses which our department of science has recently sustained. The fame of Bertrand, apart from his official position as Secretary of the French Academy of Sciences, was long ago universally established by his classical treatise on the Infinitesimal Calculus: it has been of late years sustained by the luminous exposition and searching criticism of his books on the Theory of Probability and Thermodynamics and Electricity. The debt which we owe to that other veteran, G. Wiedemann, both on account of his own researches, which take us back to the modern revival of experimental physics, and for his great and indispensable thesaurus of the science of electricity, cannot easily be overstated. By the death of Sophus Lie, following soon after his return to a chair in his native country Norway, we have lost one of the great constructive mathematicians of the century, who has in various directions fundamentally expanded the methods and conceptions of analysis by reverting to the fountain of direct geometrical intuition. In Italy the death of Beltrami has removed an investigator whose influence has been equally marked on the theories of transcendental geometry and on the progress of mathematical physics. In our own country we have lost in D. E. Hughes one of the great scientific inventors of the age; while we specially deplore the removal, in his early prime, of one who has recently been well known at these meetings, Thomas Preston, whose experimental investigations on the relations between magnetism and light, combined with his great powers of lucid exposition, marked out for him a brilliant future.

Perhaps the most important event of general scientific interest during the past year has been the definite undertaking of the great task of the international co-ordination of scientific literature; and it may be in some measure in the prolonged conferences that were necessitated by that object that the recently announced international federation of scientific academies has had its origin. In the important task of rendering accessible the stores of scientific knowledge, the British Association, and in particular this Section of it, has played the part of pioneer. Our annual volumes have long been classical, through the splendid reports of the progress of the different branches of knowledge that have been from time to time contributed to them by the foremost British men of science; and our work in this direction has received the compliment of successful imitation by the sister Associations on the Continent.

The usual conferences connected with our department of scientific activity have been this year notably augmented by the very successful international congresses of mathematicians and of physicists which met a few weeks ago in Paris. The three volumes of reports on the progress of physical science during the last ten years, for which we are indebted to the initiative of the French Physical Society, will provide an admirable conspectus of the present trend of activity, and form a permanent record for the history of our subject.

Another very powerful auxiliary to progress is now being rapidly provided by the republication, in suitable form and within reasonable time, of the collected works of the masters of our science. We have quite recently received, in a large quarto volume, the mass of most important unpublished work that was left behind him by the late Prof. J. C. Adams; the zealous care of Prof. Sampson has worked up into order the more purely astronomical part of the volume; while the great undertaking, spread over many years, of the complete determination of the secular change of the magnetic condition of the earth, for which the practical preparations had been set on foot by Gauss himself, has been prepared for the press by Prof. W. G. Adams. By the publication of the first volume of Lord Rayleigh's papers a series of memoirs which have formed a main stimulus to the progress of mathematical physics in this country during the past twenty years has become generally accessible. The completed series will form a landmark for the end of the century that may be compared with Young's "Lectures on Natural Philosophy" for its beginning.

The recent reconstruction of the University of London, and the foundation of the University of Birmingham, will, it is to be hoped, give greater freedom to the work of our University Colleges. The system of examinations has formed an admirable stimulus to the effective acquisition of that general knowledge which is a necessary part of all education. So long as the examiner recognises that his function is a responsible and influential one, which is to be taken seriously from the point of view of moulding the teaching in places where external guidance is helpful, test by examination will remain a most valuable means of extending the area of higher education. Except for workers in rapidly progressive branches of technical science, a broad education seems better adapted to the purposes of life than special training over a narrow range; and it is difficult to see how a reasonably elastic examination test can be considered as a hardship. But the case is changed when preparation for a specialised scientific profession, or mastery of the lines of attack in an unsolved problem, is the object. The general education has then been presumably finished; in expanding departments of knowledge, variety rather than uniformity of training should be the aim, and the genius of a great teacher should be allowed free play without external trammels. It would appear that in this country we have recently been liable to unduly mix up two methods. We have been starting students on the special and lengthy, though very instructive, processes which are known as original research at an age when their time would be more profitably employed in rapidly acquiring a broad basis of knowledge. As a result, we have been extending the examination test from the general knowledge to which it is admirably suited into the specialised activity which is best left to the stimulus of personal interest. Informal contact with competent advisers, themselves imbued with the scientific spirit, who can point the way towards direct appreciation of the works of the masters of the science, is far more effective than detailed instruction at second hand, as regards growing subjects that have not yet taken on an authoritative form of exposition. Fortunately there seems to be now no lack of such teachers to meet the requirements of the technical colleges that are being established throughout the country.

The famous treatise which opened the modern era by treating magnetism and electricity on a scientific basis appeared just 300 years ago. The author, William Gilbert, M.D., of Colchester, passed from the Grammar School of his native town to St. John's College, Cambridge: soon after taking his first degree, in 1560, he became a Fellow of the College, and seems to have remained in residence, and taken part in its affairs, for about ten years. All through his subsequent career, both at Colchester and afterwards at London, where he attained the highest position in his profession, he was an exact and diligent explorer, first of chemical and then of magnetic and electric phenomena. In the words of the historian Hallam, writing in 1839, "in his Latin treatise on the Magnet he not only collected all the knowledge which others had possessed, but he became at once the father of experimental philosophy in this island"; and no demur would be raised if Hallam's restriction to this country were removed. Working nearly a century before the time when the astronomical discoveries of Newton had originated the idea of attraction at a distance, he established a complete formulation of the interaction of magnets by what we now call the exploration of their fields of force. His analysis of the facts of magnetic influence, and incidentally of the points in which it differs from electric influence, is virtually the one which Faraday re-introduced. A cardinal advance was achieved, at a time when the Copernican Astronomy had still largely to make its way, by assigning the behaviour of the compass and the dip needle to the fact that the earth itself is a great magnet, by whose field of influence they are controlled. His book passed through many editions on the Continent within forty years; it won the high praise of Galileo. Gilbert has been called "the father of modern electricity" by Priestley, and "the Galileo of magnetism" by Poggendorff.

When the British Association last met at Bradford in 1873 the modern theory which largely reverts to Gilbert's way of formulation, and refers electric and magnetic phenomena to the activity of the æther instead of attractions at a distance, was of recent growth; it had received its classical exposition only two years before by the publication of Clerk Maxwell's treatise. The new doctrine was already widely received in England on its own independent merits. On the Continent it was engaging the strenuous attention of Helmholtz, whose series of memoirs, deeply probing the new ideas in their relation to the prevalent and fairly successful theories of direct action across space, had begun to appear in 1870. During many years the search for crucial experiments that would go beyond the results equally explained by both views met with small success; it was not until 1887 that Hertz, by the discovery of the æthereal radiation of long wave-length emitted from electric oscillators, verified the hypothesis of Faraday and Maxwell and initiated a new era in the practical development of physical science. The experimental field thus opened up was soon fully occupied both in this country and abroad; and the borderland between the sciences of optics and electricity is now being rapidly explored. The extension of experimental knowledge was simultaneous with increased attention to directness of explanation; the expositions of Heaviside and Hertz and other writers fixed attention, in a manner already briefly exemplified by Maxwell himself, on the inherent simplicity of the completed æthereal scheme, when once the theoretical scaffolding employed in its construction and dynamical consolidation is removed; while Poynting's beautiful corollary specifying the path of the transmission of energy through the æther has brought the theory into simple relations with the applications of electrodynamics.

Equally striking has been the great mastery obtained during the last twenty years over the practical manipulation of electric power. The installation of electric wires as the nerves connecting different regions of the earth had attained the rank of accomplished fact so long ago as 1857, when the first Atlantic cable was laid. It was largely the theoretical and practical difficulties, many of them unforeseen, encountered in carrying that great undertaking to a successful issue, that necessitated the elaboration by Lord Kelvin and his coadjutors of convenient methods and instruments for the exact measurement of electric quantities, and thus prepared the foundation for the more recent practical developments in other directions. On the other hand, the methods of theoretical explanation have been in turn improved and simplified through the new ways of considering the phenomena which have been evolved in the course of practical advances on a large scale, such as the improvement of dynamo armatures, the conception and utilisation of magnetic circuits, and the transmission of power by alternating currents. In our time the relations of civilised life have been already perhaps more profoundly altered than ever before, owing to the establishment of practically instantaneous electric communication between all parts of the world. The employment of the same subtle agency is now rapidly superseding the artificial reciprocating engines and other contrivances for the manipulation of mechanical power that were introduced with the employment of steam. The possibilities of transmitting power to great distances at enormous tension, and therefore with very slight waste, along lines merely suspended in the air, are being practically realised; and the advantages thence derived are increased manifold by the almost automatic manner in which the electric power can be transformed into mechanical rotation at the very point where it is desired to apply it. The energy is transmitted at such lightning speed that at a given instant only an exceedingly minute portion of it is in actual transit. When the tension of the alternations is high, the amount of electricity that has to oscillate backwards and forwards on the guiding wires is proportionately diminished, and the frictional waste reduced. At the terminals the direct transmission from one armature of the motor to the other, across the intervening empty space, at once takes us beyond the province of the pushing and rubbing contacts that are unavoidable in mechanical transmission; while the perfect symmetry and reversibility of the arrangement by which power is delivered from a rotatory alternator at one end, guided by the wires to another place many miles away, where it is absorbed by another alternator with precise reversal of the initial stages, makes this process of distribution of energy resemble the automatic operations of nature rather than the imperfect material connections previously in use. We are here dealing primarily with the flawless continuous medium which is the transmitter of radiant energy across the celestial spaces; the part played by the coarsely constituted material conductor is only that of a more or less imperfect guide which directs the current of æthereal energy. The wonderful nature of this theoretically perfect, though of course practically only approximate, method of abolishing limitations of locality with regard to mechanical power is not diminished by the circumstance that its principle must have been in some manner present to the mind of the first person who fully realised the character of the reversibility of a gramme armature.

In theoretical knowledge a new domain, to which the theory as expounded twenty years ago had little to say, has recently been acquired through the experimental scrutiny of the electric discharge in rarefied gaseous media. The very varied electric phenomena of vacuum tubes, whose electrolytic character was first practically established by Schuster, have been largely reduced to order through the employment of the high exhaustions introduced and first utilised by Crookes. Their study under these circumstances, in which the material molecules are so sparsely distributed as but rarely to interfere with each other, has conduced to enlarged knowledge and verification of the fundamental relations in which the individual molecules stand to all electric phenomena, culminating recently in the actual determination, by J. J. Thomson and others following in his track, of the masses and velocities of the particles that carry the electric discharge across the exhausted space. The recent investigations of the circumstances of the electric dissociation produced in the atmosphere and in other gases by ultra-violet light, the Röntgen radiation, and other agencies, constitute one of the most striking developments in experimental molecular physics since Graham determined the molecular relations of gaseous diffusion and transpiration more than half a century ago. This advance in experimental knowledge of molecular phenomena, assisted by the discovery of the precise and rational effect of magnetism on the spectrum, has brought into prominence a modification or rather development of Maxwell's exposition of electric theory, which was dictated primarily by the requirements of the abstract theory itself; the atoms or ions are now definitely introduced as the carriers of those electric charges which interact across the æther, and so produce the electric fields whose transformations were the main subject of the original theory.

We are thus inevitably led, in electric and æthereal theory, as in the chemistry and dynamics of the gaseous state which is the department of abstract physics next in order of simplicity, to the consideration of the individual molecules of matter. The theoretical problems which had come clearly into view a quarter of a century ago, under Maxwell's lead, whether in the exact dynamical relations of æthereal transmission or in the more fortuitous domain of the statistics of interacting molecules, are those around which attention is still mainly concentrated; but as the result of the progress in each, they are now tending towards consolidation into one subject. I propose—leaving further review of the scientific aspect of the recent enormous development of the applications of physical science for hands more competent to deal with the practical side of that subject—to offer some remarks on the scope and validity of this molecular order of ideas, to which the trend of physical explanation and development is now setting in so pronounced a manner.

If it is necessary to offer an apology for detaining the attention of the Section on so abstract a topic, I can plead its intrinsic philosophical importance. The hesitation so long felt on the Continent in regard to discarding the highly-developed theories which analysed all physical actions into direct attractions between the separate elements of the bodies concerned, in favour of a new method in which our ideas are carried into regions deeper than the phenomena, has now given place to eager discussion of the potentialities of the new standpoint. There has even appeared a disposition to consider that the Newtonian dynamical principles, which have formed the basis of physical explanation for nearly two centuries, must be replaced in these deeper subjects by a method of direct description of the mere course of phenomena, apart from any attempt to establish causal relations; the initiation of this method being traced, like that of the Newtonian dynamics itself, to this country. The question has arisen as to how far the new methods of æthereal physics are to be considered as an independent departure, how far they form the natural development of existing dynamical science. In England, whence the innovation came, it is the more conservative position that has all along been occupied. Maxwell was himself trained in the school of physics established in this country by Sir George Stokes and Lord Kelvin, in which the dominating idea has been that of the strictly dynamical foundation of all physical action. Although the pupil's imagination bridged over dynamical chasms, across which the master was not always able to follow, yet the most striking feature of Maxwell's scheme was still the dynamical framework into which it was built. The more advanced reformers have now thrown overboard the apparatus of potential functions which Maxwell found necessary for the dynamical consolidation of his theory, retaining only the final result as a verified descriptive basis for the phenomena. In this way all difficulties relating to dynamical development and indeed consistency are avoided, but the question remains as to how much is thereby lost. In practical electro-magnetics the transmission of power is now the most prominent phenomenon; if formal dynamics is put aside in the general theory, its guidance must here be replaced by some more empirical and tentative method of describing the course of the transmission and transformation of mechanical energy in the system.

The direct recognition in some form, either explicitly or tacitly, of the part played by the æther, has become indispensable to the development and exposition of general physics ever since the discoveries of Hertz left no further room for doubt that this physical scheme of Maxwell was not merely a brilliant speculation, but constituted, in spite of outstanding gaps and difficulties, a real formulation of the underlying unity in physical dynamics. The domain of abstract physics is in fact roughly divisible into two regions. In one of them we are mainly concerned with interactions between one portion of matter and another portion occupying a different position in space; such interactions have very uniform and comparatively simple relations; and the reason is traceable to the simple and uniform constitution of the intervening medium in which they have their seat. The other province is that in which the distribution of the material molecules comes into account. Setting aside the ordinary dynamics of matter in bulk, which is founded on the uniformity of the properties of the bodies concerned and their experimental determination, we must assign to this region all phenomena which are concerned with the unco-ordinated motions of the molecules, including the range of thermal and in part of radiant actions; the only possible basis for detailed theory is the statistical dynamics of the distribution of the molecules. The far more deep-seated and mysterious processes which are involved in changes in the constitution of the individual molecules themselves are mainly outside the province of physics, which is competent to reason only about permanent material systems; they must be left to the sciences of chemistry and physiology. Yet the chemist proclaims that he can determine only the results of his reactions and the physical conditions under which they occur; the character of the bonds which hold atoms in their chemical combinations is at present unknown, although a large domain of very precise knowledge relating, in some diagrammatic manner, to the topography of the more complex molecules has been attained. The vast structure which chemical science has in this way raised on the narrow foundation of the atomic theory is perhaps the most wonderful existing illustration both of the rationality of natural processes and of the analytical powers of the human mind. In a word, the complication of the material world is referable to the vast range of structure and of states of aggregation in the material atoms; while the possibility of a science of physics is largely due to the simplicity of constitution of the universal medium through which the individual atoms interact on each other.

The reference of the uniformity in the interactions at a distance between material bodies to the part played by the æther is a step towards the elimination of extraneous and random hypotheses about laws of attraction between atoms. It also places that medium on a different basis from matter, in that its mode of activity is simple and regular, whereas intimate material interactions must be of illimitable complexity. This gives strong ground for the view that we should not be tempted towards explaining the simple group of relations which have been found to define the activity of the æther, by treating them as mechanical consequences of concealed structure in that medium; we should rather rest satisfied with having attained to their exact dynamical correlation, just as geometry explores or correlates, without explaining, the descriptive and metric properties of space. On the other hand, a view is upheld which considers the pressures and thrusts of the engineer, and the strains and stresses in the material structures by which he transmits them from one place to another, to be the archetype of the processes by which all mechanical effect is transmitted in nature. This doctrine implies an expectation that we may ultimately discover something analogous to structure in the celestial spaces, by means of which the transmission of physical effect will be brought into line with the transmission of mechanical effect by material framework.

At a time when the only definitely ascertained function of the æther was the undulatory propagation of radiant energy across space, Lord Kelvin pointed out that, by reason of the very great velocity of propagation, the density of the radiant energy in the medium at any place must be extremely small in comparison with the amount of energy that is transmitted in a second of time: this easily led him to the very striking conclusion that, on the hypothesis that the æther is like material elastic media, it is not necessary to assume its density to be more than $10^{-18}$ of that of water, or its optical rigidity to be more than ten $10^{-8}$ of that of steel or glass. Thus far the æther would be merely an impalpable material atmosphere for the transference of energy by radiation, at extremely small densities but with very great speed, while ordinary matter would be the seat of practically all this energy. But this way of explaining the absence of sensible influence of the æther on the phenomena of material dynamics lost much of its basis as soon as it was recognised that the same medium must be the receptacle of very high densities of energy in the electric fields around currents and magnets.[1] The other mode of explanation is to consider the æther to be of the very essence of all physical actions, and to correlate the absence of obvious mechanical evidence of its intervention with its regularity and universality.

On this plan of making the æther the essential factor in the transformation of energy as well as its transmission across space, the material atom must be some kind of permanent nucleus that retains around itself an æthereal field of physical influence, such as, for example, a field of strain. We can recognise the atom only through its interactions with other atoms that are so far away from it as to be practically independent systems; thus our direct knowledge of the atom will be confined to this field of force which belongs to it. Just as the exploration of the distant field of magnetic influence of a steel magnet, itself concealed from view, cannot tell us anything about the magnet except the amount and direction of its moment, so a practically complete knowledge of the field of physical influence of an atom might be expressible in terms of the numerical values of a limited number of physical moments associated with it, without any revelation as to its essential structure or constitution being involved. This will at any rate be the case for ultimate atoms if, as is most likely, the distances at which they are kept apart are large compared with the diameters of the atomic nuclei; it in fact forms our only chance for penetrating to definite dynamical views of molecular structure. So long as we cannot isolate a single molecule, but must deal observationally with an innumerable distribution of them, even this kind of knowledge will be largel confined to average values. But the last half-century has witnessed the successful application of a new instrument of research, which has removed in various directions the limitations that had previously been placed on the knowledge to which it was possible for human effort to look forward. The spectroscope has created a new astronomy by revealing the constitutions and the unseen internal motions of the stars. Its power lies in the fact that it does take hold of the internal relations of the individual molecule of matter, and provide a very definite and detailed, though far from complete, analysis of the vibratory motions that are going on in it; these vibrations being in their normal state characteristic of its dynamical constitution, and in their deviations from the normal giving indications of the velocity of its movement and the physical state of its environment. Maxwell long ago laid emphasis on the fact that a physical atomic theory is not competent even to contemplate the vast mass of potentialities and correlations of the past and the future, that biological theory has to consider as latent in a single organic germ containing at most only a few million molecules. On our present view we can accept his position that the properties of such a body cannot be those of a "purely material system," provided, however, we restrict this phrase to apply to physical properties as here defined. But an exhaustive discovery of the intimate nature of the atom is beyond the scope of physics; questions as to whether it must not necessarily involve in itself some image of the complexity of the organic structures of which it can form a correlated part must remain a subject of speculation outside the domain of that science. It might be held that this conception of discrete atoms and continuous æther really stands, like those of space and time, in intimate relation with our modes of mental apprehension, into which any consistent picture of the external world must of necessity be fitted. In any case it would involve abandonment of all the successful traditions of our subject if we ceased to hold that our analysis can be formulated in a consistent and complete manner, so far as it goes, without being necessarily an exhaustive account of phenomena that are beyond our range of experiment. Such phenomena may be more closely defined as those connected with the processes of intimate combination of the molecules: they include the activities of organic beings which all seem to depend on change of molecular structure.

---

[1] We can here only allude to Lord Kelvin's recent most interesting mechanical illustrations of a solid æther interacting with material molecules and with itself by attraction at a distance: unlike the generalised dynamical methods expounded in the text, which can leave the intimate structure of the material molecule outside the problem, a definite working constitution is there assigned to the molecular nucleus. It is pointed out in a continuation that is to appear in the *Phil. Mag.* for September, that a density of æther of the order of only $10^{-9}$, which would not appreciably affect the inertia of matter, would involve rigidity comparable with that of steel, and thus permit transmission of magnetic forces by stress; this solid æther is, however, as usual, taken to be freely permeable to the molecules of matter.

If, then, we have so small a hold on the intimate nature of matter, it will appear all the more striking that physicists have been able precisely to divine the mode of operation of the intangible æther, and to some extent explore in it the fields of physical influence of the molecules. On consideration we recognise that this knowledge of fundamental physical interaction has been reached by a comparative process. The mechanism of the propagation of light could never have been studied in the free æther of space alone. It was possible, however, to determine the way in which the characteristics of optical propagation are modified, but not wholly transformed, when it takes place in a transparent material body instead of empty space. The change in fact arises on account of the æther being entangled with the network of material molecules; but inasmuch as the length of a single wave of radiation covers thousands of these molecules the wave-motion still remains uniform and does not lose its general type. A wider variation of the experimental conditions has been provided for our examination in the case of those substances in which the phenomenon of double refraction pointed to a change of the æthereal properties which varied in different directions; and minute study of this modification has proved sufficient to guide to a consistent appreciation of the nature of this change, and therefore of the mode of æthereal propagation that is thus altered. In the same way, it was the study and development of the manner in which the laws of electric phenomena in material bodies had been unravelled by Ampère and Faraday that guided Faraday himself and Maxwell—who were impressed with the view that the æther was at the bottom of it all—in their progress towards an application of similar laws to æther devoid of matter, such as would complete a scheme of continuous action by consistently interconnecting the material bodies and banishing all untraced interaction across empty space. Maxwell in fact chose to finally expound the theory by ascribing to the æther of free space a dielectric constant and a magnetic constant of the same types as had been found to express the properties of material media, thus extending the seat of the phenomena to all space on the plan of describing the activity of the æther in terms of the ordinary electric ideas. The converse mode of development, starting with the free æther under the directly dynamical form which has been usual in physical optics, and introducing the influence of the material atoms through the electric charges which are involved in their constitution,[1] was hardly employed by him; in part, perhaps, because, owing to the necessity of correlating his theory with existing electric knowledge and the mode of its expression, he seems never to have reached the stage of moulding it into a completely deductive form.

The dynamics of the æther, in fact the recognition of the existence of an æther, has thus, as a matter of history, been reached through study of the dynamical phenomena of matter. When the dynamics of a material system is worked up to its purest and most general form, it becomes a formulation of the relations between the succession of the configurations and states of motion of the system, the assistance of an independent idea of force not being usually required. We can, however, only attain to such a compact statement when the system is self-contained, when its motion is not being dissipated by agencies of frictional type, and when its connections can be directly specified by purely geometrical relations between the co-ordinates, thus excluding such mechanisms as rolling contacts. The course of the system is then in all cases determined by some form or other of a single fundamental property, that any alteration in any small portion of its actual course must produce an increase in the total "Action" of the motion. It is to be observed that in employing this law of minimum as regards the Action expressed as an integral over the whole time of the motion, we no more introduce the future course as a determining influence on the present state of motion than we do in drawing a straight line from any point in any direction, although the length of the line is the minimum distance between its ends. In drawing the line piece by piece we have to make tentative excursions into the immediate future in order to adjust each element into straightness with the previous element; so in tracing the next stage of the motion of a material system we have similarly to secure that it is not given any such directions as would unduly increase the Action. But whatever views may be held as to the ultimate significance of this principle of Action, its importance, not only for mathematical analysis, but as a guide to physical exploration, remains fundamental. When the principles of the dynamics of material systems are refined down to their ultimate common basis, this principle of minimum is what remains. Hertz preferred to express its contents in the form of a principle of straightness of course or path. It will be recognised, on the lines already indicated, that this is another mode of statement of the same fundamental idea; and the general equivalence is worked out by Hertz on the basis of Hamilton's development of the principles of dynamics. The latter mode of statement may be adaptable so as to avoid the limitations which restrict the connections of the system, at the expense, however, of introducing new variables; if, indeed, it does not introduce gratuitous complexity for purposes of physics to attempt to do this. However these questions may stand, this principle of straightness or directness of path forms, wherever it applies, the most general and comprehensive formulation of purely dynamical action: it involves in itself the complete course of events. In so far as we are given the algebraic formula for the time-integral which constitutes the Action, expressed in terms of any suitable co-ordinates, we know implicitly the whole dynamical constitution and history of the system to which it applies. Two systems in which the Action is expressed by the same formula are mathematically identical, are physically precisely correlated, so that they have all dynamical properties in common. When the structure of a dynamical system is largely concealed from view, the safest and most direct way towards an exploration of its essential relations and connections, and in fact towards answering the prior question as to whether it is a purely dynamical system at all, is through this order of ideas. The ultimate test that a system is a dynamical one is not that we shall be able to trace mechanical stresses throughout it, but that its relations can be in some way or other consolidated into accordance with this principle of minimum Action. This definition of a dynamical system in terms of the simple principle of directness of path may conceivably be subject to objection as too wide; it is certainly not too narrow; and it is the conception which has naturally been evolved from two centuries of study of the dynamics of material bodies. Its very great generality may lead to the objection that we might completely formulate the future course of a system in its terms, without having obtained a working familiarity with its details, of the kind to which we have become accustomed in the analysis of simple material systems; but our choice is at present between this kind of formulation, which is a real and essential one, and an empirical description of the course of phenomena combined with explanations relating to more or less isolated groups. The list of great names, including Kelvin, Maxwell, Helmholtz, that have been associated with the employment of the principle for the elucidation of the relations of deep-seated dynamical phenomena is a strong guarantee that we shall do well by making the most of this clue.

---

[1] In 1870 Maxwell, while admiring the breadth of the theory of Weber, which is virtually based on atomic charges combined with action at a distance, still regarded it as irreconcilable with his own theory, and left to the future the question as to why "theories apparently so fundamentally opposed should have so large a field of truth common to both."—"Scientific Papers," ii. p. 228.

Are we then justified in treating the material molecule, so far as revealed by the spectroscope, as a dynamical system coming under this specification? Its intrinsic energy is certainly permanent and not subject to dissipation; otherwise the molecule would gradually fade out of existence. The extreme precision and regularity of detail in the spectrum shows that the vibrations which produce it are exactly synchronous, whatever be their amplitude, and in so far resemble the vibrations of small amplitude in material systems. As all indications point to the molecule being a system in a state of intrinsic motion, like a vortex ring, or a stellar system in astronomy, we must consider these radiating vibrations to take place around a steady state of motion which does not itself radiate, not around a state of rest. Now not the least of the advantages possessed by the Action principle, as a foundation for theoretical physics, is the fact that its statement can be adapted to systems involving in their constitution permanent steady motions of this kind, in such a way that only the variable motions superposed on them come into consideration. The possibilities as regards physical correlation of thus introducing permanent motional states as well as permanent structure into the constitution of our dynamical systems have long been emphasised by Lord Kelvin;[1] the effective adaptation of abstract dynamics to such systems was made independently by Kelvin and Routh about 1877; the more recent exposition of the theory by Helmholtz has directed general attention to what is undoubtedly the most significant extension of dynamical analysis which has taken place since the time of Lagrange.

Returning to the molecules, it is now verified that the Action principle forms a valid foundation throughout electrodynamics and optics; the introduction of the æther into the system has not affected its application. It is therefore a reasonable hypothesis that the principle forms an allowable foundation for the dynamical analysis of the radiant vibrations in the system formed by a single molecule and surrounding æther; and the knowledge which is now accumulating, both of the orderly grouping of the lines of the spectrum and of the modifications impressed on these lines by a magnetic field or by the density of the matter immediately surrounding the vibrating molecule, can hardly fail to be fruitful for the dynamical analysis of its constitution. But let it be repeated that this analysis would be complete when a formula for the dynamical energy of the molecule is obtained, and would go no deeper. Starting from our definitely limited definition of the nature of a dynamical system, the problem is merely to correlate the observed relations of the periods of vibration in a molecule, when it has come into a steady state as regards constitution and is not under the influence of intimate encounter with other molecules.

It may be recalled incidentally that the generalised Maxwell-Boltzmann principle of the equable distribution of the acquired store of kinetic energy of the molecule, among its various possible independent types of motion, is based directly on the validity of the Action principle for its dynamics. In the demonstrations usually offered the molecule is considered to have no permanent or constitutive energy of internal motion. It can, however, be shown, by use of the generalisation aforesaid of the Action principle, that no discrepancy will arise on that account. Such intrinsic kinetic energy virtually adds on to the potential energy of the system; and the remaining or acquired part of the kinetic energy of the molecule may be made the subject of the same train of reasoning as before.

Let us now return to the general question whether our definition of a dynamical system may not be too wide. As a case in point, the single principle of Action has been shown to provide a definite and sufficient basis for electrodynamics; yet when, for example, one armature of an electric motor pulls the other after it without material contact, and so transmits mechanical power, no connection between them is indicated by the principle such as could by virtue of internal stress transmit the pull. The essential feature of the transmission of a pull by stress across a medium is that each element of volume of the medium acts by itself, independently of the other elements. The stress excited in any element depends on the strain or other displacement occurring in that element alone; and the mechanical effect that is transmitted is considered as an extraneous force applied at one place in the medium, and passed on from element to element through these internal pressures and tractions until it reaches another place. We have, however, to consider two atomic electric charges as being themselves some kind of strain configurations in the æther; each of them already involves an atmosphere of strain in the surrounding æther which is part of its essence, and cannot be considered apart from it; each of them essentially pervades the entire space, though on account of its invariable character we consider it as a unit. Thus we appear to be debarred from imagining the æther to act as an elastic connection which is merely the agent of transmission of a pull from the one nucleus to the other, because there are already stresses belonging to and constituting an intrinsic part of the terminal electrons, which are distributed all along the medium. Our Action criterion of a dynamical system, in fact, allows us to reason about an electron as a single thing, nothwithstanding that its field of energy is spread over the whole medium; it is only in material solid bodies, and in problems in which the actual sphere of physical action of the molecule is small compared with the smallest element of volume that our analysis considers, that the familiar idea of transmission of force by simple stress can apply. Whatever view may ultimately commend itself, this question is one that urgently demands decision. A very large amount of effort has been expended by Maxwell, Helmholtz, Heaviside, Hertz, and other authorities in the attempt to express the mechanical phenomena of electrical action in terms of a transmitting stress. The analytical results up to a certain point have been promising, most strikingly so at the beginning, when Maxwell established the mathematical validity of the way in which Faraday was accustomed to represent to himself the mechanical interactions across space, in terms of a tension along the lines of force equilibrated by an equal pressure preventing their expansion sideways. According to the views here developed, that ideal is an impossible one; if this could be established to general satisfaction the field of theoretical discussion would be much simplified.

This view that the atom of matter is, so far as regards physical actions, of the nature of a structure in the æther involving an atmosphere of æthereal strain all around it, not a small body which exerts direct actions at a distance on other atoms according to extraneous laws of force, was practically foreign to the eighteenth century, when mathematical physics was modelled on the Newtonian astronomy and dominated by its splendid success. The scheme of material dynamics, as finally compactly systematised by Lagrange, had therefore no direct relation to such a view, although it has proved wide enough to include it. The remark has often been made that it is probably owing to Faraday's mathematical instinct, combined with his want of acquaintance with the existing analysis, that the modern theory of the æther obtained a start from the electric side. Through his teaching and the weight of his authority, the notion of two electric currents exerting their mutual forces by means of an intervening medium, instead of by direct attraction across space, was at an early period firmly grasped in this country. In 1845 Lord Kelvin was already mathematically formulating, with most suggestive success, continuous elastic connections, by whose strain the fields of activity of electric currents or of electric distributions could be illustrated; while the exposition of Maxwell's interconnected scheme, in the earlier form in which it relied on concrete models of the electric action, goes back almost to 1860. Corresponding to the two physical ideals of isolated atoms exerting attraction at a distance, and atoms operating by atmospheres of æthereal strain, there are, as already indicated, two different developments of dynamical theory. The original Newtonian equations of motion determined the course of a system by expressing the rates at which the velocity of each of its small parts or elements is changing. This method is still fully applicable to those problems of gravitational astronomy in which dynamical explanation was first successful on a grand scale, the planets being treated as point-masses, each subject to the gravitational attraction of the other bodies. But the more recent development of the dynamics of complex systems depends on the fact that analysis has been able to reduce within manageable limits the number of varying quantities whose course is to be explicitly traced, through taking advantage of those internal relations of the parts of the system that are invariable, either geometrically or dynamically. Thus, to take the simplest case, the dynamics of a solid body can be confined to a discussion of its three components of translation and its three components of rotation, instead of the motion of each element of its mass. With the number of independent co-ordinates thus diminished, when the initial state of the motion is specified the subsequent course of the complete system can be traced; but the course of the changes in any part of it can only be treated in relation to the motion of the system as a whole. It is just this mode of treatment of a system as a whole that is the main characteristic of modern physical analysis. The way in which Maxwell analysed the interactions of a system of linear electric currents, previously treated as if each were made up of small independent pieces or elements, and accumulated the evidence that they formed a single dynamical system, is a trenchant example. The interactions of vortices in fluid form a very similar problem, which is of special note in that the constitution of the system is there completely known in advance, so that the two modes of dynamical exposition can be compared. In this case the older method forms independent equations for the motion of each material element of the fluid, and so requires the introduction of the stress—here the fluid pressure—by which dynamical effect is passed on to it from the surrounding elements: it corresponds to a method of contact action. But Helmholtz opened up new ground in the abstract dynamics of continuous media when he recognised (after Stokes) that, if the distribution of the velocity of spin at those places in the fluid where the motion is vortical be assigned, the motion in every part of the fluid is therein kinematically involved. This, combined with the theorem of Lagrange and Cauchy, that the spin is always confined to the same portions of the fluid, formed a starting-point for his theory of vortices, which showed how the subsequent course of the motion can be ascertained without consideration of pressure or other stress.

---

[1] For a classical exposition see his Brit. Assoc. Address of 1884 on "Steps towards a Kinetic Theory of Matter," reprinted in "Popular Lectures and Addresses," vol. i.

The recognition of the permanent state of motion constituting a vortex ring as a determining agent as regards the future course of the system was in fact justly considered by Helmholtz as one of his greatest achievements. The principle had entirely eluded the attention of Lagrange and Cauchy and Stokes, who were the pioneers in this fundamental branch of dynamics, and had virtually prepared all the necessary analytical material for Helmholtz's use. The main import of this advance lay, not in the assistance which it afforded to the development of the complete solution of special problems in fluid motion, but in the fact that it constituted the discovery of the types of permanent motion of the system, which could combine and interact with each other without losing their individuality,[1] though each of them pervaded the whole field. This rendered possible an entirely new mode of treatment; and mathematicians who were accustomed, as in astronomy, to aim directly at the determination of all the details of the special case of motion, were occasionally slow to apprehend the advantages of a procedure which stopped at formulating a description of the nature of the interaction between various typical groups of motions into which the whole disturbance could be resolved.

The new train of ideas introduced into physics by Faraday was thus consolidated and emphasised by Helmholtz's investigations of 1858 in the special domain of hydrodynamics. In illustration let us consider the fluid medium to be pervaded by permanent vortices circulating round solid rings as cores: the older method of analysis would form equations of motion for each element of the fluid, involving the fluid pressure, and by their integration would determine the distribution of pressure on each solid ring, and thence the way it moves. This method is hardly feasible even in the simplest cases. The natural plan is to make use of existing simplifications by regarding each vortex as a permanent reality, and directly attacking the problem of its interactions with the other vortices. The energy of the fluid arising from the vortex motion can be expressed in terms of the positions and strengths of the vortices alone; and then the principle of Action, in the generalised form which includes steady motional configurations as well as constant material configurations, affords a method of deducing the motions of the cores and the interactions between them. If the cores are thin they in fact interact mechanically, as Lord Kelvin and Kirchhoff proved, in the same manner as linear electric currents would do; though the impulse thence derived towards a direct hydrokinetic explanation of electro-magnetics was damped by the fact that repulsion and attraction have to be interchanged in the analogy. The conception of vortices, once it has been arrived at, forms the natural physical basis of investigation, although the older method of determining a distribution of pressure-stress throughout the fluid and examining how it affects the cores is still possible; that stress, however, is not simply transmitted, as it has to maintain the changes of velocity of the various portions of the fluid. But if the vortices have no solid cores we are at a loss to know where even this pressure can be considered as applied to them; if we follow up the stress, we lose the vortex; yet a fluid vortex can nevertheless illustrate an atom of matter, and we can consider such atoms as exerting mutual forces, only these forces cannot be considered as transmitted through the agency of fluid pressure. The reason is that the vortex cannot now be identified with a mere core bounded by a definite surface, but is essentially a configuration of motion extending throughout the medium.

Thus we are again in face of the fundamental question whether all attempts to represent the mechanical interactions of electro-dynamic systems, as transmitted from point to point by means of simple stress, are not doomed to failure; whether they do not, in fact, introduce unnecessary and insurmountable difficulty into the theory. The idea of identifying an atom with a state of strain or motion, pervading the region of the æther around its nucleus, appears to demand wider views as to what constitutes dynamical transmission. The idea that any small portion of the primordial medium can be isolated, by merely introducing tractions acting over its surface and transmitted from the surrounding parts, is no longer appropriate or consistent: a part of the dynamical disturbance in that element of the medium is on this hypothesis already classified as belonging to, and carried along with, atoms that are outside it but in its neighbourhood—and this part must not be counted twice over. The law of Poynting relating to the paths of the transmission of energy is known to hold in its simple form only when the electric charges or currents are in a steady state; when they are changing their positions or configurations their own fields of intrinsic energy are carried along with them.

It is not surprising, considering the previous British familiarity with this order of ideas, that the significance for general physics of Helmholtz's doctrine of vortices was eagerly developed in this country, in the form in which it became embodied through Lord Kelvin's famous illustration of the constitution of the matter, as consisting of atoms with separate existence and mutual interactions. This vortex-atom theory has been a main source of physical suggestion because it presents, on a simple basis, a dynamical picture of an ideal material system, atomically constituted, which could go on automatically without extraneous support. The value of such a picture may be held to lie, not in any supposition that this is the mechanism of the actual world laid bare, but in the vivid illustration it affords of the fundamental postulate of physical science, that mechanical phenomena are not parts of a scheme too involved for us to explore, but rather present themselves in definite and consistent correlations, which we are able to disentangle and apprehend with continually increasing precision.

It would be an interesting question to trace the origin of our preference for a theory of transmission of physical action over one of direct action at a distance. It may be held that it rests on the same order of ideas as supplies our conception of force; that the notion of effort which we associate with change of the motion of a body involves the idea of a mechanical connection through which that effort is applied. The mere idea of a transmitting medium would then be no more an ultimate foundation for physical explanation than that of force itself. Our choice between direct distance action and mediate transmission would thus be dictated by the relative simplicity and coherence of the accounts they give of the phenomena: this is, in fact, the basis on which Maxwell's theory had to be judged until Hertz detected the actual working of the medium. Instantaneous transmission is to all intents action at a distance, except in so far as the law of action may be more easily formulated in terms of the medium than in a direct geometrical statement.

In connection with these questions it may be permitted to refer to the eloquent and weighty address recently delivered by M. Poincaré to the International Congress of Physics. M. Poincaré accepts the principle of Least Action as a trustworthy basis for the formulation of physical theory, but he imposes the condition that the results must satisfy the Newtonian law of equality of action and reaction between each pair of bodies concerned, considered by themselves; this, however, he would allow to be satisfied indirectly, if the effects could be traced across the intervening æther by stress, so that the tractions on the two sides of each ideal interface are equal and opposite.[1] As above argued, this view appears to exclude *ab initio* all atomic theories of the general type of vortex atoms, in which the energy of the atom is distributed throughout the medium instead of being concentrated in a nucleus; and this remark seems to go to the root of the question. On the other hand, the position here asserted is that recent dynamical developments have permitted the extension of the principle of Action to systems involving permanent motions, whether obvious or latent, as part of their constitution; that on this wider basis the atom may itself involve a state of steady disturbance extending through the medium, instead of being only a local structure acting by push and pull. The possibilities of dynamical explanation are thus enlarged. The most definite type of model yet imagined of the physical interaction of atoms through the æther is, perhaps, that which takes the æther to be a rotationally elastic medium after the manner of MacCullagh and Rankine, and makes the ultimate atom include the nucleus of a permanent rotational strain-configuration, which as a whole may be called an electron. The question how far this is a legitimate and effective model stands by itself, apart from the dynamics which it illustrates; like all representations it can only cover a limited ground. For instance, it cannot claim to include the internal structure of the nucleus of an atom or even of an electron; for purposes of physical theory that problem can be put aside, it may even be treated as inscrutable. All that is needed is a postulate of free mobility of this nucleus through the æther. This is definitely hypothetical, but it is not an unreasonable postulate because a rotational æther has the properties of a perfect fluid medium except where differentially rotational motions are concerned, and so would not react on the motion of any structure moving through it except after the manner of an apparent change of inertia. It thus seems possible to hold that such a model forms an allowable representation of the dynamical activity of the æther, as distinguished from the complete constitution of the material nuclei between which that medium establishes connection.

---

[1] We may compare G. W. Hill's more recent introduction of the idea of permanent orbits into physical astronomy.

At any rate, models of this nature have certainly been most helpful in Maxwell's hands towards the effective intuitive grasp of a scheme of relations as a whole, which might have proved too complex for abstract unravelment in detail. When a physical model of concealed dynamical processes has served this kind of purpose, when its content has been explored and estimated, and has become familiar through the introduction of new terms and ideas, then the ladder by which we have ascended may be kicked away, and the scheme of relations which the model embodied can stand forth in severely abstract form. Indeed, many of the most fruitful branches of abstract mathematical analysis itself have owed their start in this way to concrete physical conceptions. This gradual transition into abstract statement of physical relations in fact amounts to retaining the essentials of our working models while eliminating the accidental elements involved in them; elements of the latter kind must always be present because otherwise the model would be identical with the thing which it represents, whereas we cannot expect to mentally grasp all aspects of the content of even the simplest phenomena. Yet the abstract standpoint is always attained through the concrete; and for purposes of instruction such models, properly guarded, do not perhaps ever lose their value: they are just as legitimate aids as geometrical diagrams, and they have the same kind of limitations. In Maxwell's words, "for the sake of persons of these different types scientific truth should be presented in different forms, and should be regarded as equally scientific whether it appear in the robust form and the vivid colouring of a physical illustration, or in the tenuity and paleness of a symbolical expression." The other side of the picture, the necessary incompleteness of even our legitimate images and modes of representation, comes out in the despairing opinion of Young ("Chromatics," 1817), at a time when his faith in the undulatory theory of light had been eclipsed by Malus's discovery of the phenomena of polarisation by reflection, that this difficulty "will probably long remain, to mortify the vanity of an ambitious philosophy, completely unresolved by any theory": not many years afterwards the mystery was solved by Fresnel.

This process of removing the intellectual scaffolding by which our knowledge is reached, and preserving only the final formulæ which express the correlations of the directly observable things, may moreover readily be pushed too far. It asserts the conception that the universe is like an enclosed clock that is wound up to go, and that accordingly we can observe that it is going, and can see some of its more superficial movements, but not much of them; that thus, by patient observation and use of analogy, we can compile, in merely tabular form, information as to the manner in which it works and is likely to go on working, at any rate for some time to come; but that any attempt to probe the underlying connection is illusory or illegitimate. As a theoretical precept this is admirable. It minimises the danger of our ignoring or forgetting the limitations of human faculty, which can only utilise the imperfect representations that the external world impresses on our senses. On the other hand such a remainder has rarely been required by the master minds of modern science, from Descartes and Newton onwards, whatever their theories may have been. Its danger as a dogma lies in its application. Who is to decide, without risk of error, what is essential fact and what is intellectual scaffolding? To which class does the atomic theory of matter belong? That is, indeed, one of the intangible things which it is suggested may be thrown overboard, in sorting out and classifying our scientific possessions. Is the mental idea or image, which suggests, and alone can suggest, the experiment that adds to our concrete knowledge, less real than the bare phenomenal uniformity which it has revealed? Is it not, perhaps, more real in that the uniformities might not have been there in the absence of the mind to perceive them?

No time is now left for review of the methods of molecular dynamics. Here our knowledge is entirely confined to steady states of the molecular system: it is purely statical. In ordinary statics and the dynamics of undisturbed steady notions, the form of the energy function is the sufficient basis of the whole subject. This method is extended to thermodynamics by making use of the mechanically available energy of Rankine and Kelvin, which is a function of the bodily configuration and chemical constitution and temperature of the system, whose value cannot under any circumstances spontaneously increase, while it will diminish in any operation which is not reversible. In the statics of systems in equilibrium or in steady motion, this method of energy is a particular case of the method of Action; but in its extension to thermal statics it is made to include chemical as well as configurational changes, and a new point appears to arise. Whether we do or do not take it to be possible to trace the application of the principle of Action throughout the process of chemical combination of two molecules, we certainly here postulate that the static case of that principle, which applies to steady systems, can be extended across chemical combinations. The question is suggested whether extension would also be valid to transformations which involve vital processes. This seems to be still considered an open question by the best authorities. If it be decided in the negative a distinction is involved between vital and merely chemical processes.

It is now taken as established that vital activity cannot create energy, at any rate in the long run, which is all that can from the nature of the case be tested. It seems not unreasonable to follow the analogy of chemical actions, and assert that it cannot in the long run increase the mechanical availability of energy—that is, considering the organism as an apparatus for transforming energy without being itself in the long run changed. But we cannot establish a Carnot cycle for a portion of an organism, nor can we do so for a limited period of time; there might be creation of availability accompanied by changes in the organism itself, but compensated by destruction and the inverse changes a long time afterwards. This amounts to asserting that where, as in a vital system or even in a simple molecular combination, we are unable to trace or even assert complete dynamical sequence, exact thermodynamic statements should be mainly confined to the activity of the existing organism as a whole; it may transform inorganic material without change of energy and without gain of availability, although any such statements would be inappropriate and unmeaning as regards the details of the processes that take place inside the organism itself.

In any case it would appear that there is small chance of reducing these questions to direct dynamics; we should rather regard Carnot's principle, which includes the law of uniformity of temperature and is the basis of the whole theory, as a property of statistical type confined to stable or permanent aggregations of matter. Thus no dynamical proof from molecular considerations could be regarded as valid unless it explicitly restricted the argument to permanent systems; yet the conditions of permanency are unknown except in the simpler cases. The only mode of discussion that is yet possible is the method of dynamical statistics of molecules introduced by Maxwell. Now statistics is a method of arrangement rather than of demonstration. Every statistical argument requires to be verified by comparison with the facts, because it is of the essence of this method to take things as fortuitously distributed except in so far as we know the contrary; and we simply may not know essential facts to the contrary. For example, if the interaction of the æther or other cause produces no influence to the contrary, the presumption would be that the kinetic energy acquired by a molecule is, on the average, equally distributed among its various independent modes of motion, whether vibrational or translational. Assuming this type of distribution to be once established in a gaseous system, the dynamics of Boltzmann and Maxwell show that it must be permanent. But its assumption in the first instance is a result rather of the absence than of the presence of knowledge of the circumstances, and can be accepted only so far as it agrees with the facts; our knowledge of the facts of specific heat shows that it must be restricted to modes of motion that are homologous. In the words of Maxwell, when he first discovered in 1860, to his great surprise, that in a system of colliding rigid atoms the energy would always be equally divided between translatory and rotatory motions, it is only necessary to assume, in order to evade this unwelcome conclusion, that "something essential to the complete statement of the physical theory of molecular encounters must have hitherto escaped us."

---

[1] *Cf.* also Hertz on the electro-magnetic equations, § 12, *Wied. Ann.*, 1890. The problem of merely replacing a system of forces by a statical stress is widely indeterminate, and therefore by itself unreal; the actual question is whether any such representation can be co-ordinated with existing dynamics.

Our survey thus tends to the result, that as regards the simple and uniform phenomena which involve activity of finite regions of the universal æther, theoretical physics can lay claim to constructive functions, and can build up a definite scheme; but in the domain of matter the most that it can do is to accept the existence of such permanent molecular systems as present themselves to our notice, and fit together an outline plan of the more general and universal features in their activity. Our well-founded belief in the rationality of natural processes asserts the possibility of this, while admitting that the intimate details of atomic constitution are beyond our scrutiny and provide plenty of room for processes that transcend finite dynamical correlation.

## *NOTES.*

M. Faye has been elected a Foreign Member of the Reale Accademia dei Lincei of Rome.

Dr. Oustalet has been appointed professor of zoology in the Paris Natural History Museum, in succession to the late Prof. Milne-Edwards.

We regret to see the announcement of the death of Mr. Henry Sidgwick, late professor of moral philosophy at Cambridge.

Sir John B. Lawes, Bart., F.R.S., whose agricultural experiments at Rothamsted are of world-wide renown, died on Friday last, at eighty-six years of age.

The announcement in *Science* that Prof. J. E. Keeler, director of the Lick Observatory, and the author of many important papers on astrophysics, died in San Francisco on August 12, from the effects of heart disease, will be received by astronomers with much regret. Prof. Keeler was only forty-three years of age.

It has been officially notified that a death which occurred in hospital at Glasgow on Monday in last week was due to true bubonic plague. The presence of the disease is suspected in several cases of illness under treatment.

The Committee on Water-tube Boilers in the Navy has now been completed by the selection of Dr. John Inglis, lately president of the Institution of Engineers and Shipbuilders in Scotland, and vice-president of the Institution of Naval Architects.

The Melbourne correspondent of the *Times* states that, in compliance with a request of the Royal Geographical Society and other British scientific bodies, Prof. Baldwin Spencer has received leave of absence from the Melbourne University for one year, to enable him to study the customs and beliefs of the natives of the northern portion of South Australia.

The Berlin Academy of Sciences has made the following grants, in addition to those already announced (p. 394): Dr. Holtermann, Berlin, for a botanical expedition to Ceylon, 4000 marks; Prof. Ludolf Krehl, Greifswald, for experiments on respiration, 1500 marks; Prof. Julius Tafel, Würzburg, for the continuation of his work on electrolysis, 100 marks; Dr. Benno Wandolleck, Dresden, for the investigation of the morphology of diptera, 800 marks.

The names of one hundred eminent Americans no longer living are to be engraved in the Hall of Fame of the New York University. *Science* states that the following names of men of science have been proposed: John Adams Audubon, Spencer F. Baird, Alexander D. Bache, Nathaniel Bowditch, William Chauvenet, Henry Draper, James P. Espy, Asa Gray, Robert Hare, Joseph Henry, Edward Hitchcock, Isaac Lea, Matthew Fontaine Maury, Marie Mitchell, Benjamin Peirce, David Rittenhouse, Benjamin Silliman, Benjamin Thompson, John Torrey.

The Marconi Wireless Telegraph Company have contracted to supply the Admiralty with Marconi apparatus for thirty-two ships and stations. The test of efficiency which has to be satisfied is that the instruments shall enable communication to be carried on between a fitted ship in Portsmouth Harbour and a fitted ship at Portland, a distance of about sixty-five miles, with a good deal of land between, including the Dorsetshire Hills, making it about ninety miles by sea. A trial set of the apparatus successfully fulfilled the conditions a few days ago.

The death is announced of Dr. W. H. Lowe, formerly president of the Royal College of Physicians of Edinburgh. Dr. Lowe held several important positions in Edinburgh, among others those of president of the Royal Medical Society, and vice-president, subsequently president, of the Royal Botanic Society. He was elected a Fellow of the Royal College of Physicians of Edinburgh in 1846, and president of that college in 1873. At the meeting of the British Medical Association in Edinburgh in 1875 he presided over the section of psychology, and delivered the address before that section.

The eleventh annual general meeting of the members of the Institution of Mining Engineers will be held at Bristol on Tuesday, September 18. Among the papers to be read, or taken as read, are the following:—The geological features of the Somerset and Bristol coal-field, with special reference to the physical geology of the Somersetshire Basin, by Mr. James McMurtrie; methods of working the thin coal-seams of the Bristol and Somerset coal-field, by Mr. George E. J. McMurtrie; the analogy between the gold "cintas" of Columbia and the auriferous gravels of California, by Mr. Edward Gledhill; the theory of the equivalent orifice treated graphically, by Mr. H. W. Halbaum; development and working of minerals in the Leon district, Spain, by Mr. J. A. Jones; and the geological age of the gold-deposits of Victoria, Australia, by Mr. James Stirling.

The programme of the meeting of the Iron and Steel Institute, to be held in Paris on September 18–21, under the presidency of Sir William Roberts-Austen, has just been issued.

The following are subjects of papers to be brought before the meeting:—The development of the iron and steel industries in France since 1889, by H. Pinget; iron and steel from the point of view of the "phase-doctrine," by Prof. Bakhuis-Roozeboom; iron and steel at the Paris Exhibition, by Prof. H. Bauerman; American methods of testing iron and steel, by Mr. Albert Ladd Colby; rolling-mills, by Mr. Louis Katona; the constitution of slags, by Baron H. von Jüptner; a new method of producing high temperatures, by Mr. Ernest F. Lange; the action of aluminium on the carbon of cast iron, by Messrs. Godfrey Melland and H. W. Waldron; the present position of the solution theory of carburised iron, by Dr. A. Stansfield; iron and phosphorus, with appendixes on (1) eutectics, (2) solid solutions, (3) method of determining free phosphide of iron in iron and steel, and (4) heat-tinting metal sections for microscopic examination, by Mr. J. E. Stead.

We learn from the *Forres, Elgin and Nairn Gazette* of August 29 that a serious flood, due to the bursting of the Sanquhar reservoir on the morning of August 23, wrought great havoc over the western part of Forres. Since the great Moray floods of 1829, described by Sir Thomas Dick Lauder, the district has not suffered such a disaster. In that year the Findhorn was the main cause of flooding; in the present case injury was done by the breaking down of the embankment which dammed up the waters in a valley on the Sanquhar estate to the east of the Findhorn and a little south of Forres. The dam formed a reservoir of from eight to twelve acres. On Wednesday morning, August 22, the area was only partially covered with water, from eight to ten feet below the level of the overflow. Within twelve hours an inch and a half of rain fell. The reservoir filled rapidly, and by 3 a.m. on Thursday the water was rushing down the overflow, which was only thirty feet wide. Shortly before 5 a.m. the immense breastwork burst outwards from top to bottom in one mass, about twenty feet wide, close to the overflow, and the waters rushed wildly out. Near by an iron bridge with a concrete pier, 30 feet broad and 4 feet thick, were carried away, an ash tree was uprooted, and the waters spread rapidly over the low grounds in a wave that gathered to a height of three or four feet. Sheaves of barley and oats were carried off, wooden outhouses were torn away, stone walls, iron railings, gates and glasshouses were broken down, doors were driven in and a number of villas and cottages were submerged for some time to a depth of from three to five feet. Fortunately no lives were lost.

With reference to the inquiry as to the functions of the protruding filaments of the caterpillar of the Puss Moth (p. 385), we have received communications from several correspondents, who all agree with Mr. W. F. Kirby (p. 413) in regarding the appendages as chiefly intended for driving away Ichneumon Flies.

A note in the *Electrician* refers to a curious effect produced by severe thunderstorms upon the glow lamps on the circuits of the Calcutta Electric Supply Co. It appears that immediately following each lightning flash the brightness of the glowing lamps has been observed to increase suddenly, gradually returning to the normal incandescence. This phenomenon has so frequently been observed that the engineers of the company have sought every possible explanation of the curious phenomenon, but have been unable to find any defect in their circuits—which are on the overhead wire system—that might offer an explanation. Indeed, the only conceivable explanation is one which appears so extraordinary that many may find considerable difficulty in accepting it. It is well known that carbon, acting as a coherer in a wireless telegraph apparatus, undergoes the usual sudden decrease in resistance when subjected to electric radiation. It is suggested that the carbon filaments of a glowing lamp may undergo a similar change when exposed to the influence of a tropical thunderstorm in its immediate vicinity. This sudden decrease in the resistance of the filament would, of course, produce a correspondingly rapid increase in its candle-power, after which the gradual self-decoherence of the carbon would account for the return of the lamp to its normal incandescence.

We have received an interesting account of the climate of Norway, by Mr. A. S. Steen, being a reprint from the Official Publication for the Paris Exhibition, 1900. As that country stretches through more than 13 degrees of latitude and extends nearly 300 miles beyond the Arctic Circle, the most varied shades of continental and maritime climates are represented within its confines. Mr. Steen has divided the country into south-east, west and north sections, this being in fact in accordance with nature's own division. In the inland districts of south-east Norway and Finmark we have examples of the most typical inland climate, viz. severe winter and relatively high temperature maxima in summer, and small rainfall; while along the whole length of coast-line the winter is unusually mild, the summer cool, and rain falls in abundance. The influence of the Gulf Stream can be traced all over the country, and it is one of the chief agencies to which Norway owes its condition as a civilised inhabited State to its farthest bounds on the shores of the Polar Sea. The following are quoted as some of the highest summer temperatures: in the south-east 86° and upwards, and 93° at Christiania (once only); on the south coast no higher temperature than 80°·5 has ever been recorded. In the west, temperatures of 88°·5, and once 93° at Vossevangen, have been recorded. In the northern section temperatures of 85° to 88° have been recorded, but in the most southern of the Lofoten Isles (in the middle of the ocean) the thermometer has never risen above 68°.

A paper, by Mr. A. E. Sunderland, on applications of electrochemistry in dye and print works, is published in the Society of Arts *Journal* (August 24). The requirements which should be fulfilled by a machine for electrical dyeing are considered to be as follows:—(1) The poles must not be of metal, but of carbon or biscuit porcelain, which conduct by becoming saturated with the electrolyte. (2) They must be as near to one another as possible. (3) The cloth must pass between the poles in the open width. (4) The poles may be perfectly smooth, and preferably cylindrical, revolving freely. These particulars are necessary, because in the ordinary passage of the electric current across any dye solution, the tendency of the dye is to concentrate itself around the negative pole, and not to circulate freely in the whole dye vessel; there is thus always a great danger of unevenness. In the finishing of goods the peculiar effect which is produced by calendering a piece in two different directions, one impression upon another, is well known. This is technically termed water-marking or moire, and is due to the irregular reflection from the surface of the material, one part of the light being totally reflected, and the other part dispersed. The effect can be introduced in several ways, one of which depends upon electricity. This process, Mr. Sunderland remarks, resolves itself practically into the local application of electrolysis. A platinum plate of suitable size is connected with the positive pole of the source of current. On this conducting surface is placed some absorbent material saturated with a solution of common salt. On this pad is placed the fabric to be water-marked, and the plate engraved with the water-mark connected with the negative terminal is pressed down upon it. The salt solution is decomposed, and a facsimile of the water-mark is printed on the cloth. To produce opaque designs, the absorbent material is saturated with a solution of barium chloride, which is decomposed on passing the current.

IN the *Atti dei Lincei*, ix. 2, Dr. A. Campetti describes experiments made with common salt and copper sulphate tending to prove that there exists a difference of potential between a solid salt and its unsaturated solution, this difference of potential being of the same order of magnitude and sign as the difference of potential between a more concentrated and a less concentrated solution of the same salt.

THE question as to whether evaporation from the surface of an electrified liquid produces a loss of electricity is one of considerable interest in connection with theories of atmospheric electricity. An investigation of this point is given by Signori A. Pochettino and A Sella in the *Atti dei Lincei*, ix. 1. The method employed was to examine the rate at which an electrified plate lost its charge under the varying conditions when its surface was dry or was covered with a layer of water, and when it was exposed to a current of dry air or air saturated with watery vapour. The results tabulated show that the loss is more rapid in dry air than in saturated air, that with saturated air the presence or absence of the layer of water makes no practical difference, but that with dry air the discharge is actually slightly less rapid when the plate is wet than when it is dry. It is inferred that evaporation does not produce loss of charge, that the difference between dry air and saturated air is due to the fact that the dry air was ionised, while all trace of ionisation had been removed from the saturated air, and that the greater insulation obtained with dry air by wetting the plate was due to the ionisation being partially removed by the evaporation from the plate.

IN a paper published in the *Proceedings* of the Cambridge Philosophical Society, Mr. Barrett-Hamilton suggests that the (pathological) changes of colour and form which occur in certain Salmonoids during the breeding season may afford a clue to the origin of secondary sexual characters in animals in general. "Once," writes the author, "the existence of such a primitive state of things characterised by growth or discoloration of the whole or part of the body is admitted, we have therein the starting-point whence natural selection by alteration, suppression or accentuation of the details might easily produce many or all the nuptial changes of animals as we now see them, evolving in each a structure suitable to its own particular need, whether in eye, as in the Eel, in snout, as in the Salmon, or in hind-limb, as in Lepidosiren.

*Indian Museum Notes* (vol. v. No. 1) contains an interesting paper, by Mr. E. E. Green, on Indian Scale-insects (Coccidæ), showing the great increase which has recently taken place in our knowledge of their various groups. So late as 1886 only seven Indian representatives of the family were recorded, the well-known Wax-insect (*Ceroplastes ceriferus*) being one. Now thirty-seven species, distributed among fourteen genera, are known from Continental India, although this represents only a very small proportion of the real number. Not only are these insects interesting from their structure and their beauty of form and colour, but some are of commercial importance. The remainder of the number treats of various insect pests, notably those infesting tea and coffee plants, and those destructive to cereals and crops.

THE distribution of the Ruff in Ireland forms the subject of an interesting paper, by Mr. C. L. Patten, in the *Irish Naturalist* for August.

THE July number of the *Agricultural Gazette* of New South Wales maintains the usual high and useful character of this journal, an article on the important part played by bacteria in soil being of especial interest to the scientific agriculturist.

FROM the Indian Museum we have received "Illustrations of the Shallow-Water Ophiuroidea collected by the *Investigator*," by Dr. R. Koehler, published by the trustees. The specimens described are figured in eight plates.

To the last issue of the *Journal* of the Asiatic Society of Bengal for 1899, Mr. F. Finn contributes a paper on Indian Weaver Finches (Ploceidæ), in the course of which he shows how a supposed new species has been named on a specimen of a well-known bird in its summer plumage.

MALACOLOGISTS will find much to interest them in the sheets of the *Proceedings* of the Philadelphia Academy last to hand, Mr. H. A. Pilsbry communicating four papers dealing respectively with the land snails of Japan, South America, Australia and Polynesia, and India.

*Science Gossip* for September contains an interesting article, by Mr. R. J. Hughes, on the colouring of shells, in which he demonstrates that the most common pigment among those of northern Europe is the sesquioxide of iron. Another paper in the same number forms the continuation of "Geological Notes in the Orange River Colony," by Major Skinner, R.A.M.G.

IN the July number of the *American Naturalist*, Prof. H. L. Osborn describes a remarkable Axolotl from Dakota, which appears different from any named form, and may indicate a new type. In the course of his paper the author raises the question whether we yet know the adult of the true Mexican Axolotl, the specimens that have developed into Salamanders being from the United States and perhaps specifically distinct.

WE have received three fascicules of the "Results of the Branner-Agassiz Expedition to Brazil," in course of publication in the *Proceedings* of the Washington Academy. Two of these, written by ladies, are devoted to Crustacea, while the third, by Mr. C. H. Gilbert, deals with the fishes. When ladies appear as authors of papers, it is much to be desired that they should prefix "Mrs." or "Miss" to their names, as it is otherwise often difficult to ascertain their proper titles.

MENTION in these columns has already been made of Mr. G. S. Miller's work on Old World mammals, and we have now received a paper, communicated by that naturalist to the *Proceedings* of the Washington Academy of Sciences (vol. ii. pp. 203–246), in which he describes a very large number of new species, mainly Rodents, collected by Dr. W. L. Abbott on islands in the North China Sea. Many of these are rats and mice.

THE publication of Prof. E. Morselli's free course of lectures on man from an evolutionary point of view is still proceeding, and the fascicules when bound together will form an interesting volume on physical anthropology, or, as the author terms it, *Antropologia générale*. The last number to hand (No. 45) concludes the section on the brain, and commences an account of the progenitors of man.

THERE is always something of interest in our well illustrated contemporary, *The Reliquary and Illustrated Archaeologist*. The July number contains some architectural notes from Monmouthshire, by Mr. J. Russell Larkby, illustrated by numerous sketches, and a short paper, by Mr. R. E. Head, on lace bobbins; these are often decorated in various ways, and different parts of the country furnish local types.

THOSE who are interested in criminal anthropology will find in a recent number of the *Bulletin de la Société d'Anthropologie de Paris* (Tome x. 4e série, p. 453) a psycho-physiological, medico-legal, and anatomical study of an atrocious criminal named Vacher, by MM. J.-V. Laborde, Manouvrier, Papillaut and Gellé. It is strange that studies of this kind are never made in this country. It is quite time that physical anthropology and psychology were more directly recognised by persons interested in criminology.

SIR ARCHIBALD GEIKIE'S "Outlines of Field Geology" (Macmillan) has been the counsellor and friend of many young geologists and intelligent observers of the earth's features. A new edition—containing numerous alterations and additions, while retaining the original form—has just been published, and it should be possessed by every lover of country rambles or teacher of earth-knowledge.

A BULKY volume, containing "Agricultural Statistics of British India for the years 1894–95 to 1898–99," has just been distributed by the Department of Revenue and Agriculture of the Government of India. The tables show (1) total average, classification of areas, irrigation, fallow land, area under crops, and stock; (2) prices of produce; (3) incidence of the land revenue on area and population; (4) varieties of tenure held direct from Government; (5) register of transfers of landed property; and (6) yields of principal crops.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*, ♂) from West Africa, presented by Mr. C. A. Gilbert; two Boschboks (*Tragelaphus sylvaticus*) from South Africa, presented by Dr. A. MacCarthy Morrough; a Rufous-necked Wallaby (*Macropus ruficollis*) from New South Wales, presented by Miss Seymour; a Germain's Peacock Pheasant (*Polyplectron germaini*) from Cochin China, presented by Mr. Arthur Yates; a Common Boa (*Boa constrictor*) from South America, presented by Mr. G. R. Fairbanks; two Red-bellied Squirrels (*Sciurus variegatus*) from South America, a Yellow-fronted Amazon (*Chrysotis ochrocephala*) from Guiana, ten Roofed Terrapins (*Kachuga tectum*) from India, deposited; a Wapiti Deer (*Cervus canadensis*), two Collared Fruit Bats (*Cynonycteris collaris*), born in the Gardens; two White Ibises (*Endocimus albus*), bred in the Gardens.

## *OUR ASTRONOMICAL COLUMN.*

EPHEMERIS FOR OBSERVATIONS OF EROS.—In the last issue of the *Astronomische Nachrichten* (Bd. 153, No. 3660), Signor E. Millosevich gives a revised ephemeris of this asteroid for the next few weeks:—

*Ephemeris for 12h. Berlin Mean Time.*

| 1900. | R.A. h. | m. | s. | Decl. ° | ′ | ″ |
|---|---|---|---|---|---|---|
| Sept. 6 | 2 | 27 | 24·16 | +35 | 29 | 53·7 |
| 7 | | 28 | 28·18 | 35 | 52 | 13·0 |
| 8 | | 29 | 30·73 | 36 | 14 | 36·1 |
| 9 | | 30 | 31·77 | 36 | 37 | 2·8 |
| 10 | | 31 | 31·22 | 36 | 59 | 33·0 |
| 11 | | 32 | 29·03 | 37 | 22 | 6 8 |
| 12 | | 33 | 25·13 | 37 | 44 | 43·9 |
| 13 | 2 | 34 | 19·43 | +38 | 7 | 24·2 |

COMET SWIFT (1894 IV).—Mr. F. H. Seares has calculated the osculating elements, and from them computed a finding ephemeris for this comet, which may possibly have some connection with the lost comet of De Vico. As it is important, however, that the comet should again be observed before any further attempt is made to establish such connection, he hopes that all possessing the necessary optical power will prosecute the search for it (*Astronomische Nachrichten*, Bd. 153, No. 3656).

*Osculating Elements.*

Epoch and Osculation 1900 July 23·0 Berlin Mean Time.

$$\begin{array}{l} M = 317^\circ\ 16'\ 15''\cdot0 \\ \left.\begin{array}{l} \pi = 348\ 56\ 56\cdot0 \\ \Omega = \ 24\ 50\ 38\cdot8 \\ i = \ \ 3\ 35\ 17\cdot0 \end{array}\right\} 1900\cdot0 \\ \phi = \ 31\ \ 2\ 30\cdot2 \\ \mu = 554''\cdot3823 \end{array}$$

*Ephemeris for Berlin Mean Midnight.*

THE NEW SPECTROGRAPHS FOR THE POTSDAM GREAT REFRACTOR.—In the *Astrophysical Journal*, vol. xi. pp. 393–399, Prof. H. C. Vogel describes the two new spectrographs which have recently been completed for the great Potsdam refractor of 80 cm. aperture.

(*a*) *Three-prism spectrograph.*—This is designed so that the combined deviations of the three prisms shall be nearly 180°, thus bringing the collimator and camera almost parallel. These are then mounted on a massive steel plate 78 cm. long, 41 cm. broad, and 7 mm. thick, which in its turn is firmly attached to the tail-piece of the telescope by an elliptical base plate 10 mm. thick, lateral flexure being guarded against by several intermediate metal ribs. The slit has only one movable jaw, and the whole can be rotated round the telescope axis, and the position angle recorded to 1′ of arc. For comparison spectra the arc light has been found most convenient, the difficulty of spectral displacement of comparison lines due to imperfect adjustment of source having been overcome by interposing a translucent diffusing screen between the light and slit. The collimator lens (Steinheil) has an aperture of 3·2 cm.; focal length, 48 cm. One of the camera objectives is a Zeiss anastigmat of 56 cm. focus; the other a triple cemented lens by Steinheil of 4·1 cm. aperture; focus, 41 cm. The prisms are of very white Jena glass, and with the Zeiss camera lens a spectrum of uniform focus from *b* to K is obtained. Delicate arrangements have been made for securing constant temperature conditions, &c. The weight of the complete spectrograph is 31 kilog.

(*b*) *Single-prism spectrograph.*—In this instrument the collimator lens is 3·5 cm. aperture, focus 53 cm.; the camera lens, 4 cm. aperture, focus 72 cm., both being triple cemented objectives by Steinheil. The prism is by Zeiss, and has a refracting angle of 60°, with faces 61 mm. long and 45 mm. high. The spectrum is uniformly sharp from D to N. The whole instrument weighs 20 kilograms.

Prof. Vogel gives the results of the application of tests instituted by Prof. W. W. Campbell for the Mills' spectrograph of the Lick Observatory, showing that the performance of both instruments is very trustworthy. Three plates are given showing the instruments in position as attached to the telescope.

STRUCTURE AND CONSTITUTION OF TWO NEW METEORITES.—Messrs. G. P. Merrill and H. N. Stokes recently communicated a paper to the Washington Academy of Sciences (*Proceedings*, vol. ii. pp. 41–68, July 1900), describing the results of their examination of two fragments of newly-fallen meteorites. One, a stony meteorite, fell on July 10, 1899, in Allegan, Michigan, U.S.A., the largest fragment weighing 62½ lbs. To the unaided eye this stone shows on the broken surface a quite even granular structure of grey colour, and, on closer examination, numerous beautifully spherulitic chondrules, averaging not more than one or two millimetres in diameter. In some cases these chondrules have pitted surfaces. More critical inspection indicates that they are composed of enstatite and olivine. Numerous brilliant metallic points of a silver-white colour indicate the presence of disseminated iron, so that the stone may be said to be made up of the chondrules, iron and dark grey silicate minerals, imbedded in a light ashy grey matrix. This Allegan stone is exceedingly friable. Microscopically, the ground mass of the stone is seen to be made up of a confused agglomerate of olivine and enstatite particles with interspersed metallic iron, iron sulphide and chromic iron. An important feature is that in no cases do the silicates occur with perfect crystallographic outlines, both olivine and enstatite being fragmental. The presence of alumina and alkalis suggested a search for felspar, but it was decided that this mineral was not present. A considerable proportion of the ground mass was found microscopically to be composed of a black glassy material. Careful chemical analysis showed that 77 per cent. of the meteorite was of non-metallic origin, the remainder being chiefly iron and nickel. The second meteorite examined is known as the Mart Iron, having been found early in 1898 near Mart, in Texas. This originally weighed 15¾ lbs., from which a slice weighing 456 grams was presented to the National Museum at Washington. The etched surface shows the iron to belong to the octahedral variety, and is of moderately coarse crystallisation. Chemical analysis showed that 98·3 per cent. of the meteorite was composed of the metals iron, nickel, copper, cobalt, the remainder being made up of schreibersite and a small quantity of troilite.

Photographs of both meteorites in their present condition are given, and numerous drawings indicating the microscopical structure.

## LATITUDE-VARIATION, EARTH-MAGNETISM AND SOLAR ACTIVITY.

IN the *Astronomische Nachrichten* (No. 3619) I have published the results of an investigation dealing with the effects of periodic changes in solar activity on the motion of our planet. It is there shown that these changes, as indicated by the frequency of sun-spots, exert a subtle but pregnant influence on the secular variations of the earth's elements; and, moreover, that disturbances precisely similar to those which appear in the observations of the obliquity and of the sun's longitude are distinctly exhibited in the variation of terrestrial latitude.

In the further pursuit of these researches I have been led to conclude that the anomalies existing in the observations of the sun's right-ascensions and declinations are to be attributed exclusively to changes in the position of the earth's axis of rotation with regard to the axis of maximum moment of inertia, and that these changes in their turn are intimately connected with the varying display of forces on the solar surface. In a subsequent article which appeared in NATURE (No. 1584, March 8) I made a suggestion as to the nature of this connection, and advanced the hypothesis that the magnetism of the earth is probably the medium through which the changes of solar energy react upon the motion of the earth's pole.

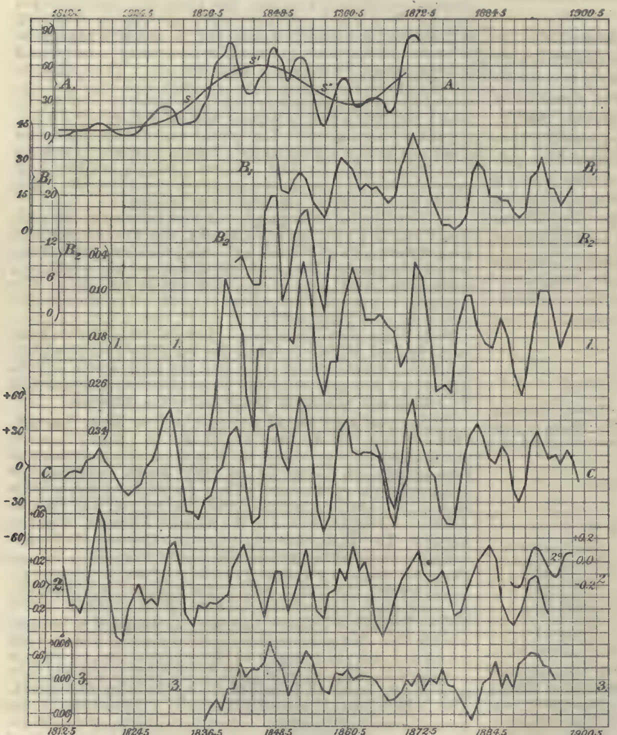

*Fig. I.*
*(From "Ast. Nach." 3649)*

A, frequency of auroræ (Loomis); B1, frequency of magnetic disturbances at Greenwich (Ellis); B2, frequency of magnetic disturbances at Greenwich (Airy); C, frequency of auroræ (Europe south of Arctic Circle) from 1812–1871 (Fritz), and in Scotland from 1865–1899. The "great" period has been eliminated in both curves in order to exhibit more clearly the eleven-years' fluctuations. 1, semi-amplitudes of latitude-variation (Chandler, Nyrén and Albrecht); 2, residuals of obliquity (Fig. C in *A.N.* 3619); 3, Greenwich corrections to the R.A. of stars derived from observations of the sun (Thackeray).

In view of the results of Joule's experiments regarding magnetic strain in iron rods, it seems reasonable to believe that something similar to the molecular displacement in the rod may take place in a magnetic body like our earth with respect to its magnetic axis. As has long been known, this axis is by no means coincident with the earth's axis of figure, but is inclined to it, according to Gauss, at an angle of about 12°. It is therefore not unnatural to conclude that a molecular strain in the direction of the magnetic axis will occasion an asymmetric change of the earth's figure, and will thereby produce a displacement of the axis of figure relative to the instantaneous axis of rotation. Such a displacement could remain constant only so long as the total magnetic potential of the earth was not subject to alteration, in which case the pole of rotation would describe a circle of constant radius round the pole of figure as centre. But, as already stated, various facts compel us to believe that the magnetic potential of the earth does alter, and, indeed, changes synchronously with the state of solar activity—the most striking instance being the regular increase of auroræ and of magnetic disturbances with the increasing frequency of sun-spots. Now, if we consider auroræ as discharges of the earth's electric force, it follows that the strain in the direction of the magnetic axis should abate after an auroral display, and the pole of figure should therefore approach the pole of instantaneous rotation.

The outcome of this hypothesis would be that changes in the state of solar activity, since they produce a measurable effect on the terrestrial magnetic forces, should also be accompanied by corresponding changes in the motion of the earth's axis. In *A.N.* 3649 I have endeavoured to test this theory by such facts as have up to the present been discovered regarding the complex phenomenon of latitude-variation, and I shall here briefly describe the results there obtained.

In the first place, from the material afforded by the investigations of Loomis and Fritz, and from observations made in Scotland during the past thirty years, I constructed curves exhibiting the frequency of auroral displays from 1812 to 1899. (Fig. 1, curves A and C.) In these the influence of the eleven-years solar period is most conspicuous, but there is also exhibited an intimate connection with the "great" cycle of sun-spots. In contrast with the spot-curve, minima of auroræ are found to be of unequal heights. Accordingly, if a second curve $ss's''$ be drawn through the aurora-curve A in such a way as to bisect as nearly as possible every wave appearing in it, this new curve will be seen to attain its maxima and minima simultaneously with the "great" spot period. It is therefore beyond dispute, as already proved by Wolf and Fritz, that the existence of this "great" period of solar activity is an established fact, and that it is clearly brought out by the curve of auroræ.

In the next place, curves were formed to show the variations in the frequency of terrestrial magnetic disturbances. For this purpose I took the annual number of days on which such disturbances were observed at Greenwich, as recorded by Mr. Ellis in *Monthly Notices* 60, December 1899. (Fig. 1, curve $B_1$.)

Mr. Ellis subdivides his records according to the intensity of the disturbance, but only three of his subdivisions were taken into account; those, namely, showing the frequency of moderate, active, and great disturbances respectively. For the satisfactory combination of these different sets, the principle was adopted that the weight assigned to each set should be inversely proportional to the mean frequency—unit weight being given to the "active" disturbances—on the ground that the small frequency of "great" disturbances is probably compensated for by their much more energetic character. In order to extend the record as far back as possible, a similar curve (Fig. 1, $B_2$) was constructed, based on Airy's statistics from 1841–1857 (*Trans. Roy. Soc.*, vol. cliii.).

These magnetic curves are in perfect harmony with those of the auroræ, and both sets bring out a remarkable and, for our purpose, eminently important fact, namely, that although for the most part they correspond closely with the eleven-years spot period, there nevertheless appear waves which at first sight seem to have nothing to do with the display of solar activity. Most noticeable in this respect are the maxima of 1852 and 1864, of which the former especially seems almost to contradict the existence of a connection between sun-spots and auroræ. A closer examination of the spot-curves, however, reveals the fact that in these two instances there occurred, at exactly the same times, peculiar disturbances or irregularities in the exhibition of spots on the solar surface, so that, after all, the waves exhibited at these points in the magnetic and auroral curves may be supposed to have been caused by solar influence, although they appear for some reason or other on a greatly exaggerated scale. This is decidedly the opinion of Prof. Fritz and of Mr. Ellis, both of whom expressly mention instances of this character, the latest having occurred in 1898 following the spot-maximum of 1894.

The succeeding part of this research may be conveniently divided into two parts. In the first, the earth-magnetic variations are compared and contrasted, in relation to the eleven-years period of sun-spots, with certain phenomena associated more or less directly with latitude-variation; and in the second with similar phenomena relative to the "great" sun-spot and aurora period.

These phenomena are:—

I. With regard to the eleven-years period—

i. The semi-amplitudes of latitude-variation.

ii. The periods of latitude-variation.

iii. The changes in the values of the obliquity as observed at Greenwich from 1812–1896.

iv. Mr. Thackeray's corrections to the right-ascensions of stars derived from observations of the sun during the years 1836–1895.

II. With regard to the "great" period—

v. Dr. Chandler's long period inequality in the latitude-variation.

vi. The observed residuals of the obliquity from 1753–1896 as compared with Leverrier's tabular values.

vii. The Greenwich corrections to the sun's right-ascensions relative to a fundamental system of fixed stars, according to Prof. Newcomb.

The data requisite for the formation of the curve of semiamplitudes (Fig. 1, curve 1) was taken from Dr. Chandler's paper in *A.J.* No. 277, and from the publications of Dr. Nyrén (*A.N.* 3166), Mr. Wanach (*A.N.* 3112) and Prof. Albrecht ("Berichte über den Stand der Erforschung der Breitenvariation"). It has to be borne in mind, as pointed out in my previous papers, that the latitude phenomenon lags behind the comparison magnetic curves by about 1·5 years. Such a lag appears indeed to be a characteristic feature common to most terrestrial phenomena which have hitherto been found to be influenced by solar activity. In this connection I must refer to the highly important and interesting discovery made by Sir Norman Lockyer some years ago, that the curve representing the frequency of the "unknown" lines widened in sun-spot spectra during a cycle of solar activity follows the spot-curve by exactly the same interval, viz. 1·5 years. I have received a communication from Sir Norman, stating that this curve of "unknown" lines goes excellently with my curve 1 of Fig. 1, the maxima and minima of the spectroscopic curves showing a perfect synchronism with those of the curve of latitude-variation. I take this opportunity of expressing my indebtedness to Sir Norman Lockyer for drawing my attention to this most significant and singular fact.

The lag in the case of curve 1 has been allowed for by shifting this curve one and a half years in the backward direction. When it has thus been made to coincide with the comparison curves, their correspondence becomes most striking—a remarkable feature being the exactness with which certain secondary maxima in 1865, 1887 and 1898 are represented in each case.

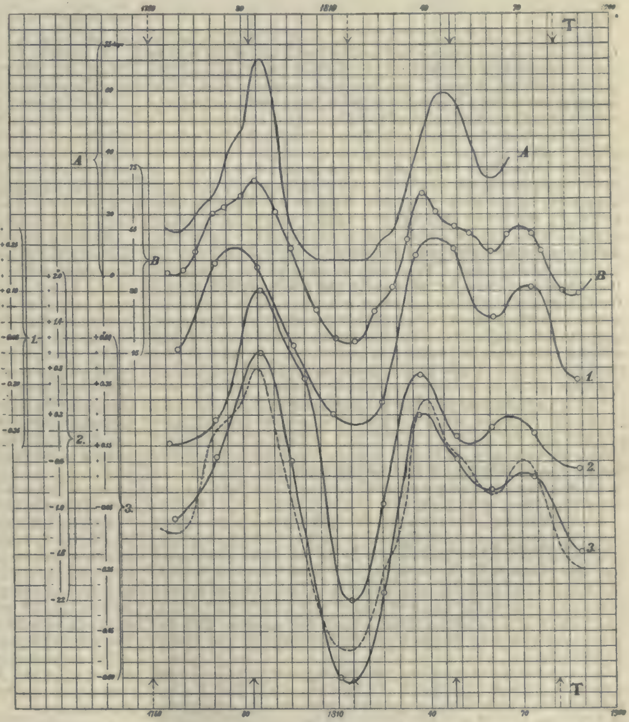

Fig. II.
(From "Ast. Nach."
3649.)

T, turning points of Dr. Chandler's long period inequality of latitude-variation; A, great period of auroræ (Loomis). (The ordinates represent eleven-years' means of Loomis' annual aurora-numbers.) B, great period of sun-spots (Wolf); 1, twelve-years' means of residuals of obliquity (Greenwich observations) after elimination of purely secular change; 2, twelve-years' means of corrections to the sun's R. A. relative to a system of fixed stars (Greenwich observations) after elimination of purely secular change; 3, combined curve of obliquity and sun's R.A., the dotted curve representing Wolf's great period of sun-spots on a somewhat different scale.

Indeed, so accurately are the motions of the amplitude-curve shadowed in those of the magnetic variations, that to any unprejudiced astronomer this fact in itself must indicate with sufficient force the existence of a *vera causa*.

The periods of latitude-variation afford a new and almost as certain proof of the existence of an intimate connection between the polar motion and earth-magnetic phenomena.

Dr. Chandler has already shown that a small amplitude corresponds to a great period and *vice versâ* (*A.J.* 277, p. 98). How well this influence is borne out may be seen from the following analysis of the average values of $r$ according to the lengths of the period:—

| Period in days. | Observed *r*. | Computed *r*. |
|---|---|---|
| | ″ | ″ |
| Under 390 | 0·20 | 0·20 |
| 390–420 | 0·18 | 0·19 |
| 420–450 | 0·15 | 0·13 |
| Over 450 | 0·10 | 0·08 |

This statement in itself constitutes a proof of my assertion, and renders it unnecessary for me to add anything further on this point. Any one who cares to plot down the values for the periods given by Dr. Chandler must arrive at the conclusion that the comparison of the curve so obtained, with the magnetic and auroral curves, gives indeed a convincing argument in favour of the earth-magnetic hypothesis.

I have next to consider the changes in the values of the obliquity as observed at Greenwich due to the eleven-years period of solar activity.

In my paper, *A.N.* 3619, I have discussed fully the reduction of these values to a uniform and homogeneous system, as well as the elimination from them of the secular variation and the influence of the "great" sun-spot and aurora period. The resulting curve (Fig. 1, curve 2) exhibits the utmost conformity with those of the earth-magnetic and latitude phenomena.

This fact is of the highest significance, inasmuch as it affords added testimony to the accuracy of the data on which my research is founded. The curves communicated show that at times, when the amplitude of latitude-variation reaches maximum values (1½ years after minimum displays of magnetic disturbance), the Greenwich obliquity attains small values; while at times, when the amplitude is at a minimum (1½ years after maximum displays of magnetic disturbance), the obliquity appears to be excessively great. This leads at once to the conclusion that whenever the amplitude is great, the minimum latitude for the Greenwich meridian must occur near the time of the winter solstice, and that when the amplitude is small just the reverse ought to take place. Now Dr. Chandler's statistics in *A.J.* 277 afford ample means of testing this conclusion. In point of fact they show that at times of maximum amplitude the epochs of minimum latitude for the Greenwich meridian have always occurred on some date between the beginning of November and the end of February, while at times of amplitude-minima these epochs, with the exception of the first in 1840, are comprised within the interval from May to August. The mean date in the former case is January 10, and in the latter July 16; and the mean deviation of a single epoch from these two dates is not more than about ± 40 days.

I consider that, in spite of the great uncertainty which naturally attaches to researches of so delicate a character, the evidence afforded by these results is to be taken as a proof that the residuals in the obliquity, far from being accidental, are really caused by latitude-variation. Thus, owing to the great extension of the series of Greenwich solar observations, these residuals form an excellent test of my assertion that the motion of the pole depends on the intensity of the earth-magnetic forces.

As regards the corrections to the right-ascensions of the stars derived from Greenwich observations of the sun, I need only state that after subtracting the secular variation found by Mr. Thackeray (*M.N.* June 1896), the resulting values give curve 3 of Fig. 1, which, in spite of somewhat large accidental discrepancies, is in general agreement with all the others, especially with that of the obliquity.

Having thus shown that my contention with regard to a connection between the eleven-years period of auroral displays and magnetic disturbances and the motion of the earth's pole of rotation appears to be borne out by all the facts which constitute the sum of our present knowledge of the peculiar phenomena relating to latitude-variation, I next consider the "great" period of auroræ, which, as already stated, is synchronous with the great period of solar activity.

For this purpose I exhibit in Fig. 2 curves showing the great aurora-period according to Loomis' annual numbers, and the great spot-period in Wolf's relative numbers.

The interval comprised by this great period is according to Wolf equal to six small cycles, *i.e.* sixty-six years. Now this is exactly the period of Dr. Chandler's long inequality of latitude-variation. The smallest amplitudes and greatest periods of latitude-variation, according to Chandler's formula, fell in 1782 and 1848, almost exactly at the times of greatest auroral displays; whereas the greatest amplitudes and smallest periods occurred in 1815 and 1881, *i.e.* just at the times when the display of auroræ reached a minimum.

But in addition to this there are other facts which point to an influence on the earth's motion exercised by some force varying with the great period of solar activity. In my previous papers I have discussed at some length the evidence afforded by the curves representing the observed residuals of the obliquity, and Prof. Newcomb's corrections to the right-ascension of the sun relative to a fundamental system of fixed stars. I therefore need not here dwell upon their importance as strongly supporting my hypothesis.

A reference to curves 1, 2 and 3 of Fig. 2 will show how exquisitely parallel are their courses, and how complete is their agreement, not only with the changes in the displays of auroræ and solar activity, but also with Dr. Chandler's long period inequality. It seems utterly inconceivable that a correspondence so consistent can be attributed merely to accident.

It remains to state briefly one or two very important and interesting deductions made from the results of the last ten years' researches into the phenomena of latitude-variation.

The frequency of auroræ and magnetic disturbances, as is well known, shows, in addition to the variations associated with changes of solar activity, other fluctuations depending on the season of the year—a fact which has been closely investigated and corroborated by Mr. Ellis. It appears that the magnetic disturbances recorded at Greenwich reveal decided maxima at the equinoxes and minima at the solstices, thus betraying, like the auroræ, a half-yearly period.

Now the foregoing results point to the conclusion that the distance of the pole of instantaneous rotation from the pole of figure depends on the display of earth-magnetic forces. Hence in the course of a year this distance must become twice comparatively short and twice comparatively long; *i.e.* instead of being circular, the path described by the pole of rotation round the pole of figure must be elliptical—the mean pole being situated at the centre of the ellipse. If the period of polar motion were exactly one year, the position of the axes of this ellipse referred to a fixed meridian would remain unaltered. But from Dr. Chandler's investigations we know the period of latitude-variation to be on the average 428 days. Hence the effect of seasonal change in the earth-magnetic forces must consist in continuously rotating the axes of the polar ellipse in a direction opposite to that of the motion of the pole. These conclusions are well corroborated by the observed facts, and are clearly revealed in the plate appended to Prof. Albrecht's latest "Bericht." The comparatively great eccentricity of the ellipses admits of a tolerably accurate determination of the angles between their major axes and the Greenwich meridian. If the magnitudes of these angles be computed (Table vi. of my paper, *A.N.* 3649), it will be found that they exhibit quite unmistakably the progressive change of position of the ellipse with regard to the meridian, the average angular distance between two successive positions of the major axes being about 33°.

But a closer examination of these figures shows that they indicate fluctuations in this average amount which stand in a remarkable connection with the varying display of magnetic disturbances.

The motion of the ellipse appears to have been largely progressive in 1892, 1894 and 1898; while it has been very slight, and at times even retrograde, in 1890, 1893 and 1896. In the first-mentioned years the ellipses are also more irregular and distorted than in the others, indicating a more vehement and spontaneous character of the forces acting on the motion of the pole. Now, according to Mr. Ellis, these years were the *only ones* in which magnetic disturbances of the character "great" occurred at Greenwich, while in the last-named years his statistics show that there prevailed a decided magnetic calm. While leaving the final confirmation of this interesting fact to future observations, it does not seem too much to say that in the face of existing evidence it is difficult to retain the idea that a coincidence so peculiar can possibly be ascribed to mere accident.

The results of my researches may be thus shortly summarised:—

i. The changes in the motion of the pole of rotation round the pole of figure are in an intimate connection with the variations of the earth-magnetic forces.

ii. Inasmuch as the latter phenomena are in a close relation with the state of solar activity, the motion of the pole is also indirectly dependent on the dynamical changes taking place at the sun's surface.

iii. The distance between the instantaneous and mean poles decreases with increasing intensity of earth-magnetic disturbance.

iv. The length of the period of latitude-variation increases with increasing intensity of earth-magnetic disturbance.

v. In strict analogy with the phenomena of auroræ and of magnetic disturbance, the influence of the eleven-years period of sun-spots, as well as of the "great" period, is clearly exhibited in the phenomenon of latitude-variation; and the same deviations from the solar curve as are manifested by the auroræ are also evident in the motion of the pole.

vi. The half-yearly period of the earth-magnetic phenomena influences the motion of the pole of rotation in such a way that its path, instead of being circular, assumes the form of an ellipse, having the mean pole at its centre.

vii. The half-yearly period also explains the conspicuous fact of a rotation of the axes of the ellipse in a direction opposite to that of the motion of the pole.

J. Halm.

## *UNIVERSITY AND EDUCATIONAL INTELLIGENCE.*

Prof. J. G. MacGregor, of Dalhousie University, Halifax, Nova Scotia, has been appointed professor of physics in University College, Liverpool, in succession to Prof. Lodge.

The Calendar of the Glasgow and West of Scotland Technical College, for the session 1900–1901, has been received. Among the contents of the volume we are glad to notice schemes of courses of study, extending over three years, for students who intend to take up some branch of applied science or engineering as a profession. Students are permitted to attend single classes, but they are encouraged to follow one of the regular courses in the several departments of study. This is the only way to derive any real advantage from a Technical College, desultory attendance at classes without any definite object being of little value.

At a special meeting of the University Court of St. Andrews, held on Saturday last, the proposal of the Marquis of Bute, who offered a sum of 20,000*l.* to be held as a fund for endowing a chair of anatomy in the University, was considered. After deliberation, the Court resolved cordially to accept the proposed gift on the conditions as stipulated by his lordship, and to request the Lord Rector to inform Lord Bute of the Court's decision. The Court further resolved to proceed at once with the creation of a professorship of anatomy at St. Andrews, to be endowed by Lord Bute's gift, the first presentation to the chair being Dr. Musgrove, the present lecturer in anatomy, such presentation to be made as soon as the ordinance creating the chair is approved by her Majesty in Council.

The mission of science in education was recently considered in some detail by Prof. J. M. Coulter in an address delivered at the University of Michigan, and published in *Science*. The claims set forth in the paper are formulated as follows:—The introduction of science among the subjects used in education has revolutionised the methods of teaching, and all subjects have felt the impulse of a new life; it has developed the scientific spirit, which prompts to investigation, which demands that belief shall rest upon a foundation of adequate demonstration, which recognises that the sphere of influence surrounding facts may be speedily traversed and that everything beyond is as uncertain as if there were no facts; it has introduced a training peculiar to itself, in that it teaches the attitude of self-elimination, an attitude necessary in order to reach ultimate truth, and thus supplements and steadies the other half of life, which is to appreciate. To obtain these results, there must be teachers who can teach, whose background and source of supply is the investigator. Moreover, the results are immensely desirable, inasmuch as they do not interfere with anything that is fine and uplifting in the old education, but simply mean that the possibilities of high attainment and high usefulness are open to a far greater number.

Messrs. S. Z. de Ferranti, the electrical engineers at Hollinwood, near Oldham, have just adopted an educational scheme for their apprentices. Success at evening classes, combined with steady work, are to be the chief recommendations for promotion from one department to another. And the apprentice who obtains the highest position in the South Kensington Examinations in subjects of importance to the theoretical training of an engineer will be awarded a scholarship tenable in the day engineering department of the Manchester Municipal Technical School. His fees will be paid by Messrs. Ferranti, and also the wages he would receive if working in their shops. Mr. F. Brocklehurst takes this generous scheme as the text of a pamphlet upon "Technical Education," issued by the Technical Instruction Committee of Manchester, and he hangs upon it some instructive remarks as to the responsibilities of manufacturers and the nation at large, if England is to maintain her position in the industrial world. Referring to education in Switzerland, he points out that at Winterthur, a small engineering town near Zurich, the technical school is attended by 400 day students who have voluntarily left their employment (sacrificing their wages in so doing) for one or two sessions in order to devote themselves to technical study. The town, the canton and the State combine to assist the realisation of their ambitions by bearing the burden of cost, and in keeping the fees of the technical school low. In the same way the great Polytechnic of Zurich is crowded in its day department with hundreds of young men preparing themselves for the engineering, electrical and chemical industries. Germany provides many similar examples. In the Technical High School of Darmstadt there are to be found 1100 day students, all of them over eighteen years of age, many of them graduates of universities, and the remainder having received a splendid high-class education in secondary schools. These are engaged in the study of electrical, chemical or mechanical science directly bearing upon industrial pursuits. This is only one of many technical high schools in Germany, the culmination of which is seen in the Charlottenberg Technical High School, near Berlin—the finest institution of its kind in the world—with its more than 2000 day students. These young men are being prepared for the highest positions, as technical chemists, mechanical, naval, civil and railway engineers, shipbuilders and architects. There are now in the German Technical High Schools no fewer than 11,000 day students. In connection with the figures given it must be noted that (1) they are exclusive of science students taking university courses; (2) the pupils are without exception youths of over eighteen years of age; and (3) each technical high school insists upon an entrance examination of an exacting character.

The great advance of the United States in engineering is, as Mr. Brocklehurst remarks in his pamphlet referred to above, largely due to the fact that during the last forty years very important engineering schools have been founded. The chief of these is the Massachusetts Institute of Technology at Boston. This is attended by 1171 day students, whose average age at entrance is eighteen years and nine months, and who are either graduates from other colleges or have attended the public high schools for at least four years. The Worcester Engineering Polytechnic has 823 day students. Nearly 1000 are in the Lehigh Engineering College. The Stevens Institute of Technology, New Jersey, has 214; and the Case School of Applied Science in Cleveland, Ohio, 218. Five hundred and ninety-seven day students attend the classes of the Sheffield Scientific School in Connecticut, while the Sibley College of Engineering—part of Cornell University, New York—has 492 day students. There are 242 day students in the Engineering Department of the University of Michigan. A recent report shows that in the Engineering Colleges of the United States the number of day students enrolled is 9659, and that their growth since 1878 is 516 per cent.! Fifty-one per cent. of these students have had a three-year high school course, which would bring them to seventeen years of age. The number of engineering students graduated in 1899 was 1413, and the number of institutions providing an education in this branch of technical instruction (engineering) is 89. This is exclusive of evening work altogether. It is also exclusive of what America is doing in the fields of chemistry and textiles. Little wonder is it that this wealth of educational opportunity is producing its crop of skilled craftsmen trained to compete on more than equal terms with the Briton. The Manchester Technical Institution Committee is doing a service to the nation by placing these facts prominently before the manufacturers of the district.

## SOCIETIES AND ACADEMIES.

### PARIS.

**Academy of Sciences,** August 27.—M. Faye in the chair.—On Egyptian gold, by M. Berthelot. Analyses of specimens of gold of different epochs show that at the time of the sixth and twelfth Egyptian dynasties the art of separating the silver from native gold was not known. Some gold leaf of the Persian epoch was pure, the silver having been separated. As, however, there is a period of about twelve centuries between the dates of the last two specimens analysed, specimens of intermediate dates must be examined if the date of this metallurgical discovery is to be fixed.—Observations of the comet 1900 *b* (Borelly-Brooks) made with the large equatorial of the Observatory of Bordeaux, by MM. G. Rayet and A. Férand. The nucleus of the comet on July 31 was of about the 9th or 10th magnitude, the head having a diameter of 3′ to 4′ of arc.—The apparent semi-diameter of the sun and its position relative to the moon, deduced from the eclipse of May 28, by MM. Ch. André and Ph. Lagrula. The final result for the apparent semi-diameter of the sun is given as $15' \, 59''\cdot24 \pm 0''\cdot30$.—On an anomaly of the dichotomous phase of the planet Venus, by M. E. Antoniadi. The edge of the planet is always more brilliant than the central regions; thence irradiation ought to produce the prolongations actually observed. The phenomenon would thus appear to be of purely physiological origin.—Dielectric cohesion and explosive fields, by M. E. Bouty. The term explosive field is applied to the minimum strength of field between two nearly plane electrodes required to produce sparking. The curves relating to critical fields, as described in a preceding note, show many analogies with those of explosive fields. Thus both the critical and explosive fields are linear functions of the pressure of the gas, and the constants for the gases hydrogen, air and carbonic acid are arranged in the same order of magnitude.—On the composition of the combinations obtained with fuchsine and the sulphonated azo-colouring matters, by M. Seyewetz.——On lighting by the cold physiological light called living light, by M. Raphael Dubois. By the growth of certain micro-organisms in suitable media, details of which are given, a room may be illuminated with an intensity about equal to moonlight.—Action of the total pressure upon the assimilation by chlorophyll, by M. Jean Friedel. Although the influence of the partial pressure of the carbon dioxide in the atmosphere upon chlorophyll assimilation has been well investigated, the effect of changing the total pressure of the air has not yet been examined. It was found that the lowering of the total pressure, even to $\frac{1}{4}$ atmosphere, does not modify the nature of the chlorophyll assimilation, but that its intensity diminishes in a regular manner with the pressure. Four species of plants were used, and the numbers obtained for the variations were of the same order in all of them.—On the ancient extent of the glaciers in the region discovered by the Belgian Antarctic Expedition, by M. Henryk Arctowski.

### CAPE TOWN.

**South African Philosophical Society,** August 1.—L. Péringuey, President, in the chair.—The secretary read a second report on the mud island which appeared off Pelican Point at the beginning of June, from Mr. Cleverly, R.M., Walfish Bay, and showed the photographs taken by Mr. Waldron, Public Works Department. Mr. Cleverly reported that the island no longer existed on June 7, it having then entirely subsided, as, on steaming over the site, soundings of six and seven fathoms were obtained. The sea was much discoloured, and a distinct odour of sulphur was still to be distinguished. Small quantities of dead fish were found on Pelican Point, but this is a not unusual occurrence. About the time of the island's appearance heavy rollers set in along the coast, and though these did not affect Walfish Bay, thirty yards of the new breakwater at Swakop Mouth were totally destroyed, a derrick carried away, and two men drowned. Though these rollers are usually experienced on this coast in the winter months, Mr. Cleverly understands that the engineer in charge at Swakop Mouth had set up a theory that the damage to his works resulted from an earthquake wave, and that he pointed to the appearance of the mud island at Walfish Bay in support of his theory, but in Mr. Cleverly's opinion the cause of the upheaval must have been extremely local as no disturbance whatsoever was felt at the settlement or in the confined waters of Walfish Bay. Mr. Waldron, on the invitation of the president, gave an account of his visits to the island. It was visited on June 1, 2 and 4. At the next visit, on June 7, there was no island. On June 1 one member of the party landed and noticed a small basin-shaped hollow containing water and emitting gas bubbles. The odour was distinctly that of sulphuretted hydrogen. Dr. Corstophine agreed with Dr. Marloth as to there being no need for volcanic activity to explain the phenomenon; nor was there any evidence of such. He compared the appearance of the island at Walfish Bay with the "mud lumps" known to arise in the Gulf of Mexico, and quoted Sir Charles Lyell's account of these. The Walfish Bay island was evidently a quite similar phenomenon. As to the gas, the Gulf of Mexico "mud lumps" usually gave off marsh-gas, and the sulphuretted hydrogen perceived as being emitted at Walfish Bay, was probably due to the decomposition of animal as against plant material. The fine mud from Walfish Bay, under the microscope, was found to contain diatoms, fish scales, bones, and other remnants of animal matter.—Notes on stone implements of palæolithic type found at Stellenbosch and the vicinity, by L. Péringuey and G. S. Corstophine. The discovery of stone implements of a particularly ancient type at Bosman's Crossing, Paarl and Malmesbury, was described. From the rude character of the chipped stones, Mr. Péringuey was disposed to regard them as being equal in age to the palæolithic implements of Europe, but Dr. Corstophine had shown him the difficulty of accepting this theory owing to the geological deposits in or on which the stones are found. So far no implements have been found in any deposit that can be regarded as of great antiquity. In the Stellenbosch district the implements are found imbedded either in the rain-wash of weathered granite or in the laterite, or simply on the surface, so that no geological evidence has yet been discovered as to the presumable antiquity of the implements. One feature of this occurrence, which Dr. Corstophine pointed out, is that as yet no implements have been found on the recent alluvial terraces of the Eerste River, but only on the hill slopes round about. The implements are formed from water-worn boulders of Table Mountain Sandstone, and often retain a considerable portion of the water-worn surface.

THURSDAY, SEPTEMBER 13, 1900.

## BACTERIOLOGY.

*The Structure and Functions of Bacteria.* By Alfred Fischer, Professor of Botany at the University of Leipzig. Translated into English by A. Coppen Jones. Pp. viii + 198. (London: Clarendon Press, 1900.)

THE first two chapters are concerned with the morphology of bacteria, and the subject is most ably dealt with, as might be expected from so talented a botanist as Prof. Fischer. Nevertheless, these are not the chapters which strike one as of exceptional interest or importance, because they treat of matters discussed in every text-book of bacteriology, and afford but little new information.

Chapters iii. and iv., under the title of "Taxonomy," deal with the question of species and variability among bacteria; the involution and attenuation of microbes; the systematic position of bacteria and their classification. Prof. Fischer points out that the heated controversy on the "species question" rests on our different conception of *pleogony* and *pleomorphism* among bacteria. Pleomorphism in its true sense does not exist among bacteria according to Fischer, and mutability of function (other than of a temporary character) is also denied by him. Thus he asserts positively that "It has not been hitherto possible to entirely suppress a single biological character in any species." We are inclined to take a less dogmatic position as regards the *suppression* of a biological character, while fully agreeing with the author that the attainment in our cultures of *acquired* characters that are permanent and hereditary in bacteria is not to be expected. The classification of bacteria proposed by Fischer has much to commend it, but it is natural to shrink from so sweeping a change in our existing nomenclature as would be necessary if his views were universally adopted. The tetanus bacillus, according to Fischer, would fall under the genus Plectridium, the sub-family Plectridiæ, the family Bacillaceæ, and the order Haplobacterinæ. The typhoid bacillus would come under the same order, but the genus would be Bactridium, the sub-family Bacilleæ, and the family Bacillaceæ.

Fischer suggests that

> "the names of the genera might be formed conveniently in such a way that the root of the word indicated the shape of the cell, and the termination the arrangement of the cilia. The root-words might be *baktron* (rod), *kloster* (spindle), and *plectron* (drum-stick), and the terminations *-inium* for monotrichous, *-illum* for loptotrichous, and *-idium* for peritrichous types."

Chapter v. deals with the distribution of bacteria; their modes of life, and spontaneous generation. Using the modes of nutrition as a basis for classification, Fischer divides bacteria into the following groups:—

### I. *Prototrophic Bacteria.*

Nitrifying bacteria, bacteria of root-nodules, sulphur and iron bacteria, occur only in the open in nature—never parasitic, always monotrophic.

### II. *Metatrophic Bacteria.*

Zymogenic, saprogenic and saphrophile bacteria occur in the open and upon the external and internal surfaces of the body—sometimes parasitic (facultative parasites), monotrophic or polytrophic.

### III. *Paratrophic Bacteria.*

Occur only in the tissues and vessels of living organisms—true (obligatory) parasites.

The author remarks that it is worthy of note that not only the bacteria but all other organisms can be arranged in these three biological divisions.

Chapters vi. to ix. deal with the physiology of nutrition, general principles of culture, respiration of bacteria, influence of physical agents, and the action of chemicals. It is impossible in the limits of this review to do justice to these chapters, which although treating of matters described in every text-book of bacteriology, yet succeed in presenting the subject to the reader in a new and attractive light.

Chapters x. and xi. treat of the circulation of nitrogen in nature. It may be said without fear of contradiction that the author has dealt with this complex problem in a masterly manner. No other writer that we are aware of (unless, perhaps, Lafar) has placed the subject before the reader in so comprehensive and intelligible a form. To indicate the scope of these chapters we cannot forbear quoting from the introductory remarks as follows:—

> "Apart from the activity of organisms like the pigment and phosphorescent bacteria, and other remarkable metabolism of the sulphur—and iron—bacteria, the work of bacteria in nature embraces three great processes:
>
> (1) The circulation of nitrogen: effected by putrefaction, the formation of nitrates, and the assimilation of atmospheric nitrogen.
>
> (2) The circulation of carbon by the fermentation of carbohydrates and other non-nitrogenous products of animals and plants.
>
> (3) The causation of disease in other organisms, particularly in man and the higher animals.
>
> There are in nature five sources of nitrogen open to plants and animals:
>
> (1) The atmosphere (79 per cent. by volume of free nitrogen).
>
> (2) The nitrates of the soil and the traces of nitrous acid formed in the air during thunderstorms.
>
> (3) Ammonia, which occurs in minute quantities in the air, and is set free abundantly by the putrefaction and decay of dead organisms.
>
> (4) Animal excreta, which contains nitrogen compounds of many kinds, even down to ammonia; and
>
> (5) The tissue of plants and animals."

Chapters xii. to xiv. deal with the circulation of carbon dioxide in nature, and they are full of interest to the biologist, and will doubtless appeal very strongly to students of agricultural chemistry.

Chapters xv. to xvii. treat of bacteria in relation to disease. In no captious spirit we venture to offer the criticism that here the author treads on less familiar ground, and although the subject is discussed in a scholarly and instructive manner, there is some evidence that a pure botanist is apt to fall into error when invading the domain of the pathologist. We do not agree with the author when he says that *B. coli* is almost indistinguishable from the parasite of typhoid fever. It is easily distinguished—the difficulty lies in differentiating between certain phase-forms or allies of *B. coli* and the typhoid germ. Again, Prof. Fischer would seem to be in error when he says that the dimensions of the two are about the same, that both are actively motile and peritrichously ciliated, and that the cilia are too delicate for their number to be of determinative value. As a matter of fact, *B. coli* is a short rod, hardly longer than broad, frequently showing only very feeble motility, and usually having only 1 to 3 flagella, which stain with difficulty; whereas the typhoid bacillus occurs as long, thin, slender rods and filaments, which (the rods) are actively motile and move about in a fashion quite different from the colon bacillus. Moreover, the flagella average ten in number, and stain readily. The statement that *B. coli* is frequently present in dirty water must be accepted with reserve, unless it be assumed that the word "dirty" is meant by the author to convey the idea of fouling with matter of an excremental sort. Again, the author, speaking of the staphylococci (s.p. aureus, citreus and albus), says that in nature these germs are found everywhere. We venture to dispute the truth of this remark, which is stated as if it were a fact; yet in our judgment it is merely a supposition, and an erroneous one.

These few criticisms are made in no carping spirit; indeed, the book as a whole strikes us as being one of the best that has been written on the subject, and in many respects it is quite unique. The chapters dealing with the circulation of nitrogen and carbon in nature are altogether admirable. We can find no words sufficiently strong to recommend this book to the perusal of all students of bacteriology, and particularly to those interested in biology from the technical point of view.

Unstinted praise must be given to the translator; in offering to English readers a translation of Prof. Alfred Fischer's "Vorlesungen über Bakterien" he has placed us under a deep debt of gratitude. A. C. HOUSTON.

## OUR BOOK SHELF.

*A Walk Through the Zoological Gardens.* By F. G. Aflalo, F.R.G.S., F.Z.S. Pp. 232. (London: Sands and Co., 1900.)

IT is not by any means abundantly clear that a guide to the Zoological Society's Gardens is needed, inasmuch as there already exists the well-known and accurate guide to the Society's collection by Mr. Sclater. Although it is true that the author does not call his book a "guide" in the title, he nevertheless observes in the preface that it is his object "to conduct the reader from house to house and from paddock to paddock, pointing out the chief features of interest" on the way. We must, therefore, consider the book as intended to be a guide. As such it does not appear to us to be at all informing; it would have been well, too, to avoid positive error. The author calls a sea-lion a seal, which—seeing that true seals are often exhibited—is confusing. The African Mudfish, *Protopterus*, often on view in the Reptile house, is dubbed *Lepidosiren*, which, we need scarcely explain, is a South American Dipnoan. There are other errors of fact, and certain statements which are so loose and confused that they are practically erroneous. It is naturally impossible in a small book like the present to give an exhaustive account of all the animals to be seen in the course of a year or two in the Gardens. But the author leaves out so many important beasts that he fails to convey a real notion of the extent and variety of the collection. By cutting out the tale of how he rescued a blue pencil from a cormorant, which afterwards swallowed a lady's parasol, and by forbearing to mention that porcupines "pare their teeth on elephants' tusks" (!), and generally by avoiding gossip of a totally uninteresting and equally uninstructive kind, Mr. Aflalo might have grappled more successfully with the immense amount of material at his disposal.

## LETTER TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

### The Reform of Mathematical Teaching.

To your issue of August 2 Prof. Perry contributes an indictment of the present system of mathematical teaching in this country. As he invites criticism, one need not apologise either for defending existing methods or for criticising his suggested improvements. His main attack seems to be directed against mathematics as an educational subject, and in particular the teaching of Euclid falls under his ban. The elements of abstract reasoning are, he says, quite unnecessary to a boy's mental development. Why does he not add that common-sense is of no value also?

Do we always first learn by actual trial, as is stated in his article? Do we throw ourselves into deep water and learn to swim forthwith? Do we set about jumping, cycling, billiards or cards without any previous explanation? Surely, as a rule, in these matters we are taught, not only what to do at the start, but also, if we can grasp them, the guiding principles. In a game of whist, who does not dread the unreasoning partner who has learnt the rule "Third player plays highest," and blindly acts upon it?"

Euclid, though it might advantageously be shortened by the assumption of a few more axioms and postulates, is not, I venture to say, at all a "soul-destroying, weary, worrying study for the schoolboy." Of course it may be made so, but to every boy, with care, it may become interesting, and, in the experience of many teachers, it proves a more engrossing subject to their classes than either arithmetic or algebra.

Prof. Perry very properly points out some of the weak spots in present-day arithmetic. He instances "our abominable system of weights and measures." One may suggest that that system is hardly the fault of our system of mathematics; it is entirely its misfortune. Will he not, instead of girding at the unfortunate teachers of mathematics, agitate for a conference of delegates from all bodies interested in this most important question?

Later on in his article it is stated that practice, interest, discount, tare and tret, alligation, position, &c., are at this day taught exactly as during the last century. This statement is absurd.

It is true that discount, percentages, stocks, areas, &c., are all dependent on the rule of proportion; but for purposes of explanation and of interest it is certainly as well not to lump these together in one heterogeneous muddle under the head of "Proportion." If such a method were in vogue, or if the whole of arithmetic were, by means of formulæ, reduced to multiplication and division, one would certainly see "the film of dulness covering a boy's face as he entered the class-room."

As regards the syllabus quoted by Prof. Perry, it is easy to agree with him thus far—that it is admirably adapted for a *technical* training. In practical mathematics, where mental training is of minor importance, exigencies of time will compel the teacher to omit explanations, or only to give them roughly, for his chief object is to enable his pupils to apply mathematical results, as distinct from reasoning, to problems in engineering, science, or kindred subjects.

On the other hand, the average boy's mathematical education up to the age of fifteen or sixteen is an absolutely different matter; to put it crudely—the teacher's main effort is to enable his pupil to ask and to answer reasonably the question "Why?"

At present there is really no orthodox system, but, in my opinion, the methods enunciated in the principal text-books of the day do, with slight exceptions, tend to develop a boy's mental powers.

When the boy has decided on his profession, then by all means continue his education on the lines suggested by Prof. Perry.

Finally (if one may misquote his opening words), "it is very important to try to get a view of our system of teaching mathematics, which is not too much tinted with pleasant (or possibly unpleasant) memories of science and engineering."

W. F. BEARD.

## *SIR JOHN BENNET LAWES, BART., F.R.S.*

ONE of our truly great men has passed away. Born in 1814, his life extended over the greater part of a century full of great men and great deeds; yet among this goodly company he will surely be placed in the front rank if we have regard to his personal qualities, and to the far-reaching and beneficial character of his achievements. An only son, he was left at the age of eight without a father, and owed much of his bringing up to the care of his mother, to whom he was extremely attached. Educated at Eton and Oxford, he entered in 1834, at the age of twenty, on the management of the paternal estate at Rothamsted, Herts. How many youths placed thus early in the possession of a beautiful home, and a sufficient income, would have fallen into habits of easy enjoyment, and left nothing behind them worth recording? But these circumstances, so full of danger to the average lad, were exactly suited for the development of the work which the youthful squire was to accomplish. His active mind obtained at once perfect freedom of action. His love of work and high sense of duty led him to devote himself to the management of the home farm, and under his keen observation its fields became to him pages of nature, which year by year told him new facts, answered new questions, and revealed fresh wonders.

In boyhood Sir John Lawes had somehow imbibed a taste for chemistry. He has told in his own graphic way how he delighted to write with a stick of phosphorus on the door of a dark room, and to give electric shocks to the old housekeeper. On taking up his residence at Rothamsted he proceeded to fit up one of the bedrooms as a laboratory and commenced a variety of experiments. Chemistry was at that time to a large extent a department of medical science, and some of his earliest work was directed to the isolation of the alkaloids of medicinal plants. The manufacture of calomel by a new process—the combustion of mercury in chlorine gas—also engaged his attention; an old barn was converted into a laboratory, and the process carried out for some time on a commercial scale. We have here his first decided step as a chemical manufacturer.

Three or four years elapsed before any experiments were made on agricultural subjects. In 1837 Sir John Lawes commenced growing plants in pots with various substances applied as manure, and more numerous experiments of this kind were carried out in the two following years. His attention had been drawn to the uselessness of bones when applied as a manure to turnips on heavy soils, although they proved extremely effective on light soils. He tried treating fresh bone and burnt bone with sulphuric acid, and speedily remarked the great increase in the manurial effect of the bone so treated. Mineral phosphates, as apatite, were treated with sulphuric acid, and were also found to yield a most effective manure. The value of these acidified manures having been confirmed by trials in the field, both at Rothamsted and elsewhere, it became evident that a fact of the greatest importance to agriculture had been discovered. The farmer was no longer dependent on bone or guano for a supply of phosphate, the vast deposits of phosphatic rocks and minerals were equally available for his use, and could be converted into a potent manure by treatment with sulphuric acid; moreover, the new manure was as effective upon heavy as upon light land.

In 1842 Sir John Lawes took out his patent for treating apatite and other phosphatic minerals with sulphuric acid, thus producing superphosphates. This event laid the foundation of the vast manufacture of artificial manures which now supplies the varied wants of the farmer, and enables him to restore or increase the fertility of his land in the most effective and economical manner. At the present time the annual production of superphosphates in the United Kingdom reaches the enormous total of 900,000 tons! In other countries the quantities manufactured are equally prodigious. The influence of these manures on the productiveness of the soil in civilised countries is incalculable.

It was a serious step for a young country squire to start a large manure factory, and to enter himself as a wrestler in the keen competitions of commercial life. The difficulties which beset a successful, rapidly growing business are especially great, as the continually increasing demand for capital more than swallows up the accruing profits. But the owner of Rothamsted had already developed his mental powers. His cool head, his quick grasp of a situation, his methodical habits, his enterprising spirit, and his scientific training made him a most successful man of business. In 1843 a manure factory was started by Sir John Lawes at Deptford Creek. In 1857 the business had so increased that 100 acres of land were purchased at Barking Creek, and a much larger and more complete plant erected. The whole of the manure business was sold in 1872 for 300,000*l*.

Having entered upon London commercial life, Sir John Lawes did not confine his enterprise to the production of manures; his activity was displayed in many directions. In 1867 a large factory at Millwall for the production of tartaric and citric acid was acquired. Here the same tale has to be told as that relating to the manure business. The scientific enterprise of the new owner, his carefulness for economy of production, and the advantages he obtained from command of capital, soon placed him also at the head of this branch of English chemical manufacture.

We need not in this place refer at greater length to Sir John Lawes' commercial career, which continued with activity up to his death; it has been due to the man to depict the results of this large portion of his life's work, and also to note the remarkable character which he obtained in the commercial world. His enterprise and command of capital made him at all times a formidable competitor; but his name was still better known as associated with scrupulous fairness of dealing, and in cases of difficulty it became recognised that it was better to trust to Sir John Lawes' generosity than to fight for individual rights.

One might readily suppose that the commercial life of such a successful man of business would have engrossed nearly the whole of his time and energy; this was far from being the case. The wonder of the man was that he carried on so long and so successfully a dual life. He seemed to have the power of putting aside at once all one class of thoughts and interests, and of embarking with perfect freshness and enthusiasm on another subject; and of all subjects, agriculture, chiefly regarded as presenting a series of problems in agricultural chemistry, was the one in which his greatest interests were centred. Business might occupy his mind, but agriculture was always the mistress of his heart. This would appear in a striking manner in the midst of his London work. On the occasion of his weekly visit to the chemical laboratory at Millwall, a very few minutes would generally suffice for the despatch of immediate business, and Sir John Lawes would then frequently spend an hour in eloquent talk with the writer of the present notice upon the agricultural problems which then most interested him. Visitors to the Rothamsted experiments might well be ignorant of the existence of the vast London business. The spirit of the counting-house never invaded Rothamsted; here the experimental fields, and the reports preparing on the results they yielded, seemed to engage his whole attention. No one knew the fields as well as he did, and an afternoon spent at home generally included a walk, spud in hand, through the whole of them.

For the sake of clearness in our narration, we have brought together in one view the principal facts relating to Sir John Lawes' career as a chemical manufacturer; we have next to regard him as the founder of the Agricultural Experiment Station at Rothamsted, and as its presiding genius during a period of nearly sixty years.

We must go back again to 1842. When Sir John Lawes had taken out his patent, and had determined to start a factory in London, it would have seemed natural if his entire energies had been transferred to this new and promising sphere of labour; but now the truly scientific character of the man was made manifest. The agricultural investigations in the fields at Rothamsted, which had become so fascinating, were not to be given up, but extended. This could only be done by engaging scientific assistance. A young chemist, Dr. J. H. Gilbert, was engaged to superintend the Rothamsted experiments; and thus, in 1843, began that partnership in labour which has yielded such a rich harvest of results.

The station thus founded at Rothamsted began its work long before any of the agricultural stations now existing in other countries, of which there are at present several hundreds. The investigations carried out have proceeded to a considerable extent on lines peculiar to the place, and have generally been of a very laborious character. The most striking characteristic of Rothamsted is its experimental fields, covering nearly forty acres. Here the various crops of a four-course rotation are grown, both separately and in their usual order of succession; the influence of different manures upon the quantity and composition of the crops is studied; the alterations in the composition of the soil brought about by different treatment are determined, and in some cases the composition of the drainage water from the different plots is ascertained. The Rothamsted investigations have also included many important and laborious experiments on farm animals.

It is quite impossible to attempt to enumerate the various investigations made at Rothamsted. The first formal report appeared in 1847. The collected reports now occupy nine volumes. We may, however, note some stages in the development of this great enterprise. By 1848 most of the experimental fields had commenced their work; by 1856 the whole of the present series was in operation. The chemical work required soon exceeded the capacity of the old barn first used, and in 1854–5 a handsome new laboratory was built and presented to Sir John Lawes as a testimonial from the agriculturists of England for his services to agriculture. Large additional buildings for preparing and storing samples have since been added. In 1889 Sir John Lawes transferred the whole of the laboratories and experimental fields to trustees, with an endowment of 100,000*l.*, so that the agricultural investigations might be permanently continued. The management is now vested in a committee, nominated by the Royal, the Royal Agricultural, the Chemical and the Linnean Societies. The jubilee of the Rothamsted Station was celebrated in 1893, and on this occasion Dr. J. H. Gilbert received the honour of knighthood. A full account of the celebration will be found in NATURE of July 27 and August 3, 1893.

But we must turn once more to the man himself. Sir John Lawes received many honours. The Queen created him a baronet in 1882. Universities gave him their degrees; societies bestowed upon him their medals. Prosperity could not spoil him. Quite free from personal ambition, he was always ready to give the credit of success to his fellow-workers. Visitors to the Rothamsted experiments—and they were many—were delighted when Sir John himself was the pilot of the party; the two hours' talk to which they listened was a treat to be remembered. In terse, vigorous sentences the practical results of each trial were brought before them, while the whole was illuminated by many a flash of humour. In his middle life Sir John Lawes wrote a great number of short articles for the agricultural press. In these he excelled. His thorough knowledge of the details of farming, and his practical mind, prevented him from ever writing as a mere doctrinaire; the facts ascertained by investigation were presented by him in their concrete aspect as things to be reckoned with by the farmer in his daily life on the farm.

Our notice would be incomplete without some reference to his local beneficence. As Lord of the Manor he did much to maintain and increase the charms of a pretty village now rapidly transforming itself into a town. He was the agricultural labourers' best friend. He provided them with an ample supply of allotment gardens, and in 1857 built a club room for their benefit; this was visited and described by Charles Dickens in 1859. Sir John Lawes also tried to introduce several co-operative schemes for the labourers' benefit. He was always seen to great advantage on the occasion of the annual allotment club dinner at which he presided, when he carved a huge piece of beef provided by himself, and afterwards made a humorous speech to the labourers. As a generous donor to public and private charities he will be long remembered.

As he passed into old age his powers seemed to suffer little diminution. A few days before his last illness he went as usual to London, and thence down to the factory at Millwall. He died on August 31, in his eighty-sixth year, full of days and full of honours, and venerated by all who knew him.

R. WARINGTON.

## THE BRADFORD MEETING OF THE BRITISH ASSOCIATION.

IN the midst of the turmoil of the Association week it is difficult to give any careful compression of the results of the meeting; but, from the point of view of the Local Committee, the visit has been an unqualified success. Apprehensions were felt, in making the preliminary arrangements, lest there might be some incongruity in certain cases between the guests and the hosts: but, judging from the absence of rumours to that effect, the fears were groundless.

One point upon which at first some individual soreness arose was due to a slight misunderstanding in the matter of the excursions. These had long presented an exceedingly difficult problem to the local organisers of Association meetings; so much so, that the entire abandonment of all excursions has at times been contemplated. It is probably inevitable that, in any scheme put forward to ensure the success of the excursionists as a whole, some individual hardship must be occasioned, leading to a certain amount of unpleasantness. In the circumstances, it is scarcely surprising that, at first, a few sufferers should have complained that the excursion arrangements had been planned in a new and inferior manner; but, eventually, they fell in readily with the innovations. At former meetings it has been found impossible to organise excursions upon any exact system, owing to the fact that persons applied for tickets in a vague and undecided spirit, and often failed to take them up when they were allotted to them, to the consequent deprivation of other persons. Accordingly, in the Bradford scheme, the following regulations were issued:—

(1) That out of the seven excursions for the day three should be selected in the order of preference. (2) That the fee (made practically uniform) should be handed in with the application form; and (3) that persons complying with these requirements should in due course receive a ticket for one of the trips selected, or have their money returned. Those applicants who stated that they would only name a single excursion were

advised not to hand in any application or fee, as no guarantee could be given that they would receive one particular ticket. Despite the individual irritation which has been occasioned by an imperfect comprehension of the scheme, and by occasional unwillingness to comply with the conditions, the new arrangement has received a widespread approval, and has formed another instance of the willing and courteous acceptance of the Bradford arrangements, which has so conspicuously characterised the present meeting of the Association.

RAMSDEN BACCHUS.

### *Meetings of the General Committee.*

At the first meeting of the General Committee, Prof. Schäfer reported that the following resolutions had been considered and acted upon by the Council of the Association.

I. That in view of the opportunities of ethnographical inquiry which will be presented by the Indian census, the Council of the Association be requested to urge the Government of India to make use of the census officers for the purposes enumerated below, and to place photographers at the service of the census officers :—(1) To establish a survey of the jungle races, Bhils, Gonds, and other tribes of the central mountain districts ; (2) to establish a further survey of the Naga, Kuki, and other cognate races of the Assam and Burmese frontiers ; (3) to collect further information about the vagrant and criminal tribes, Haburas, Beriyas, Sansiyas, &c., in North and Central India ; (4) to collect physical measurements, particularly of the various Dravidian tribes, in order to determine their origin ; and of the Rajputs and Jats of Rajputana and the Eastern Punjab, to determine their relation with the Yu-echi and other Indo-Scythian races ; (5) to furnish a series of photographs of typical specimens of the various races, of views of archaic industries, and of other facts interesting to ethnologists.

II. That the Council be requested to represent to Her Majesty's Government the importance of giving more prominence to botany in the training of Indian forest officers.

A resolution was adopted, that in future women should be eligible as members of the Sectional Committees.

At the second meeting of the General Committee it was decided that the meeting of the Association in 1902 should be held in Belfast. The meeting next year will be held in Glasgow, with Prof. A. W. Rücker as president, and will commence on Wednesday, September 11, 1901. The vice-presidents for the meeting will be: The Earl of Glasgow, Lord Blythswood, Lord Kelvin, the Lord Provost of Glasgow, the Principal of the University of Glasgow, Sir John Stirling-Maxwell, M.P., Sir Andrew Noble, Sir Archibald Geikie, Sir W. T. Thiselton-Dyer, Mr. James Parker Smith, M.P., Mr. John Inglis, and Mr. Andrew Stewart. Alluding to the arrangements for the Glasgow meeting, the Lord Provost of Glasgow said the University had been placed at the disposal of the Association, and all the Sections will probably be accommodated under one roof. There will also be an exhibition in Glasgow next year, and the 450th anniversary of the University will be celebrated.

Prof. Schäfer has retired from his position as one of the general secretaries, and Dr. D. H. Scott has been elected his successor.

The following is a synopsis of the grants of money appropriated to scientific purposes by the General Committee :—

## SECTION A.

### DEPARTMENT OF ASTRONOMY.

OPENING ADDRESS BY DR. A. A. COMMON, F.R.S., F.R.A.S., CHAIRMAN OF THE DEPARTMENT.

IT has been decided to form a Department of Astronomy under Section A, and I have been requested to give an address on the occasion. In looking up the records of the British Association to see what position Astronomy has occupied, I was delighted to find, in the very first volume, "A Report on the Progress of Astronomy during the Present Century," made by the late Sir George Airy, so many years our Astronomer Royal, and at that time Plumian Professor of Astronomy at Cambridge. This report, made at the second meeting of the Association, describes, in a most interesting manner, the progress that was made during the first third of the century, and we can gather from it the state of astronomical matters at that time. The thought naturally occurred to me to give a report, on the same lines, to the end of this century, but a little consideration showed that it was impossible in the limited time at my disposal to give more than a bare outline of the progress made.

At the time this report was written we may say, in a general way, that the astronomy of that day concerned itself with the position of the heavenly bodies only, and, except for the greater precision of observation resulting from better instruments and the larger number of observatories at work, this, the gravitational side of astronomy, remains much as it was in Airy's time.

What has been aptly called the New or Physical Astronomy did not then exist. I propose to briefly compare the state of things then existing with the present state of the science, without dealing very particularly with the various causes operating to produce the change; to allude briefly to the new astronomy; and to speak rather fully about astronomical instruments generally, and of the lines on which it is most probable future developments will be made.

In this report (*Brit. Assoc. Report*, 1831–32, p. 125) we find that at the beginning of the century the Greenwich Observatory was the only one in which observations were made on a regular system. The thirty-six stars selected by Dr. Maskelyne, and the sun and moon, were observed on the meridian with great regularity, the planets very rarely and only at particular parts of their orbits; small stars, or stars not included in the thirty-six, were seldom observed.

This state of affairs was no doubt greatly improved at the epoch of the report, but it contrasts strongly with the present work at Greenwich, where 5000 stars were observed in 1899, in addition to the astrographic, spectroscopic, magnetic, meteorological, and other work.

Many observatories, of great importance since, were about that time founded, those at Cambridge, Cape of Good Hope and Paramatta having just been started. A list is given of the public observatories then existing, with the remark that the author is "unaware that there is any public observatory in America, though there are," he says, "some able observers."

The progress made since then is truly remarkable. The first public observatory in America was founded about the middle of the century, and now public and private observatories number about 150, while the instrumental equipment is in many cases superior to that of any other country. The prophetic opinion of Airy about American observers has been fully borne out. The discovery of two satellites to Mars by Hall in 1877, of a fifth satellite to Jupiter by Barnard in 1892, and the discovery of Hyperion by Bond, simultaneously with Lassell, in 1848, are notable achievements.

The enormous amount of work turned out by the Harvard Observatory and its branches in South America, all the photographic and spectroscopic work carried out by many different astronomers, and the new lines of research initiated show an amount of enthusiasm not excelled by any other country. A greater portion of the astronomical work in America has been on the lines of the new astronomy, but the old astronomy has not been at all neglected. In this branch pace has been kept with other countries.

From this report we gather that the mural quadrant at most of the observatories was about to be replaced by the divided circle. Troughton had perfected a method of dividing circles, which, as the author says, "may be considered as the greatest improvement ever made in the art of instrument making."

Two refractors of 11 and 12 inches aperture had just been imported into this country; clockwork for driving had been applied to the Dorpat and Paris equatorials, but the author had not seen either in a state of action.

The method of mounting instruments adopted by the Germans was rather severely criticised by the author, the general principle of their mounting being "telescopes are always supported at the middle, not at the ends."

"Every part is, if possible, supported by counterpoises."

"To these principles everything is sacrificed. For instance, in an equatorial the polar axis is to be supported in the middle by a counterpoise. This not only makes the instrument weak (as the axis must be single), but also introduces some inconvenience into the use of it. The telescope is on one side of the axis; on the other side is a counterpoise. Each end of the telescope has a counterpoise. A telescope thus mounted must, I should think, be very liable to tremor. If a person who is no mechanic and who has not used one of these instruments may presume to give an opinion, I should say that the Germans have made no improvement in instruments except in the excellence of the workmanship."

I have no doubt that this question had often occupied Airy's mind, for in the Northumberland Equatorial Telescope which he designed shortly after for Cambridge he adopted what has been called the English form of mounting, where the telescope is supported by a pivot at each side, and a long polar axis is supported at each end. This telescope is in working order at the present time at Cambridge.

When he became Astronomer Royal he used the same design for what was for many years the great equatorial at Greenwich, though the wooden uprights forming the polar axis were in the Greenwich telescope replaced by iron. It says much for the excellence of the design and workmanship of this mounting, designed as it was for an object-glass of about 13 inches diameter, when we find the present Astronomer Royal, Mr. Christie, has used it to carry a telescope of 28 inches aperture, and that it does this perfectly.

Notwithstanding the greater steadiness of the English form of mounting, the German form has been adopted generally for the mounting of the large refractors recently made.

There is much interesting matter in this report of an historical character.

As I have already said, the new astronomy, as we know it, did not exist; but in a report (*Brit. Assoc. Report*, 1831–32, p. 308) on optics, in the same volume, by Sir David Brewster, we find that spectrum analysis was then occupying attention, and the last paragraph of this report is well worth quoting: "But whatever hypothesis be destined to embrace and explain this class of phenomena, the fact which I have mentioned opens an extensive field of inquiry. By the aid of the gaseous absorbent we may study with the minutest accuracy the action of the elements of material bodies in all their variety of combinations, upon definite and easily recognised rays of light, and we may discover curious analogies between their affinities and those which produce the fixed lines in the spectra of the stars. The apparatus, however, which is requisite to carry on such inquiries with success cannot be procured by individuals, and cannot even be used in ordinary apartments. Lenses of large diameter, accurate heliostats, and telescopes of large aperture are absolutely necessary for this purpose; but with such auxiliaries it would be easy to construct optical combinations, by which the defective rays in the spectra of all the fixed stars down to the *tenth* magnitude might be observed, and by which we might study the effects of the very combustion which lights up the suns of other systems."

Brewster's words are almost prophetic, and it would almost appear as if he unknowingly held the key to the elucidation of the spectrum lines, for it was not until 1859 that Kirchhoff's discovery of the true origin of the dark lines was made.

Fraunhofer was the first to observe the spectra of the planets and the stars, and to notice the different types of stellar spectra. In 1817 he recorded the spectrum of Venus and Sirius, and later, in 1823, he described the spectrum of Mars; also Castor, Pollux, Capella, Betelgeux and Procyon.

Fraunhofer, Lamont, Donati, Brewster, Stokes, Gladstone and others carried on their researches at a time when the principles of spectrum analysis were unknown, but immediately upon Kirchhoff's discovery great interest was awakened.

With spectrum analysis thus established, aided as it was later by the greater development of photography, the new astronomy was firmly established.

The memorable results arrived at by Kirchhoff were no sooner published than they were accepted without dissent. The works of Stokes, Foucault and Ångström at that period were all suggestive of the truth, but do not mark an epoch of discovery.

Astronomical spectroscopy divided itself naturally into two main branches, the one of the sun, the other of the stars, each having its many offshoots. I shall just mention a few points relating to each. The dark lines in the solar spectrum had already been mapped by Fraunhofer, and now it only needed better instruments and the application of laboratory spectra with Kirchhoff's principle to advance this work still further.

Fraunhofer had already pointed out the way in using gratings, and these were further improved by Nobert and Rutherfurd.

Kirchhoff's Map of the Solar Spectrum, published in 1861–62, was the most complete up to that time; but the scale of reference adopted by him was an arbitrary one, so that it was not long before this was improved upon. Ångström published in 1868 his map of the "Normal Solar Spectrum," adopting the natural scale of wave-lengths for reference, and this remained in use until quite recent times.

The increased accuracy in the ruling of gratings by Rutherfurd materially improved the efficiency of the solar spectroscope, but it was not until Prof. Rowland's invention of the concave grating that this work gained any decisive impetus. The maps (first published in 1885) and tables (published in the years 1896–98) of the lines of the solar spectrum are now almost universally accepted and adopted as a standard of reference. These tables alone record about 10,000 lines in the spectrum of the sun, which is in marked contrast to the number 7 recorded by Wollaston at the beginning of the century (1802). Good work in the production of maps has also been done in this country by Higgs.

Michelson has also recently invented a new form of spectroscope called the "Echelon" (*Ast. Phys. Journ.*, vol. viii. 1898, p. 37), in which a grating with a relatively small number of lines is employed, the dispersion necessary for modern work being obtained by using a high order (say the hundredth) into which most of the light has been concentrated.

Besides lines recorded in the visual and ultra-violet portions of the solar spectrum, maps have been made of the lines in the infra-red, the most important being that of Langley's, published in 1894, prepared by the use of his "bolometer." Good work had, however, been done in this direction previously by Becquerel, Lamansky and Abney; the last, indeed, succeeded even in photographing a part of it.

The recording of the Fraunhofer lines in the solar spectrum is not all, however. The application of the spectroscope to the sun has several epoch-marking events attached to it, notably those of proving the solar character of the prominences and corona, the rendering visible of the prominences without the aid of an eclipse by the discovery of Lockyer and Janssen in 1868, the photography of the prominences both round the limb and those projected on the solar disc by the invention of the spectraheliograph by Hale and Deslandres in 1890.

Success has not yet favoured the many attempts to photograph the corona without an eclipse by spectroscopic means; but even now this problem is being attacked by Deslandres with the employment of the calorific rays.

Spectroscopic work on the sun has led to the discovery of many hundreds of dark lines, the counterparts of which it has not yet been possible to produce on the earth.

But besides those unknown substances which reveal their presence by dark lines, there were two others discovered, which showed themselves only by bright lines, the one in the chromosphere, to which the name of Helium was given, and the other in the corona, to which the name of Coronium was applied.

The former was, however, identified terrestrially by Ramsay in 1895, though the latter is still undetermined. The revision of its wave-length, brought about by the observations of the eclipse of 1898, may, however, result in this element being transferred from the unknown to the known in the near future.

The study of stellar spectra was taken up by Huggins, Rutherfurd and Secchi. Rutherfurd (*Am. Journ.*, vol. xxxv. 1862, p. 77) published in 1862 his results upon a number of stars, and suggested a rough classification of the white and yellow stars; but Secchi deserves the high credit of introducing the first systematic differentiation of the stars according to their spectra, he having begun a spectroscopic survey of the heavens for the purposes of classification (*Comptes rendus*, t. lvii. 1853), whilst Huggins devoted himself to the thorough analysis of the spectra of a few stars.

The introduction of photography marks another epoch in the study of stellar spectra. Sir William Huggins applied photography as early as 1863 (*Phil. Trans.*, 1864, p. 428), and secured an impression of the spectrum of Sirius, but nearly another decade elapsed before Prof. H. Draper (*Am. Journ. of Soc. and Arts*, vol. xviii. 1879, p. 421) took a photograph of the spectrum of Vega in 1872, which was the first to record any lines. With the introduction of dry plates this branch of the new astronomy received another impetus, and the catalogues of stellar spectra have now become numerous. Among them may be mentioned those of Harvard College, Potsdam, Lockyer, McClean and Huggins. The Draper Catalogue (*Annals Harvard Coll.*, vol. xxvii. 1890) of the Harvard College, which is a spectroscopic Durchmusterung, alone contains the spectra of 10,351 stars down to the 7–8 magnitudes, and this has further been extended by work at Arequipa, whilst Vogel and Müller of Potsdam (*Astro-Phys. Obs. zu Potsdam*, vol. iii. 1882–83) made a spectroscopic survey of the stars down to the 7·5 magnitude between − 1° and + 20° declination. This has again been supplemented by Scheiner (*ibid.*, vol. vii. 1895: "Untersuchungen über die Spectra der helleren Sterne"), and by Vogel and Wilsing (*ibid.*, vol. xii. 1899: "Untersuchungen über die Spectra von 528 Sternen"). Lockyer (*Phil. Trans.*, vol. clxxxiv. A, 1893) in 1892 published a series of large-scale photographs of the brighter stars, and more recently McClean (*Phil. Trans.*, vol. cxci. A, 1898) has completed a spectroscopic survey of the stars of both hemispheres down to the 3½ magnitude. For the study and investigation of special types of stars, the researches of Dunér on the red stars, made at Upsala, and those of Keeler and Campbell on the bright-line stars, made at the Lick Observatory, deserve mention. For the study of stellar spectra the use of prisms in slit or objective-prism spectroscopes has predominated, though more recently the use of specially ruled gratings has been attended by some degree of success at the Yerkes Observatory.

Several new stars have also been discovered by their spectra by Pickering in his routine work of charting the spectra of the stars in different portions of the sky. The photographic plate containing their peculiar spectra was, however, not examined in many cases until the star had died down again.

Spectrum analysis also opened up another field of inquiry, viz. that of the motion of the stars in the line of sight, based on the process of reasoning due to Doppler, and accordingly named Doppler's Principle ("Ueber das farbige Licht der Doppelsterne," . . . *Abhandl. der K. Böhmischen Ges. d. Wiss.* V. Folge, 2 Bd. 1843.)

The observatories of Greenwich and Potsdam were among the first to apply this to the stars, and more recently Campbell at Lick, Newall at Cambridge, and Belopolsky at Pulkowa have made use of the same principle with enormous success.

It was also discovered that there are certain classes of stars having a large component velocity in the line of sight, which changes its direction from time to time, and in many such cases orbital motion has been proven, as in the case of Algol.

Another class of binary stars has also been discovered spectroscopically and explained by Doppler's principle. I refer to the stars known as spectroscopic binaries, in which the spectrum lines of one luminous source reciprocate over those from the other source of light, according as one is moving towards or away from the earth. This displacement of the spectrum lines led to the discovery of the duplicity of β Aurigæ, and ζ Ursæ Majoris by Pickering (*Am. Jour.* [3], 39, p. 46, 1890).

Several other such stars have now been detected, notably β Lyræ, and lastly Capella, discovered independently by Campbell (*Astro-Phys. Jour.*, vol. x. p. 177) at Lick, and Newall (*Monthly Notices*, vol. lx. p. 2, 1899) at Cambridge.

The progress of the new astronomy is so closely bound up with that of photography that I shall briefly call to mind some of the many achievements in which photography has aided the astronomer.

Daguerre's invention in 1839 was almost immediately tried with the sun and moon, J. W. Draper and the two Bonds in America, Warren de la Rue in this country, and Foucault and Fizeau in France, being among the pioneers of celestial photography; but no real progress seems to have been made until after the introduction of the collodion process. Sir John Herschel in 1847 suggested the daily self-registration of the sun-spots to supersede drawings; and in 1857 the De la Rue photo-heliograph was installed at Kew. From 1858–72 a daily record was maintained by the Kew photo-heliograph, when the work was discontinued. Since 1873 the Kew series has been continued at Greenwich, and is supplemented by pictures from Dehra Dûn in India and from Mauritius. The standard size of the sun's disc on these photographs has now been for many years 8 inches, though for some time a 12-inch series was kept up.

The first recorded endeavour to employ photography for eclipse work dates back to 1851, when Berowsky obtained a daguerreotype of the solar prominences during the total eclipse. From that date nearly every total eclipse of the sun has been studied by the aid of photography.

In 1860 the first regularly planned attack on the problem by means of photography was made, when De la Rue and Secchi successfully photographed the prominences and traces of the corona, but it was not until 1869 that Prof. Stephen Alexander obtained the first good photograph of the corona.

In recent years, from 1893 until the total eclipse which occurred last May, photography has been employed to secure large-scale pictures of the corona. These were inaugurated in 1893 by Prof. Schaeberle, who secured a 4-inch picture of the eclipsed sun in Chili: these have been exceeded by Prof. Langley, who obtained a 15-inch picture of the corona in North Carolina during the eclipse of May 1900.

Photography also supplied the key to the question of the prominences and corona being solar appendages, for pictures of the eclipse sun taken in Spain in 1860 terminated this dispute with regard to the prominences, and finally to the corona in 1871.

In 1875, in addition to photographing the corona, attempts were made to photograph its spectrum, and at every eclipse since then the sensitised plate has been used to record both the spectrum of the chromosphere and the corona. The spectrum of the lower layers of the chromosphere were first successfully photographed during the total eclipse of 1896 in Nova Zembla by Mr. Shackleton, though seen by Young as early as 1870, and a new value was given to the wave-length of the coronal line (wrongly mapped by Young in 1869) from photographs taken by Mr. Fowler during the eclipse of 1898 (India).

Lunar photography has occupied the attention of various physicists from time to time, and when Daguerre's process was first enunciated, Arago proposed that the lunar surface should be studied by means of the photographically produced images. In 1840 Dr. Draper succeeded in impressing a daguerreotype plate with a lunar image by the aid of a 5-inch refractor. The earliest lunar photographs, however, shown in England were due to Prof. Bond, of the United States. These he exhibited at the Great Exhibition in 1851. Dancer, the optician, of Manchester, was, perhaps, the first Englishman who secured lunar images, but they were of small size (Abney, "Photography").

Another skilful observer was Crookes, who obtained images of 2 inches diameter, with an 8-inch refractor of the Liverpool Observatory. In 1852 De la Rue began experimenting in lunar photography. He employed a reflector of some 10 feet focal length and about 13 inches diameter. A very complete account of his methods is given in a paper read before the British Association. Mr. Rutherfurd at a later date having tried an 11½-inch refractor, and also a 13-inch reflector, finally constructed a photographic refracting telescope, and produced some of the finest pictures of the moon that were ever taken until recent years. Also Henry Draper's picture of the moon taken Sept. 3, 1863, remained unsurpassed for a quarter of a century.

Admirable photographs of the lunar surface have been published in recent years by the Lick Observatory and others. I myself devoted considerable attention to this subject at one time; but only those surpassing anything before attempted have been published in 1896–99 by MM. Loëwy and Puiseux, taken with the Equatorial Coudé of the Paris Observatory.

Star prints were first secured at Harvard College, under the direction of W. C. Bond, in 1850; and his son, G. P. Bond, made in 1857 a most promising start with double-star measurements on sensitive plates, his subject being the well-known pair in the tail of the Great Bear. The competence of the photographic method to meet the stringent requirements of exact astronomy was still more decisively shown in 1866 by Dr. Gould's determination from his plates of nearly fifty stars in the Pleiades. Their comparison with Bessel's places for the same objects proved that the lapse of a score of years had made no difference in the configuration of that immemorial cluster; and Prof. Jacoby's recent measures of Rutherfurd's photographs taken in 1872 and 1874 enforce the same conclusion.

The above facts are so forcible that no wonder that at the Astrophotographic Congress held in Paris in 1887 it was decided to make a photographic survey of the heavens, and now eighteen photographic telescopes of 13 inches aperture are in operation in various parts of the world, for the purpose of preparing the international astrographic chart, and it was hoped that the catalogue plates would be completed by 1900.

Photography has been applied so assiduously to the discovery of minor planets that something like 450 are now known, the most noteworthy, perhaps, as regards utility being the discovery of Eros (433) in 1898 by Herr Witt at the Observatory Urania, near Berlin.

With regard to the application of photography to recording the form of various nebulæ, it is interesting to quote a passage from Dick's "Practical Astronomer," published in 1845, as opposed to Herschel's opinion that the photography of a nebula would never be possible.

"It might, perhaps, be considered as beyond the bounds of probability to expect that even the distant nebulæ might thus be fixed, and a delineation of their objects produced, which shall be capable of being magnified by microscopes. But we ought to consider that the art is only in its infancy, and that plates of a more delicate nature than those hitherto used may yet be prepared, and that other properties of light may yet be discovered, which shall facilitate such designs. For we ought now to set no boundaries to the discoveries of science, and to the practical applications of scientific discovery, which genius and art may accomplish."

It was not, however, until 1880 that Draper first photographed the Orion Nebula, and later by three years I succeeded in doing the same thing with an exposure of only thirty-seven minutes. In December 1885 the brothers Henry by the aid of photography found that the Pleiades were involved in a nebula, part of which, however, had been seen by myself (*Monthly Notices*, vol. xl. p. 376) with my 3-foot reflector in February 1880, and later, February 1886; it was also partly discerned at Pulkowa with the 30-inch refractor then newly erected.

Still more nebulosity was shown by Dr. Roberts's photographs (*ibid.*, vol. xlvii. p. 24), taken with his 20-inch reflector in October and December 1886, when the whole western side of the group was shown to be involved in a vast nebula, whilst a later photograph taken by MM. Henry early in 1888 showed that practically the whole of the group was a shoal of nebulous matter.

In 1881 Draper and Janssen recorded the comet of that year by photography.

Huggins (*Proc. Roy. Soc.*, vol. xxxii. No. 213) succeeded in photographing a part of the spectrum of the same object (Tebbutt's Comet 1881, II.) on June 24, and the Fraunhofer lines were amongst the photographic impressions, thus demonstrating that at least a part of the continuous spectrum is due to reflected sunlight. He also secured a similar result from Comet Wells (*Brit. Assoc. Report*, 1882, p. 442).

I propose to consider the question of the telescope on the following lines: (1) The refractor and reflector from their inception to their present state. (2) The various modifications and improvements that have been made in mounting these instruments, and (3) the instrument that has lately been introduced by a combination of the two, refractor and reflector, a striking example of which exists now at the Paris Exhibition.

At a meeting of the British Association held nearly half a century ago (1852) (Belfast) Sir David Brewster showed a plate of rock crystal worked in the form of a lens which had been recently found in Nineveh. Sir David Brewster asserted that this lens had been destined for optical purposes, and that it never was a dress ornament.

That the ancients were acquainted with the powers of a magnifying lens may be inferred from the delicacy and minuteness of the incised work on their seals and intaglios, which could only have been done by an eye aided by a lens of some sort.

There is, however, no direct evidence that the ancients were really acquainted with the refracting telescope, though Aristotle speaks of the tubes through which the ancients observed distant objects, and compares their effect to that of a well from the bottom of which the stars may be seen in daylight ("De Gen. Animalium," lib. v.) As an historical fact without any equivocations, however, there is no serious doubt that the telescope was invented in Holland.

The honour of being the originator has been claimed for three men, each of whom has had his partisans. Their names are Metius, Lippershey and Janssen.

Galileo himself says that it was through hearing that some one in France or Holland had made an instrument which magnified distant objects that he was led to inquire how such a result could be obtained.

The first publisher of a result or discovery, supposing such discovery to be honestly his own, ranks as the first inventor, and there is little doubt that Galileo was the first to show the world how to make a telescope (Newcomb's "Astronomy," p. 108). His first telescope was made whilst on a visit to Venice, and he there exhibited a telescope *magnifying three times*: this was in May 1609. Later telescopes which emanated from the hands of Galileo magnified successively four, seven and thirty times. This latter number he never exceeded.

Greater magnifying power was not attained until Kepler explained the theory and some of the advantages of a telescope made of two convex lenses in his "Catoptrics" (1611). The first person to actually apply this to the telescope was Father Scheiner, who describes it in his "Rosa Ursina" (1630), and Wm. Gascoigne was the first to appreciate practically the chief advantages by his invention of the micrometer and application of telescopic sights to instruments of precision.

It was, however, not until about the middle of the seventeenth century that Kepler's telescope came to be nearly universal, and then chiefly because its field of view exceeded that of the Galilean.

The first powerful telescopes were made by Huyghens, and with one of these he discovered Titan (Saturn's brightest satellite): his telescopes magnified from forty-eight to ninety-two times, were about 2⅓ inches aperture, with focal lengths ranging from 12 to 23 feet. By the aid of these he gave the first explanation of Saturn's ring, which he published in 1659.

Huyghens also states that he made object-glasses of 170 feet and 210 feet focal length; also one 300 feet long, but which magnified only 600 times; he also presented one of 123 feet to the Royal Society of London.

Auzout states that the best telescopes of Campani at Rome magnified 150 times, and were of 17 feet focal length. He himself is said to have made telescopes of from 300 to 600 feet focus, but it is improbable that they were ever put to practical use. Cassini discovered Saturn's fifth satellite (Rhea) in 1672, with a telescope made by Campani, magnifying about 150 times, whilst later, in 1684, he added the third and fourth satellites of the same planet to the list of his discoveries.

Although these telescopes were unwieldy, Bradley, with his usual persistency, actually determined the diameter of Venus in 1722 with a telescope of 212 feet focal length.

With such cumbersome instruments many devices were invented of pointing these *aërial telescopes*, as they were termed, to various parts of the sky. Huyghens contrived some ingenious arrangements for this purpose, and also for adjusting and centreing the eye-piece, the object-glass and eye-piece being connected by a long braced rod.

It was not, however, until Dolland's invention of the achromatic object-glass in 1757–58 that the refracting telescope was materially improved, and even then the difficulty of obtaining large blocks of glass free from striæ limited the telescope as regards aperture, for even at the date of Airy's report we have seen that 12 inches was about the maximum aperture for an object-glass.

The work of improving glass dates back to 1784, when Guinand began experimenting with the manufacture of optical flint glass.

He conveyed his secrets to the firm of Fraunhofer and Utzschneider, whom he joined in 1805, and during the period he was there they made the 9·6 inches object-glass for the Dorpat telescope.

Merz and Mädler, the successors of Fraunhofer, carried out successfully the methods handed down to them by Guinand and Fraunhofer.

Guinand communicated his secrets to his family before his death in 1823, and they entered into partnership with Bontemps. The latter afterwards joined the firm of Chance Bros., of Birmingham, and so some of Guinand's work came to England.

At the present day MM. Feil, of Paris, who are direct descendants of Guinand and Messrs. Chance Bros., of Birmingham, are the best known manufacturers of large discs of optical glass.

It is related in history that Ptolemy Euergetes had caused to be erected on a lighthouse at Alexandria a piece of apparatus for discovering vessels a long way off; it has also been maintained that the instrument cited was a concave reflecting mirror, and it is possible to observe with the naked eye images formed by a concave mirror, and that such images are very bright.

Also the Romans were well acquainted with the concentrating power of concave mirrors, using them as burning mirrors, as they were called. The first application of an eye lens to the image formed by reflection from a concave mirror appears to have been made by Father Zucchi, an Italian Jesuit. His work was published in 1652, though it appears he employed such an instrument as early as 1616. The priority, however, of describing, if not making, a practical reflecting telescope belongs to Gregory, who, in his "Optica Promota," 1663, discusses the forms of images of objects produced by mirrors. He was well aware of the failure of all attempts to perfect telescopes by using lenses of various curvature, and proposed the form of reflecting telescope which bears his name.

Newton, however, was the first to construct a reflecting telescope, and with it he could see Jupiter's satellites, &c. Encouraged by this, he made another of 6½ inches focal length, which magnified thirty-eight times, and this he presented to the Royal Society on the day of his election to the Society in 1671.

To Newton we owe also the idea of employing pitch, used in the working of the surfaces.

A third form of telescope was invented by Cassegrain in 1672. He substituted a small convex mirror for the concave mirror in Gregory's form, and thus rendered the telescope a little shorter.

Short also, from 1730–68, displayed uncommon ability in the manufacture of reflecting telescopes, and succeeded in giving true parabolic and elliptic figures to his specula, besides obtaining a high degree of polish upon them. In Short's first telescopes the specula were of glass, as suggested by Gregory; but it was not until after Liebig's discovery of the process of depositing a film of metallic silver upon a glass surface from a salt in solution that glass specula became almost universal, and thus replaced the metallic ones of earlier times.

Shortly after the announcement of Liebig's discovery Steinheil (*Gaz. Univ. d'Augsburg*, March 24, 1856)—and later, independently, Foucault (*Comptes rend.*, vol. xliv. February 1857)—proposed to employ glass for the specula of telescopes, and, as is well known, this is done in all the large reflectors of to-day.

I now propose to deal with the various steps in the development of the telescope, which have resulted in the three forms that I take as examples of the highest development at the present time. These are the Yerkes telescope at Chicago, my own 5-foot reflector, and the telescope recently erected at the Paris Exhibition, dealing not only with the mountings, but with the principles of construction of each. When the telescope was first used all could be seen by holding it in the hand. As the magnifying power increased, some kind of support would become absolutely necessary, and this would take the form of the altitude and azimuth stand, and the motion of the heavenly bodies would doubtless suggest the parallactic or equatorial movement, by which the telescope followed the object by one movement of an axis placed parallel to the pole. This did not come, however, immediately. The long focus telescopes of which I have spoken were sometimes used with a tube, but more often the object-glass was mounted in a long cell and suspended from the top of a pole, at the right height to be in a line between the observer and the object to be looked at; and it was so arranged that by means of a cord it could be brought into a fairly correct position. Notwithstanding the extreme awkwardness of this arrangement, most excellent observations were made in the seventeenth century by the users of these telescopes. Then the achromatic telescope was invented and mechanical mountings were used, with circles for finding positions, much as we have them now. I have already mentioned the rivalry between the English and German forms of mountings, and Airy's preference for the English form. The general feeling amongst astronomers has, however, been largely in favour of the German mounting for refractors, due, no doubt, to a great extent, to the enormous advance in engineering skill. We have many examples of this form of mounting. A list of the principal large refracting and reflecting telescopes now existing is given at the end of this paper. All the refractors in this list, with the exception of the Paris telescope of 50 inches, and the Greenwich telescope of 28 inches, are mounted on the German form. Some of these carry a reflector as well, as, for instance, the telescope lately presented to the Greenwich Observatory by Sir Henry Thompson, which, in addition to a 26-inch refractor, carries a 30-inch reflector at the other end of the declination axis, such as had been previously used by Sir William Huggins and Dr. Roberts; the last, and perhaps the finest, example of the German form being the Yerkes telescope at Chicago.

The small reflector made by Sir Isaac Newton, probably the first ever made, and now at the Royal Society, is mounted on a ball, gripped by two curved pieces, attached to the body of the telescope, which allows the telescope to be pointed in any direction. We have not much information as to the mounting of early reflectors. Sir William Herschel mounted his 4-foot telescope on a rough but admirably-planned open-work mounting, capable of being turned round, and with means to tilt the telescope to any required angle. This form was not very suitable for picking up objects or determining their position, except indirectly; but for the way it was used by Sir William Herschel it was most admirably adapted: the telescope being elevated to the required angle, it was left in that position, and became practically a transit instrument. All the objects passing through the field of view (which was of considerable extent, as the eyepiece could be moved in declination) were observed, and their places in time and declination noted, so that the positions of all these objects in the zone observed were obtained with a considerable degree of accuracy. It was on this plan that Sir John Herschel made his general catalogue of nebulæ, embracing all the nebulæ he could see in both hemispheres; a complete work by one man that is almost unique in the history of astronomy.

Sir William Herschel's mounting of his 4-foot reflector differs in almost every particular from the mountings of the long focus telescopes we have just spoken of. The object-glass was at a height, the reflector was close to the ground. There was a tube to one telescope, but not to the other. The observer in one case stood on the ground, in the other he was on a stage at a considerable elevation. One pole sufficed with a cord for one; a whole mass of poles, wheels, pulleys and ropes surrounded the other. In one respect only were they alike—they both did fine work.

Lassell seems to have been the first to mount a reflector equatorially. He, like Herschel, made a 4-foot telescope, and this he mounted in this way. Lord Rosse mounted his telescopes somewhat after the manner of Sir William Herschel. The present Earl has mounted a 3-foot equatorially.

A 4-foot telescope was made by Thomas Grubb for Melbourne, and this he mounted on the German plan. The telescope being a Cassegrain, the observer is practically on the ground level. A somewhat similar instrument exists at the Paris Observatory. Lassell's 4-foot was mounted in what is called a fork mounting, as is also my own 5-foot reflector, and this in some ways seems well adapted for reflectors of the Newtonian kind.

We now come to the Paris telescope. This is really the result of the combination of a reflector and a refractor. I cannot say when a plane mirror was first used to direct the light into a telescope for astronomical purposes. It seems first to have been suggested by Hooke, who, at a meeting of the Royal Society, when the difficulty of mounting the long focus lenses of Huyghens was under discussion, pointed out that all difficulties would be done away with if, instead of giving movement to the huge telescope itself, a plane mirror were made to move in front of it (Lockyer, "Star-gazing," p. 453).

The Earl of Crawford, then Lord Lindsay, used a heliostat to direct the rays from the sun, on the occasion of the transit of Venus, through a lens of 40 feet focal length, in order to obtain photographs, and it was also largely used by the American observers on the same occasion.

Monsieur Loëwy at Paris proposed in 1871 a most ingenious telescope made by a combination of two plane mirrors and an achromatic object-glass, which he calls a Coudé telescope, which has some most important advantages. Chief amongst these are that the observer sits in perfect comfort at the upper end of the polar axis, whence he need not move, and by suitable arrangements he can direct the telescope to any part of the visible heavens. Several have been made in France, including a large one of 24 inches aperture, erected at the Paris Observatory, and which has already made its mark by the production of perhaps the best photographs of the moon yet obtained. I have already spoken of Lord Lindsay and his 40-foot telescope, fed, as it were, with light from a heliostat. This is exactly the plan that has been followed in the design of the large telescope in the Paris Exhibition. But in place of a lens of 4 inches aperture and a heliostat a few inches larger, the Paris telescope has a plane mirror of 6 feet and a lens exceeding 4 feet in diameter, with a focal length of 186 feet. The cost of a mounting on the German plan and of a dome to shelter such an instrument would have been enormous. The form chosen is at once the best and cheapest. One of the great disadvantages is that from the nature of things it cannot take in the whole of the heavens. The heliostat form of mounting of the plane mirror causes a rotation of the image in the field of view which in many lines of research is a strong objection. There is much to be said on the other side. The dome is dispensed with, the tube, the equatorial mounting and the rising floor are not wanted. The mechanical arrangements of importance are confined to the mounting of the necessary machinery to carry the large plane mirror and move it round at the proper rate. The telescope need not have any tube (that to the Paris telescope is, of course, only placed there for effect), as the flimsiest covering is enough if it excludes false light falling on the eye-end; and, more important than all, the observer sits at his ease in the dark chamber. This question of the observer, and the conditions under which he observes, is a most important one as regards both the quality and quantity of the work done.

We have watched the astronomer, first observing from the floor level, then mounted on a high scaffold like Sir William Herschel, Lassell and Lord Rosse; then, starting again from the floor level and using the early achromatic telescope; then, as these grew in size, climbing up on observing chairs to suit the various positions of the eye-end of the telescope, as we see in Mr. Newall's great telescope; then brought to the floor again by that excellent device of Sir Howard Grubb, the rising floor. This is in use with the Lick and the Yerkes telescopes, where the observer is practically always on the floor level, though constant attention is needed, and the circular motion has to be provided for by constant movement, to say nothing of the danger of the floor going wrong. Then we have the ideal condition, as in the Equatorial Coudé at the Paris Observatory, where the observer sits comfortably sheltered and looks down the telescope, and from this position can survey the whole of the visible heavens. The comfort of the observer is a most important matter, especially for the long exposures that are given to photographic plates, as well as for continued visual work. In such a form of telescope as that at Paris the heliostat form of mounting the plane mirror is most suitable, notwithstanding the rotation of the image. But there is another way in which a plane mirror can be mounted, and that is on the plan first proposed by Auguste many years ago, and lately brought forward again by Mons. Lippman, of Paris, and that is by simply mounting the plane mirror on a polar axis and parallel therewith, and causing this mirror to rotate at half the speed of the earth's rotation. Any part of the heavens seen by any person reflected from this mirror will appear to be fixed in space, and not partake of the apparent movement of the earth, so long as the mirror is kept moving at this rate. A telescope, therefore, directed to such a mirror can observe any heavenly body as if it were in an absolutely fixed position so long as the angle of the mirror shall not be such as to make the reflected beam less than will fill the object-glass. There is one disadvantage in the cœlostat, as this instrument is called, and that is its suitability only for regions near the equator. The range above and below, however, is large enough to include the greater portion of the heavens, and that portion in which the solar system is included. Here the telescope must be moved in azimuth for different portions of the sky, as is fully explained by Prof. Turner in vol. lvi. of the *Monthly Notices*, and it therefore becomes necessary to provide for moving the telescope in azimuth from time to time as different zones above or below the equator are observed. No instrument yet devised is suitable for all kinds of work, but this form, notwithstanding its defects, has so many and such important advantages that I think it will obviate the necessity of building any larger refractors on the usual models. The cost of producing a telescope much larger than the Yerkes on that model, in comparison with what could be done on the plan I now advocate, renders it most improbable that further money will be spent in that way. It may be asked, What are the lines of research which could be taken up by a telescope of this construction, and on what lines should the telescope be built? I will endeavour to answer this. All the work that is usually done by an astronomical telescope, excepting very long-continued observations, can be equally well done by the fixed telescope. But there are some special lines for which this form of research is admirably suited, such as photographs of the moon, which would be possible with a reflecting mirror of, say, 200 feet focal length, giving an image of some 2 feet diameter in a primary focus, or a larger image might be obtained either by a longer focus mirror or by a combination. It might even be worth while to build a special cœlostat for lunar photography, provided with an adjustment to the polar axis and a method of regulating the rate of clock to correct the irregular motion of the moon, and thus obtain absolutely fixed images on the photographic plate.

The advantage of large primary images in photography is now fully recognised. For all other kinds of astronomical photography a fixed telescope is admirably adapted; and so with all spectroscopic investigations, a little consideration will show that the conditions under which these investigations can be pursued are almost ideal. As to the actual form such a construction would take, we can easily imagine it. The large mirror mounted as a cœlostat in the centre; circular tracts round this centre, on which a fan-shaped house can be travelled round to any azimuth, containing all the necessary apparatus for utilising the light from the large plane mirror, so as to be easily moved round to the required position in azimuth for observation. In place of a fan-shaped house movable round the plane mirror, a permanent house might encircle the greater portion round the mirror, and in this house the telescope or whatever optical combination is used might be arranged on an open framework, supported on similar rails, so as to run round to any azimuth required. The simplicity of the arrangement and the enormous saving in cost would allow in any well-equipped observatory the use of a special instrument for special work. The French telescope has a mirror about 6 feet in diameter and a lens of about 4 feet. This is a great step in advance over the Yerkes telescope, and it may be some time before the glass for a lens greater than 50 inches diameter will be made, as the difficulty in making optical glass is undoubtedly very great. But with the plane mirror there will be no such difficulty, as 6 feet has already been made; and so with a concave mirror there would be little difficulty in beginning with 6 feet or 7 feet. The way in which the mirror would be used, always hanging in a band, is the most favourable condition for good work, and the absence of motion during an observation, except of course that of the plane mirror (which could be given by floating the polar axis and suitable mechanical arrangements, a motion of almost perfect regularity).

One extremely important thing in using silver or glass mirrors is the matter of resilvering from time to time. Up to quite recently the silvering of my 5-foot mirror was a long, uncertain, and expensive process. Now we have a method of silvering mirrors that is certain, quick, and cheap. This takes away the one great disability from the silver or glass reflecting telescope, as the surface of silver can now be renewed with greater ease and in less time than the lenses of a large refracting telescope could be taken out and cleaned. It may be that we shall revert to speculum metal for our mirrors, or use some other deposited metal on glass; but even as it is we have the silvered glass reflector, which at once allows an enormous advance in power. To do justice to any large telescope it should be erected in a position, as regards climate, where the conditions are as favourable as possible.

The invention of the telescope is to me the most beautiful ever made. Familiarity both in making and in using has only increased my admiration. With the exception of the microphone of the late Prof. Hughes, which enabled one to hear otherwise inaudible sounds, sight is the only sense that we have been able to enormously increase in range. The telescope enables one to see distant objects as if they were at, say, one-five-thousandth part of their distance, while the microscope renders visible objects so small as to be almost incredible. In order to appreciate better what optical aid does for the sense of sight, we can imagine the size of an eye, and therefore of a man, capable of seeing in a natural way what the ordinary eye sees by the aid of a large telescope, and, on the other hand, the size of a man and his eye that could see plainly small objects as we see them under a powerful microscope. The man in the first case would be several miles in height, and in the latter he would not exceed a very small fraction of an inch in height.

Photography also comes in as a further aid to the telescope, as it may possibly be to the microscope. For a certain amount of light is necessary to produce sensation in the eye. If this light is insufficient nothing is seen; but owing to the accumulative effect of light on the photographic plate, photographs can be taken of objects otherwise invisible, as I pointed out years ago, for in photographs I took in 1883 stars were shown on photographic plates that I could not see in the telescope. All photographs, when closely examined, are made up of a certain number of little dots, as it were, in the nature of stippling, and it is a very interesting point to consider the relation of the size and separation of these dots that form the image, and the rods and cones of the reckoner which determines the power of the eye.

Many years ago I tried to determine this question. I first took a photograph of the moon with a telescope of very short focus (as near as I could get it to the focus of the eye itself, which is about half an inch). The resulting photograph measured one two-hundredth of an inch in diameter, and when examined again with a microscope showed a fair amount of detail, in fact, very much as we see the moon with the naked eye; making a picture of the moon by hand on such a scale that each separate dot of which it was made corresponded with each separate sensitive point of the retina employed when viewing the moon without optical aid, I found, on looking at this picture at the proper distance, that it looked exactly like a real moon. In this case the distance of the dots was constant, making them larger or smaller forming the light or shade of the picture.

I did not complete these experiments, but as far as I went I thought that there was good reason to believe that we could in this way increase the defining power of the eye. It is a subject well worthy of further consideration.

I know that in this imperfect and necessarily brief address I have been obliged to omit the names of many workers, but I cannot conclude without alluding to the part that this Association has played in fostering and aiding Astronomy. A glance through the list of money grants shows that the help has been most liberal. In my youth I recollect the great value that was put on the British Association Catalogue of Stars; we know the help that was given in its early days to the Kew Observatory; and the Reports of the Association show the great interest that has always been taken in our work. The formation of a separate Department of Astronomy is, I hope, a pledge that this interest will be continued, to the advantage of our science.

## SECTION B.

### CHEMISTRY.

OPENING ADDRESS BY PROF. W. H. PERKIN, JUN., PH.D., F.R.S., PRESIDENT OF THE SECTION.

### *The Modern System of Teaching Practical Inorganic Chemistry and its Development.*

IN choosing for the subject of my Address to-day the development of the teaching of practical inorganic chemistry I do so, not only on account of the great importance of the subject, but also because it does not appear that this matter has been brought before this Section, in the President's Address at all events, during the last few years.

In dealing generally with the subject of the teaching of chemistry as a branch of science it may be well in the first place to consider the value of such teaching as a means of general education, and to turn our attention for a few minutes to the development of the teaching of science in schools.

There can be no doubt that there has been great progress in the teaching of science in schools during the last forty years, and this is very evident from the perusal of the essay, entitled "Education: Intellectual, Moral, and Physical," which Herbert Spencer wrote in 1859. After giving his reasons for considering the study of science of primary importance in education, Herbert Spencer continues: "While what we call civilisation could never have arisen had it not been for science, science forms scarcely an appreciable element in our so-called civilised training."

From this it is apparent that science was not taught to any appreciable extent in schools at that date, though doubtless in some few schools occasional lectures were given on such scientific subjects as physiology, anatomy, astronomy, and mechanics.

Herbert Spencer's pamphlet appears to have had only a very gradual effect towards the introduction of science into schemes of education. For many years chemical instruction was only given in schools at the schoolroom desk, or at the best from the lecture table, and many of the most modern of schools had no laboratories.

The first school to give any practical instruction in chemistry was apparently the City of London School, at which, in the year 1847, Mr. Hall was appointed teacher of chemistry, and there he continued to teach until 1869.[1] Besides the lecture theatre and a room for storing apparatus, Mr. Hall's department contained a long room, or rather passage, leading into the lecture theatre, and closed at each end with glass doors. In this room, which was fitted up as a laboratory, and used principally as a preparation room for the lectures, Mr. Hall performed experiments with the few boys who assisted him with his lectures. As accommodation was at that time strictly limited, he used to suggest simple experiments and encourage the boys to carry them out at home, and afterwards he himself would examine the substances which they had made.

From this small beginning the teaching of chemistry in the City of London School rapidly developed, and this school now possesses laboratories which compare favourably with those of any school in the country.

The Manchester Grammar School appears to have been one of the first to teach practical chemistry. In connection with this school a small laboratory was built in 1868; this was replaced by a larger one in 1872, and the present large laboratories, under the charge of Mr. Francis Jones, were opened in 1880.

Dr. Marshall Watts, who was the first science master in this school, taught practical chemistry along with the theoretical work from the commencement in 1868.

As laboratories were gradually multiplied it might be supposed that boys were given the opportunity to carry out experiments which had a close connection with their lecture-room courses. But the programme of laboratory work which became all but universal was the preparation of a few gases, followed by the practice of qualitative analysis. The course adopted seems to have been largely built up on the best books of practical chemistry in use in the colleges at that time; but it was also, no doubt, largely influenced by the requirements of the syllabus of the Science and Art Department, which contained a scheme for teaching practical chemistry.[1] Even down to quite recent times it was in many schools still not considered essential that boys should have practical instruction in connection with lectures in chemistry.

A Report issued in 1897 by a special Committee appointed by the Technical Education Board of the London County Council adduces evidence of this from twenty-five secondary schools in London, in which there were 3960 boys learning chemistry. Of these 1698 boys, or 43 per cent., did no practical work whatever; 955 boys, or 24 per cent., did practical work, consisting of a certain amount of preparation of gases, together with qualitative analysis; but of these latter 743, or 77 per cent., had not reached the study of the metals in their theoretical work, so that their testing work can have been of little educational value. It was also found that in the case of 655, or 68 per cent. of the total number of boys taking practical work, the first introduction to practical chemistry was through qualitative analysis.

But some years before this Report was issued a movement had begun which was destined to have a far-reaching effect. A Report "on the best means for promoting Scientific Education in Schools" having been presented to the Dundee Meeting of this Association in 1867, and published in 1868, a Committee of the British Association was appointed in 1887 "for the purpose of inquiring and reporting upon the present methods of teaching chemistry." The well-known Report which this Committee presented to the Newcastle Meeting in 1889 insisted that it was worth while to teach chemistry in schools, not so much for the usefulness of the information imparted as for the special mental discipline it afforded if the scientific method of investigating nature were employed. It was argued that "learners should be put in the attitude of discoverers, and led to make observations, experiments, and inferences for themselves." And since there can be little progress without measurement, it was pointed out that the experimental work would necessarily be largely of a quantitative character.

Prof. H. E. Armstrong, in a paper read at a conference at the Health Exhibition five years before this, had foreshadowed much that was in this Report. He also drew up a detailed scheme for "a course of elementary instruction in physical science," which was included in the Report of the Committee, and it cannot be doubted that this scheme and the labours of the Committee have had a very marked influence on the development of the teaching of practical chemistry in schools. That this influence has been great will be admitted when it is understood that schemes based on the recommendation of the Committee are now included in the codes for both Elementary Day Schools and Evening Continuation Schools. The recent syllabuses for elementary and advanced courses issued by the Incorporated Association of Headmasters and by the Oxford and Cambridge local boards and others are evidently directly inspired by the ideas set forth by the Committee.

The Department of Science and Art has also adopted some of the suggestions of the Committee, and a revised syllabus was issued by the Department in 1895, in which qualitative analysis is replaced by quantitative experiments of a simple form, and by other exercises so framed "as to prevent answers being given by students who have obtained their information from books or oral instruction." This was a very considerable advance, but it must be admitted that there is nothing in the syllabus which encourages, or even suggests, placing the learners in the attitude of discoverers, and this, in the opinion of the Committee of this Association, is vital if the teaching is to have educational value.

Many criticisms have been passed upon the 1889 Report. It has been said that life is much too short to allow of each individual advancing from the known to the unknown, according to scientific methods, and that even were this not so too severe a tax is made upon the powers of boys and girls. In answer to the second point it will be conceded that while it is doubtless futile to try to teach chemistry to young children, on the other hand experience has abundantly shown that the average schoolboy of fourteen or fifteen can, with much success, investigate such problems as were studied in the researches of Black and Scheele, of Priestley and Cavendish and Lavoisier, and it is quite remarkable with what interest such young students carry out this class of work.

It may be well to quote the words which Sir Michael Foster used in this connection in his admirable Presidential Address to this Association in 1899. He said: "The learner may be led to old truths, even the oldest, in more ways than one. He may be brought abruptly to a truth in its finished form, coming straight to it like a thief climbing over a wall; and the hurry and press of modern life tempt many to adopt this quicker way. Or he may be more slowly guided along the path by which the truth was reached by him who first laid hold of it. It is by this latter way of learning the truth, and by this alone, that the learner may hope to catch something at least of the spirit of the scientific inquirer."

---

[1] Mr. A. T. Pollard, M.A., Head Master of the City of London School, has kindly instituted a search among the bound copies of the boys' terminal reports, and informs me that in the School form of Terminal Report a heading for Chemistry was introduced in the year 1847, the year of Mr. Hall's appointment.

[1] I find, on inquiry, that examinations in the Advanced Stage and Honours of Practical Chemistry were first held by the Science and Art Department in 1878, the practical examination being extended to the Elementary Stage in 1882.

I believe that in the determination of a suitable school course in experimental science this principle of historical development is a very valuable guide, although it is not laid down in the 1889 Report of the British Association.

The application of this principle will lead to the study of the solvent action of water, of crystallisation, and of the separation of mixtures of solids before the investigation of the composition of water, and also before the investigation of the phenomena of combustion. It will lead to the investigation of hydrochloric acid before chlorine, and especially to the postponement of atomic and molecular theories, chemical equations, and the laws of chemical combination, until the student has really sufficient knowledge to understand how these theories came to be necessary.

There can be no doubt that this new system of teaching chemistry in schools has been most successful. Teachers are delighted with the results which have already been obtained, and those whom I have had the opportunity of consulting, directly and indirectly, cannot speak too highly of their satisfaction at the disappearance of the old system of qualitative analysis, and the institution of the new order of things. Especially I may mention in this connection the excellent work which is being carried on under the supervision of Dr. Bevan Lean at the Friends' School in Ackworth, where the boys have attained results which are far in advance of anything which would have been thought possible a few years since.

It is, of course, obvious that if a schoolboy is made to take the attitude of a discoverer, his progress may appear to be slow. But does this matter? Most boys will not become professional chemists; but if while at school a boy learns how to learn, and how to "make knowledge"[1] by working out for himself a few problems, a habit of mind will be formed which will enable him in future years to look in a scientific spirit at any new problems which may face him. When school-days are past the details of the preparation of hydrogen may have been forgotten; but if it was really understood at the time that it could not be decided at once whether the gas was derived from the acid or from the metal, or from the water, or in part from the one and in part from the other, an attitude of scepticism and of suspended judgment will have been formed, which will continue to guard from error.

In the new system of teaching chemistry in schools much attention must necessarily be given to weights and measurements; indeed, the work must be largely of a quantitative kind, and it is in this connection that an important note of warning has been sounded by several teachers.[2] They consider, very rightly, that it is important to point out clearly to the scholar that science does not consist of measurement, but that measurement is only a tool in the hand of the inquirer, and that when once sufficient skill has been developed in its use it should be employed only with a distinct object. Measurements should, in fact, be made only in reference to some actual problem which appears to be really worth solving, not in the accumulation of aimless details.

And, of course, all research carried out must be genuine and not sham, and all assumption of the "obvious" must be most carefully guarded against. But the young scholar must, at the same time, not forget that although the scientific method is necessary to enable him to arrive at a result, in real life it is the answer to the problem which is of the most importance.[3]

Although, then, there has been so much discussion, during the last ten years, on the subject of teaching chemistry in schools, and such steady progress has been made towards devising a really satisfactory system of teaching the subject to young boys and girls, it is certainly very remarkable that practically nothing has been said or written bearing on the training which a student who wishes to become a chemist is to undertake at the close of his school-days at the college or university in which his education is continued.

One of the most remarkable points, to my mind, in connection with the teaching of chemistry, is the fact that although the science has been advancing year by year with such unexampled rapidity, the course of training which the student goes through during his first two years at most colleges is still practically the same as it was thirty or forty years ago. Then, as now, after preparing a few of the principal gases, the student devotes the bulk of his first year to qualitative analysis in the dry and wet way, and his second year to quantitative analysis, and, although the methods employed in teaching the latter may possibly have undergone some slight modification, there is certainly no great difference between the routine of simple salt and mixture followed by quantitative analysis practised at the present day and that which was in vogue in the days of our fathers and grandfathers.

Since, then, the present system has held the field for so long, not only in this country but also on the Continent, it is worth while considering whether it affords the best training which a student who wishes to become a chemist can undergo in the short time during which he can attend at a college or university. In considering this matter I was led in the first place to carefully examine old books and other records, with the object of finding out how the present system originated, and I think that valuable and interesting information bearing on the subject may be obtained from a very brief sketch of the rise and development of the present system of teaching chemistry, and especially in so far as it bears on the inclusion of qualitative analysis. Unfortunately, it is not so easy to gain a good historical acquaintance with the matter as I at first imagined would be the case, and this is due in a large measure to the fact that so few of the laboratories which took an active part in the development of the present system of chemical training have left any record of the methods which they employed. In this connection I may, perhaps, be allowed to suggest that it would be a valuable help to the future historian if all prominent teachers of chemistry would leave behind them a brief record of the system of teaching adopted in their laboratories, showing the changes which they had instituted, the object of these changes, and the results which followed their adoption.

There is no doubt that the progress of practical chemistry went largely hand in hand with the progress of theoretical chemistry, for as the latter gradually developed, so the necessity for the determination of the composition, first of the best known, and then of the rarer minerals and other substances, became more and more marked.

The analytical examination of substances in the dry way was employed in very early times in connection with metallurgical operations, and especially in the determination of the presence of valuable constituents in samples of minerals. Cupellation was used by the Greeks in the separation of gold and silver from their ores and in the purification of these metals. Geber knew that the addition of nitre to the ore facilitated the separation of gold and silver, and subsequently Glauber (1604–1668) called attention to the fact that many commoner metals could easily be separated from their ores with the aid of nitre.

But it was not till the eighteenth century that any marked progress was made in analysis in the dry way, and the progress which then became rapid was undoubtedly due to the discovery of the blowpipe, and to the introduction of its use into analytical operations. The blowpipe is mentioned for the first time in 1660, in the transactions of the Accademia del Cimento of Florence, but the first to recommend its use in chemical operations was Johann Andreas Cramer in 1739. The progress of blowpipe analysis was largely due to Gahn (1745–1818), who spent much time in perfecting its use in the examination of minerals, and it was he who first used platinum wire and cobalt solution in connection with blowpipe analysis. The methods employed by Gahn were further developed by his friend Berzelius (1779–1848), who gave much attention to the matter, and who with great skill and patience gradually worked out a complete scheme of blowpipe analysis, and published it in a pamphlet, entitled "Ueber die Anwendung des Löthrohrs," which appeared in 1820. After the publication of this work blowpipe analysis rapidly came into general use in England France and Germany, and the scheme devised by Berzelius is essentially that employed at the present day.

Indeed, the only notable additions to the methods of analysis in the dry way since the time of Berzelius are the development of flame reactions, which Bunsen worked out with such characteristic skill and ingenuity, and the introduction of the spectroscope.

The necessity for some process other than that of analysis in the dry way seems, in the first instance, to have arisen in quite early times in connection with the examination of drugs, not only on account of the necessity for discovering their constituents, but also as a means of determining whether they were adulterated. In such cases analysis in the dry way was obviously unsuitable, and experience soon showed that the only way to arrive at the desired result was to treat the substance under examination with aqueous solutions of definite substances, the first reagent apparently being a decoction of gallnuts, which is described by Pliny as being employed in detecting adulteration with green vitriol.

The progress made in connection with wet analysis was, however, exceedingly slow, largely owing to the lack of reagents; but as these were gradually discovered wet analysis rapidly developed, especially in the hands of Tachenius, Scheele, Boyle, Hoffman, Margraf, and Bergmann. Boyle (1626–1691) especially had an extensive knowledge of reagents and their application; and, indeed, it was Boyle who first introduced the word "analysis" for those operations by which substances may be recognised in the presence of one another. Boyle knew how to test for silver with hydrochloric acid, for calcium salts with sulphuric acid, and for copper by the blue solution produced by ammonia.

Margraf (1709–1782) introduced prussiate of potash for the detection of iron, and Bergmann (1735–1784) not only introduced new reagents and new methods for decomposing minerals and refractory substances, such as fusion with potash, digestion with nitric acid or hydrochloric acid, but he also was the first to suggest the application of tests in a systematic way, and, indeed, the method of analysis which he developed is on much the same lines as that in use at the present day. He paid special attention to the qualitative analysis of minerals, and gave careful instructions for the analysis of gold, platinum, silver, lead, copper, zinc, and other ores. The work of Scheele (1742–1786) had indirectly a great influence on qualitative analysis, as, although he did not give a general systematic method of procedure in the analysis of substances of unknown composition, yet the methods which he employed in the examination of new substances were so original and exact as to remain models of how qualitative analysis should be conducted.

Great strides in analytical chemistry in the wet way were made through the work of Berzelius, who, by the discovery of new methods, such as the decomposition of silicates by hydrofluoric acid and the introduction of new tests, greatly advanced the art. He paid special attention to perfecting the methods of analysis of mineral waters, and these researches, as well as his work on ores, and particularly his investigation of platinum ores, stamp Berzelius as one of the great pioneers in qualitative and quantitative analytical chemistry.

By the labours of the great experimenters whom I have mentioned qualitative analysis gradually acquired the familiar appearance of to-day, and many books were written with the object of arranging the mass of information which had accumulated, and of thus rendering it available for the student in his efforts to investigate the composition of new minerals and other substances. Among these books may be mentioned the "Handbuch der analytischen Chemie," by H. Rose, and especially the well-known analytical text-books of Fresenius, which have had an extraordinarily wide circulation and passed through many editions.

The work of the great pioneers in analytical chemistry was work done often under circumstances of great difficulty, as before the end of the seventeenth century there were no public institutions of any sort in which a practical knowledge of chemistry could be acquired. Lectures were, of course, given from very early times, but it was not until the time of Guillaume François Rouelle (1703–1770), at the beginning of the eighteenth century, that lectures began to be illustrated by experiments. Rouelle, who was very active as a teacher, numbered among his pupils many men of eminence, such as Lavoisier and Proust, and it was largely owing to his influence that France took such a lead in practical teaching. In Germany progress was much slower, and in our country the introduction of lectures illustrated by experiments seems to have been mainly due to Davy.

When it is considered how slowly experimental work came to be recognised as a means of illustration and education, even in connection with lectures, it is not surprising that in early times practical teaching in laboratories should have been thought quite unnecessary.

The few laboratories which existed in the sixteenth century were built mainly for the practice of alchemy by the reigning princes of the time, and, indeed, up to the beginning of the nineteenth entury, the private laboratories of the great masters were the only schools in which a favoured few might study, but which were not open to the public. Thus we find that Berzelius received in his laboratory a limited number of students who worked mostly at research; these were not usually young men, and his school cannot thus be considered as a teaching institution in the ordinary sense of the word.

The earliest laboratory open for general instruction in Great Britain was that of Thomas Thomson, who, after graduating in Edinburgh in 1799, began lecturing in that city in 1800, and opened a laboratory for the practical instruction of his pupils. Thomson was appointed lecturer in Chemistry in Glasgow University in 1807, and Regius Professor in 1818, and in Glasgow he also opened a general laboratory.

The first really great advance in laboratory teaching is due to Liebig, who, after working for some years in Paris under Gay-Lussac, was appointed in 1824 to be Professor of Chemistry in Giessen. Liebig was strongly impressed with the necessity for public institutions where any student could study chemistry, and to him fell the honour of founding the world-famed Giessen Laboratory, the first public institution in Germany which brought practical chemistry within the reach of all students.

Giessen rapidly became the centre of chemical interest in Germany, and students flocked to the laboratory in such numbers as to necessitate the development of a systematic course of practical chemistry, and in this way a scheme of teaching was devised which, as we shall see later, has served as the foundation for the system of practical chemistry in use at the present day.

When the success of this laboratory had been clearly established, many other towns discovered the necessity for similar institutions, and in a comparatively short time every university in Germany possessed a chemical laboratory. The teaching of practical chemistry in other countries was, however, of very slow growth; in France, for example, Wurtz in 1869 drew attention to the fact that there was at that time only one laboratory which could compare with the German laboratories, namely, that of the École normale supérieure.

In this country the provision of suitable laboratories for the study of chemistry seems to date from the year 1845, when the College of Chemistry was founded in London, an institution which under A. W. Hofmann's guidance rapidly rose to such a prominent position.

In 1851 Frankland was appointed to the chair of chemistry in the new college founded in Manchester by the trustees of John Owens, and here he equipped a laboratory for the teaching of practical chemistry. Under Sir Henry Roscoe this laboratory soon became too small for the growing number of chemical students, a defect which was removed when the new buildings of the college were opened in 1873. In 1849 Alexander Williamson was appointed Professor of Practical Chemistry at University College, London, where he introduced the practical methods of Liebig.

Following these examples, the older universities gradually came to see the necessity for providing accommodation for the practical teaching of chemistry, with the result that well-equipped laboratories have been erected in all the centres of learning in this country.

Since Liebig, by the establishment of the Giessen Laboratory, must be looked upon as the pioneer in the development of practical laboratory teaching, it will be interesting to endeavour to obtain some idea of the methods which he used in the training of the students who attended his laboratory in Giessen. From small beginnings he gradually introduced a systematic course of practical chemistry, and a careful comparison shows that this was similar in many ways to that in use at the present day. The student at Giessen, after preparing the more important gases, was carefully trained in qualitative and quantitative analysis; he was then required to make a large number of preparations, after which he engaged in original research.

Although there is, as far as I have been able to ascertain, no printed record of the nature of the quantitative work and the preparations which Liebig required from his students, the course of qualitative analysis is easily followed, owing to the existence of a most interesting book published for the use of the Giessen students.

In 1846, at Liebig's request, Henry Will, Ph.D., Extraordinary Professor of Chemistry in the University of Giessen, wrote a small book, for use at Giessen, called "Giessen Outlines of Analysis," which shows clearly the kind of instruction given in that laboratory at the time in so far as qualitative analysis is concerned. This book, which contains a preface by Liebig, is particularly interesting on account of the fact that it is evidently the first Introduction to Analysis intended for the training of elementary students which was ever published. In the preface Liebig writes: "The want of an introduction to chemical analysis adapted for the use of a laboratory has given rise to the present work, which contains an accurate description of the course I have followed in my laboratory with great advantage for twenty-five years. It has been prepared at my request by Prof. Will, who has been my assistant during a great part of this period."

This book undoubtedly had a considerable circulation, and was used in most of the laboratories which were in existence at that time, and thus we find, for example, that the English translation which Liebig "hopes and believes will be acceptable to the English public" was the book used by Hofmann for his students at the College of Chemistry. In this book the metals are first divided into groups much in the same way as is done now; each group is then separately dealt with, the principal characteristics of the metals of the group are noted, and their reactions studied. Those tests which are useful in the detection of each metal are particularly emphasised, and the reasons given for selecting certain of them as of special value for the purposes of separating one metal from another.

Throughout this section of the book there are frequent discussions as to the possible methods of the separation, not only of the metals of one group, but of those belonging to different groups; and the whole subject is treated in a manner which shows clearly that Liebig's great object was to make the student think for himself. After studying in a similar manner the behaviour of the principal acids with reagents, the student is introduced to a course of qualitative analysis comprising (1), preliminary examination of solids (2), qualitative analysis of the substance in solution.

Both sections are evidently written with the object, not only of constructing a system of qualitative analysis, but more particularly of clearly leading the student to argue out for himself the methods of separation which he will ultimately adopt. The book concludes with a few tables which differ considerably in design from those in use at the present day, and which are so meagre that the student could not possibly have used them mechanically.
